Medico-Legal Update

CONTENTS

Volume 21, Number 1 **January-March 2021**

1. Psychometric Validation of the Maslach Burnout Inventory (MBI) Adapted to Moroccan Teachers.....1
Abdeslam Amri, Zakaria Abidli, Mounir Bouzaaboul, Ziri Rabea, Ahmed Omar Touhami Ahami, Abdelmajid Soulaymani

2. COVID 19: Evaluate of Liver and Renal Function Tests in Iraqi Patients 7
Abdullah Ali Mohammed, Mahmood Nazar Mustafa, Sura A. Abdulsattar, Ahmed Salam Al-zaidi

3. Assess the Level of Perception Regarding Instructor Caring Behaviour among Nursing Students at SRM College of Nursing.....11
Abirami P.

4. Medical, Human Rights and Legal Analysis of the Existence of Lesbian, Gay, Bisexual, and Transgender in Indonesia.....16
Aditya Yuli Sulistyawan, Tri Rahayu Utami

5. The Role of Kinship and the Effectiveness of Traditional Customary Law on Inheritance System in Berbah, Sleman Regency 20
Agung Basuki Prasetyo

6. Does Education Level Matter in Women's Risk of Early Marriage?: Case Study in Rural Area in Indonesia.....24
Agung Dwi Laksono, Ratna Dwi Wulandari, Ratu Matahari

7. The Border–Non-Border Areas Disparities in Hospital Utilization in Kalimantan Island, Indonesia 29
Agung Dwi Laksono, Ratna Dwi Wulandari

8. Case-Control Analysis of Malaria Incidence in Sukamerindu Health Center Bengkulu City, Indonesia.....35
Agung Sutriyawan, Tenike G. Miranda, Ucu W. Somantri, Hairil Akbar

9. Descriptive Online Survey: Knowledge, Attitudes, and Anxiety During the Period of Pandemic COVID-19 in Indonesia.....42
Agung Sutriyawan, Hairil Akbar, Fibrianti, Intan Pertiwi, Ucu W. Somantri, Lezi Y. Sari

10. Phacoemulsification Under Topical Anaesthesia Combined with Anxiolytic 49
Ahmed Mohammed Al-Samak

11. The Influences of Antenatal Care, Postnatal Care and Early Initiation of Breastfeeding on an Exclusive Breastfeeding Pattern in the Working Area of Manukan Kulon Public Health Center at Surabaya City 53
Azizi Pridasari, Lutfi Agus Salim

12. Applying Strict Liability for Environmental Offenses: Indonesian Perspective 59
Al Halim

13. Investigation of Cutaneous Leishmaniasis Cases in Baghdad Province, Iraq 65
Aliaa F.A. Al-Naimy, Ali B.M. Al-Waaly

14. Forensic Autopsy Study of Abdominal and Pelvic Trauma Due to Road Traffic Injuries 70
Alok Kandpal, Ashok Chanana, Jaspinder Pratap Singh

15. To Compare the Effects of Footwear in Young Female's Postural Balance in Prolonged Standing and Sitting Job . 77
Anandita Sharma, Yamini Sharma, Megha Yadav, Mangalam Kumari, Jyoti Sharma, Sakshi Arora, Akshay Anand

16. Prospective Studies on Pattern of Two Wheeler Injuries in Road Traffic Accidents 82
Arun Prakash K.S., Sanjeev K., Gambhir Singh O.

17. A Review of Studies Assessing Cannabidiol's (CBD) Therapeutic Action and Potentials in Respiratory Diseases . 87
Arwa Fairaq, Sahar El-Ashmony, Yosra AL-Hindi

18. Evaluation the Door-to-Balloon Time in Patient with ST-Elevation Myocardial Infraction (STEMI) in King Abdullah Medical City (KAMC) in Makkah Almukarramah: A Retrospective Single Center Study 92
Arwa Fairaq, Dunia Alfi, Halah Bahakeem, SehamMalki, Raheeq Algarrash, Shroug Allehyani, Yosra Al-Hindi

19. The Adsorption Effect of Pine Resin (***Pinus Merkusii***) in Reducing Hardness ($CaCO_3$) in Clean Water 100
Ashari Rasjid, Syamsuddin S.

20. Assessment of the Knowledge and Attitude of Eligible Couples towards Tubectomy and Vasectomy 107
Ashish Dass, Jaspreet Kaur Dullat, Maninder Singh, Aanchal, Balpreet Kaur, Chandresh, Jahangir

21. Nursing Intervention for Caregivers of Post Autologous Bone Marrow Transplantation Patients at Home 112
Asmaa Farouk Mohamed, Nawal Soliman, Hemat Abd-El-Moneem El-Sayied, Asmaa Talaat

22. Psychological Problems among the Health Workers During Pandemic Covid-19 118
Astabrak A. N. Al-Hamoodi, Burhan Hadi, Kafi Mohammad Nasir Al Asadi

23. Helicobacter Pylori-Associated Iron-Deficiency Anemia and Interleukins Effect 125
AthraaRazaq Mohammed Hindi, Oday MitibHadi

24. The Influences of Antenatal Care, Postnatal Care and Early Initiation of Breastfeeding on an Exclusive Breastfeeding Pattern in the Working Area of Manukan Kulon Public Health Center at Surabaya City 129
Azizi Pridasari, Lutfi Agus Salim

25. Medico-Legal Updates of the Adverse Threat of Cigarette Advertisements on Children 135
Bambang Eko Turisno, IGA Gangga Santi Dewi, Suharto, Ery Agus Priyono

26. Term Lowbirth Weight Neonate: Maternal Factors 140
Bashar Mukhlif Khalaf, Zuhair Idreas Mohammed, Nada Hasan Ali

27. Detection of Heavy Elements and Pathogenic Microorganisms in the Water and Sediments of Domestic Water Tanks in the Center of AL-Nasiriyah 147
Basim Y. Al-khafaji, Hassan Abd Ali Namaa

28. Appraisal the Quality of Drinking Tap Water in Different Regions of Kirkuk City.....152
Batool Kh. Mohammad, Kameran Sh. Husien, Israa Zainal

29. Strategies Adopted by Women of Rural and Urban Areas for Weight Losspost-Pregnancy.....161
Blessy Mohandass, Amanpreet Kaur; Timsy; Nitika Choudhary, Shivani Rana, Sonaly Robinson

30. Assess the Knowledge, Practice and Attitude Regarding Nosocomial Infections and their Preventive among Health Care Staff.....168
Blessy Mohandass, Amanpreet Kaur, Timsy, Harmeet Kour, Navneet Kaur, Pema Choden, Aishwarya Thakur

31. Oncology Research Productivity of Iraqi Authors: A Bibliometric Analysis During 1955–2019.....174
Bushra H Shnawa, Shireen M Al-Majmaie

32. A Study to Assess the Nursing Students Experience Regarding Online Classes During Covid-19 Lock Down Periods in SRM College of Nursing, Kattankulathur, Kancheepuram District-603203, Tamil Nadu, India.....183
C. Kanniammal, T. Suseelal, P. Malarvizhi, P. Vijay Daniel Raj

33. Study of Anxiety Levels among Occupational Therapy Students During Various Academic Assessments.....187
Chirag Pincha, A.V. Anuja, A. Sangeetha, M. Karthika, Samuel Sundar Doss

34. Plasma CD4 Count and Duration ARV as a Predictor of Virological Failure Amongst AIDS Patients.....192
Choirina Windradi, Erwin Astha Triyono, Musofa Rusli

35. Physiotherapy Students Willingness to Report Misconduct to Protect the Patient's Interests in Chennai 198
D. Malarvizhi, Bhagya Lakshmi K., Hariharan S.

36. Effect of Phase 1 Cardiac Rehabilitation to Non-Invasive Hemodynamics in Acute Myocardial Infarction Patients.....202
Desi Natalia Trijayanti Idris, Dian Taviyanda, Srinalesti Mahanani

37. Awareness among MBBS Students About Rise of Violence Against Doctors.....211
Divya Reddy Pannala, S.M. Krishna Sagar, Hemantha Rao Amara, Harshini Deshapathi

38. Study of Production and Characterization of Laccase Enzyme from Klebsiellapneumoniae K7 Isolate 216
Doaa Khalid Mezaal, Essam Fadel Al-Jumaili, Ahmed Majeed Al-Shammari

39. Transformation of the Social Insurance Management Agency on Health.....223
Endang Sulistyaningsih, Hartiwiningsih, Is Haryanto

40. Bio-Nanocomposites: Parepartion Technology and Applications.....228
Fadhil K. Farhan, Nura Anwer Abdulzahara, Muhammad AL-Jobori

41. Knowledge and Attitudes of Vaccination among Iraqi Pharmacy Students.....235
Fadia Thamir Ahmed

42. Trend of Implementation Foster Family Toddlers (FFT) Programin East Java Province at 2015-2019.....242
Fadilatul Fahmiyah, Lutfi Agus Salim

43. Assessment Knowledge of the Patients' with Acute Renal Failure Concerning Dietary Pattern in Dialysis Unite of AL-Zahraa Teaching Hospital at AL-Kut City.....249
Faisal Younus Sameen, Qassim Jawell Odah Abed, Tareq Al-Qassab, Ashwaq Yas Khudhair

44. Assessment of Women's Knowledge and Practices toward Family Planning at Maternity Hospitals in Baghdad City 253
Fatima Fadel Benyian

45. Regulation of Law Enforcement in Prevention and Handling of Fire Forests in Environmental Hazards 259
Fatma Ulfatun Najicha, **I Gusti Ayu Ketut Rachmi Handayani***, Lego Karjoko*

46. Study on Effectiveness of Staff Welfare Program Regarding Occupational Stress During COVID 19 Pandemic among Nursing Officers.....263
Franny Joel Emmanuel, Yugmi Vala, Tapan Dodia

47. Nomophobia: An Assessment of No Phone Phobia among Adolescents.....269
Gaurav Kohli, Manu Kohli, Poonam Joshi

48. Production of Bioemulsifiers from Bacteria Grown on Hydrocarbons 275
Ghassan M. Ahmed

49. Prevalence of Head Lice ***(Pediculus humanus capitis)*** among Primary School Children in Baghdad Suburbs .280
Hadeel T. Al-Barrak

50. Estimating the Concentration of Lead and Cadmium for Some Areas of Najaf Governorate 285
Hakeem J. I.

51. Socio-demographic Predictors of Perceived Health among Syrian Refugees in Jordan.....287
Hamza Alduraidi, Zyad Saleh, Ayman Hamdan-Mansour

52. Predictors of Psychosocial Burden among Workers During the COVID-19 Pandemic Period in Indonesia 292
Hario Megatsari, Agung Dwi Laksono, Mursyidul Ibad, Yeni Tri Herwanto, Kinanty Putri Sarweni, Rachmad Ardiansyah Pua Geno, Estiningtyas Nugraheni

53. Relationship of Family Support with Anxiety Levels in Preschool Children Hospitalized in Pediatric Ward Syech Yusuf Hospital Gowa Regency, Indonesia.....298
Hartati, St. Aminah, Muh. Yusuf M.

54. The Effect of Qourum Sensing genes (***lasI, rhlI***) in Some Virulence Factors of ***Pseudomonas aeruginosa*** Isolated from Different Clinical Sources.....303
Hasan Falah Lahij, Abdulla H. Alkhater, Muthanna Hamid Hassan, Luma Amer Yassir

55. Total Matrix Metalloproteinase-2 and Prostaglandin E2 as Potential Biomarkers in Iraqi AML Patients 309
Hassnien S. AL- Hashemi, Sabah A. Hameid A. Rahman, Zeyad A. Shabeeb

56. Molecular Profile of Integrase gene ***intI*** and Carbapenem gene in ***Aeromonas sobria*** Isolates.....316
Hawraa Natiq Kabroot AL-Fatlawy, Taghreed Abdul Al-Kareem Al-Makhzoomy, Mohammed Abdulaali Al-Hakeem

57. Comparative Study of Children with/without Iron Deficiency Anemia Based on Parents' Knowledge, Attitude and Practice in Basra/Al-Madinah City.....321
Haydar Mohsin Abdulhussein, Jabbar Taresh Ahmed, Abbas Ali AL-Kinani, Faiz hussien ali, Rasha Mohammed Jumaah

58. Effect of Allogenic Omental Graft on Esophegotomy Incision in Dogs Models.....328
Hayder Hussein Abd, Montaser Mohammede Hellal, Ammar Maatoq Hashim

59. The ***ITGB3*** Genevariant among Sample of Glanzmannthrombasthenia Iraqi Patients 333
Hayderkareemkataa AL-Aidy, Ehab Dawood Salman, Safa A Faraj, Zaid Jamal Mahmood

60. The Role of P53 Serine 46, Burkitt Cell Lymphoma 2 (BCL-2), and Cysteinyl Aspartate Specific Proteinase 3 (Caspase 3) Proteins as Risk Factors in Abortion 340
Herlambang Herlambang, Firman F. Wirakusumah, Jusuf S. Effendi, Ida Parwati, Leri Septiani, Ahmad Faried, Hiroyuki Kuwano

61. Healthy Home Concept According to Javanese Ethnic Panaragan Society: An Etnolinguistic Study 346
Hujaefa Hi Muhamad, Titi Rapini, Sri Sugiharti, Alip Sugianto, Siska Diana Sari

62. Strengthen the Authoritative Function of the Regional Representative Councils in Legislation.....351
I Gusti Bagus Suryawan

63. Knowledge, Attitude and Quality of Life among Type 2 Diabetic Patients in Palestine 355
Imad Thultheen, Ayman M. Hamdan Mansour, Ward Zandeeq, Maysam Ewesat, Saleem Razek, Diana Jabareen

64. Education as Predictor of Low Birth Weight among Female Worker in Indonesia.....360
Ina Kusrini, Noviati Fuada, Sri Supadmi, Agung Dwi Laksono

65. Dental Care Interventions as Efforts to Reduce PUFA Index and Improve Nutritional Status in Children aged 9-12 Years in Orphanages.....366
Indrayati Fadjeri, Rahaju Budiarti, Tedi Purnama

66. Psychological and Personality Development Supports to the Prisoners in Correctional Institution in Indonesia 372
Irma Cahyaningtyas, Nur Rochaeti

67. Dispute Resolution through Mediation in Endowments Cases in the Legal Effectiveness Theoretical Perspective .. 376
Islamiyati, Rofah Setyowati, Dewi Hendrawati, Aisyah Ayu Musyafah, Ahmad Rofiq

68. An Observational Study to Compare the Effect of Two Different Doses of Dexmedetomidine on Hemodynamic Response to Laryngoscopy and Endotracheal Intubation.....381
Jatin B. Patel, Riddhi Agrawal, Malini Mehta

69. Favipiravir, will it be the Answer for the Specific Management of COVID-19?: A Review 389
Jayant Patharkar, Maulin Mehta, Janhavi Patharkar

70. Glycemic Control of Non-Hodgkin Lymphoma (NHL) Non-Diabetes Mellitus (DM) Patient in the First CHOP Chemotherapy.....393
Jualita Heidy Saputri, Hermina Novida, Ami Ashariati

71. Reformulation of Medical Rehabilitation against Victims of Narcotics Abuse in Indonesia 401
Jumriani Nawawi, Slamet Sampurno, M. Syukri Akub, Nur Azisa

72. Impact of COVID-19 Pandemic and National Lockdown on Mental Health among General Urban Indian Population: An Online based Cross-Sectional Survey.....406
Jyoti Sharma, Irshad Ahmad, Shahin Naz Jamali, Yamini Sharma, Megha Yadav, Sakhshi Arora, Mangalam Kumari

73. Information Disclosure and Control on Online Social Network Sites among Medical Undergraduates 414
K. Sudha, Sangeetha A., Kumaresan M., Paarthasarathy B.

74. Factors Related to Deaths Due to Suicides in Females Aged 12-24 Years 417
Kandagatla Krishnamurthy, Shruthi Reddy Jillella, Abhijith Subedhar

75. Method of Ventral Hernia Repair: Our Experience 422
Ketul Shah, Ankur Jain, Vipul Gurjar, Anant Shah

76. Molecular Characterization of Sewage Bacteriophage and Their Efficiency in Treatment of Antibiotic Resistant Bacteria 427
Khalid Ibrahim Mahmood, Ahmed Mohammed Turki

77. Assessment of Awareness on COVID-19 among Adults by Using an Online Platform: 26 Countries View 434
Kogila Palanimuthu, Birhanu Gutu, Leta Tesfaye, BuliYohannis Tasisa, Yoseph Shiferaw Belayneh, Melkamu Tamiru, Desalegn Shiferaw

78. Assessment of Stress, Fear, Anxiety and Depression on COVID-19 Outbreak among Adults in South-Western Ethiopia 440
Kogila Palanimuthu, Hamba Yigazu, Eshetu Fikadu, Gemechu Gelalcha, Yirgalem Bekele, Getachew Birhanu, Birhanu Gutu

79. Prevalence of Overweight and Obesity among School Going Adolescent in Patna 446
Kumari Mangalam, Chauhan Muneesh, Anand Akshay, Fatima Ambreen, Saho Pramod

80. Relationship between Coronavirus (COVID-19) and Social Factors: Evidence from 24 Countries Over the World During 88-Day Period from Jan 31 to April 27, 2020 451
Lien Nguyen-Phuong, Hang Thu Thi Dang, Nhung Phuong Thi Nguyen

81. Satisfaction and Complaints of Patients with Removable Partial Dentures: In Sample at Baghdad City, Iraq 456
Luma Musa Ibrahim

82. Deep Learning Classification Method to Detect and Diagnose the Cancer Regions in Oral MRI Images 462
M. Praveena Kirubabai, G. Arumugam

83. Chalk and Talk Versus Powerpoint: Perception among Medical Students 469
Mahanta Putul, Lahkar Babita, Borah Pollov, Das D.K., Choudhury Manoj Kumar

84. ***In-vitro*** Cytotoxic Activity of E. ***coli*** Outer Membrane Vesicles (OMVs) Against Breast Cancer (MCF-7) Cell Line 474
Mahmood Abed Hamzah, Ali Husain Alwan, Suzan Saadi Hussain

85. The Predictive Value of Serum Progesterone and Estrogen Recepters as Diagnostic Tool for Premature Ovarian Failure 481
Mahmood Khalil Ibraheem, Mutazsabahahmied, Firas Shawqi Algburi, Amina Hamed Alobaidi

86. The Predictive Value of Osteocalcin, Granulin, Cathepsin K and Some Other Biomarkers in Women with Premature Ovarian Failure 486
Mahmood Khalil Ibraheem, Mutazsabahahmied, Firas Shawqi Algburi, Amina Hamed Alobaidi

87. Relation of Human Papilloma Virus Infection with Pre Malignant and Malignant Endometrial Lesions 490
Mahmoud Mohammed Mahmoud, Aseel Ghazi Rifat

88. Differences between Bribery and Gratification: A Review of Anti-Corruption Act of Indonesia 497
Mahrus Ali, Al Halim, WahyuPriyanka Nata Permana

89. Study to Assess the Level of Stress among Nursing Students 503
Mandeep Kaur, Kanika Guleria, Anisha

90. Methodical Learning on Organ Donation: Effect on Students Knowledge and Attitude 508
Maninder Singh, Manpreet Kaur Grewal, Amanpreet Kaur, Yamini Chopra, Aarti Bhatt, Tenzin Choden, Manisha Sharma

91. Variation in Sleep Pattern Due to Lockdown among Collegiate Students 513
Manisha Bhandari, Rabab Kaur

92. Patient's Knowledge and Satisfaction with health Care of a Tertiary Care Hospital Situated in Rural area of Northern India (Haryana) 520
Manisha Rani, Jyoti Phougat, Manpreet Kaur

93. Stress in Working Women Due to Lockdown: A Cross Sectional Survey 527
Manjeet Singh, Rabab Kaur

94. Integration of Health Education and Cultural Value of Bimanesse Called "Maja Labo Dahu" toward the Intention to Stop Smoking of Smoker Student at Bima District-Indonesia 532
Martiningsih, Nurul Inayati, Rini Hendari, Ade Wulandari

95. Application of Poskestren as Health Promotion Strategy for Improving Clean and Healthy Behavior of Pesantren in East Java Province 537
Maygi Restu Yang Esa, Muhammad Baharuddin Wisudawan Putra, Diyah Werdiningtyas, S.Gz

96. Perception of Successful Aging in Nursing Students 543
Mihyeon Seong

97. Inhibition Activity of Water Hyacinth Leaf Extract (Eichornia Crassipes) to the Growth of Subgingival Plaque Bacteria Colony 552
Ayu Arismawati, Noer Ulfah, Lambang Bargowo

98. Study to Compare Progrip Mesh vs Conventional Mesh in Lichtenstein's Open Inguinal Hernia Repair 557
Mohammad Farooque Dudhwala, Chiraag Hiran S., Vipul Gurjar, Honeypalsinh H. Maharaul, Vipul Shory

99. TMEM121 Protein Is a RegulatIon Factor in the Proliferation Activity of the Adrenocortical stem/Progenitor Cells 562
Mohammed Abdalmalek Ali Al-Bedhawi

100. Impact of Broken Family upon Adolescents' Behavior at Secondary Schools in AL- Najaf AL-Ashraf City.....568
Mohammed Baqer Hassan, Khetam Mutashar Hatab

101. The Safety and Efficacy of Sacral Neuromodulation on Refractory Urgency Urinary and Fecal Incontinence in Iraqi Patients 575
Mohammed Bassil Ismail, Wameedh Qays Abdullhussein

102. Glycodeline-A, sFlt-1, PlGF Combined as Predictor Markers of First Trimester Pregnancy Loss in Iraqi Women.. 580
Mohammed H. Dawood, Halla G. Mahmood, Afraa M. Nedawi

103. The Effect of Using Panicum Mombasa Hay and Millet Hay in the diet on the Production Performance of Awassi Lambs 587
Mohammed H . Fannos, Husam H. Nafea, Ahmed A. Al-Ani

104. Effect of Combined Antibiotics and Biofilm Formation in Some Bacterial Pathogens from Otitis Media among Children in Baghdad, Iraq 592
Mohammed Khudhair Alwan, Kais Kassim Ghaima, Zainab Shaban Khalaf

105. The Role of Religion and Spirituality in Alcohol Use Treatment and Recovery: An Integrative Review 599
Mohannad A. Aldiqs, Ayman M. Hamdan-Mansour

106. Quality of Life After Bariatric Surgery 606
Moly K.T.

107. Socio-Legal Updates of Children's Rights on the Protection and Shared Assets in Divorce Cases in Indonesian Family Law.....613
Muhyidin

108. New Treatment for Regular Astigmatism Using Physical Exercises 618
Mundher Sameen Shuker

109. Patterns of Paediatric Maxillofacial Fractures: A Twelve-Year Retrospective Study 624
Musaev Shamshodbek Shuxratovich, Shomurodov Kahramon Erkinovich, Abduxalikov Sirojiddin Faxriddin O'g'li, Narzieva Mahliyo Isrofil Qizi

110. Effect of Blood Groups and Complications on Orofacial Measurements of B Thalassemia Adult Patients.....627
Nada Hashim Mohammed, Nawal Mustafa Abdullah, Riad Altaee

111. Prevalence of Oral Maxillary and Mandibular Tori among Outpatients Attending Dental Collage in Basra Governorate Southern of Iraq.....635
Nadia Azzam Al-Shareeda, Majed Mohamed Refaat, Abdullah M. Hussain

112. Appraisal of Genotoxicity and Cytotoxicity of Depakine® and/or Epanutin® in Bone Marrow Erythrocytes and Hepatocytes of Male Albino Mice by Comet and Micronucleus Assays.....638
Nagla Zaky Ibrahim El -Alfy, Amany Ibrahim Alqosaibi, Mahmoud Fathy Mahmoud, Ayman Mohammad Abdullah

113. Assessment of Neutrophil-to-Lymphocyte Ratio, Platelet-to-Lymphocyte Ratio,Oxidative Stress and Anti Oxidants levels in Polycystic Ovary Syndrome Patients with Low-Grade Chronic Inflammation 644
Najlaa Abdulameer Ali AL-Dahhan, Aseel Jassim Albdairi, Ammar Jabbar Hamad

114. Impact of Breakfast Habits on Physical Parameters and Academic Performance of Nursing Students 653
Nalini M., Sukesh, Joyce Fernandes

115. Self Medication Practices among Youngsters: A Global Health Concern.....658
Navdeep Kaur, Bandana Bisht, Manmeet Kaur

116. Service Quality Assessment of Higher Education by Gray Approach (The Case of Kerbala University) 664
Nawal Mousa Almeyali, Ali Al Mousawi

117. Effectiveness of Breathing as a Non-Pharmacological Method to Reduce Pain Severity among Woman During Labor.....674
Nawras Monim Alzurfi, Shukriyia Shadhan Al-Ogaili

118. Vitik Detection of Aerobic Spore-Forming Bacteria Isolated from Raw Milk, Skim Milk Powder and UHT Milk.. 678
Nawres N. Jaber, Nada Salih Hadi, Abeer Laily Mohammed, Marwa Idan, Adyan Niama

119. Counseling with Tooth Brushing Demonstration Method as an Effort to Improve Tooth Brushing Skills and the Status of Dental and Oral Hygiene in Early Childhood at School 684
Ngatemi, Tedi Purnama

120. Smoking Behavior among Female Worker in Indonesia Does Education Matter?.....688
Nikmatur Rohmah, Anita Dewi Prahastuti Sujoso, Masruroh, Ilyas Ibrahim, Qurnia Andayani, Irfansyah Baharuddin Pakki, Agung Dwi Laksono

121. Biostatistics Evaluation of Women Breast Lesions in Baghdad/Iraq.....694
Noor F.M. Ali, Hiba A. Abdul Sattar, Mervet Abd-alhassan, Fathaa Abdullah Mahmoud, Munya H. Sabri

122. Strategies of Carious Tissue Removal in Deep Carious Lesions among Dentists in Iraq: Online Based Survey Study.....698
Noor H. Fadhil, Anas F. Mahdee, Ahmed H. Ali

123. Antibiofilm Activity of Nystatin, Aspirin and EDTA Against ***Candida albicans*** Isolated from Iraqi Women with Vulvovaginitis 703
*Noor Naser Raheem, Kais Kassim Ghaima**

124. Radiographic Evaluation of Five Variables in Iraqi Young Subjects among Impacted and Erupted Lower Wisdom Teeth Groups 712
Nuhad A. Hassan, Amal R.S. Mohammed

125. Information Seeking Problems that May Occur Against Covid-19 Vacccine When it is Ready.....718
Olowo Emmanuel Opeyemi, Hamisah Hasan, Abdul Mua'ti, Julia Wirza Mohd Zawawi

126. Newly Emerged Online Educational Framework in Nursing Major During the Pandemic of COVID-19.....722
Omar M. Khraisat, Ahmad M. Al-Bashaireh, Mohammad O. Khraisat, Fatima H. Khraisat, HD، Eman Nazly, PhD, RN، Mohannad A. Aldiqs, MSN, RN

127. Factors Contributing to Emotional Distress among Postpartum Mothers with Newborns at Newborn Unit Kenyatta National Hospital, Kenya 728
Omulo O. Wycliffe, Cheptum Jebet Joyce, Mageto G. Irene Mageto

128. Assessment of Satisfaction Level and Quality of Life among Haemodialysis Patient's on Dialysis Therapy 734
Parimala L., Mary Sofia

129. Exogenous Cushing's Syndrome with Subsequent Secondary Adrenal Insufficiency in Patients with Long Term Steroid Usage.....738
Cynthia Ayu Permatasari, Ferdy Royland Marpaung

130. Influence of Exercise Classics on the Ability to Switch the Attention of Schoolchildren Aged 9-10 Years.....744
Polevoy G.G.

131. Effectiveness of Teaching and Text Message Based Intervention on Dietary Habits among Overweight Adolescents in Selected Schools of Ambala, Haryana 749
Pooja, Kanika, Srinivasan P.

132. Changing Trends Inpoisoningat a Tertiary Healthcare Centrein North Karnataka, India.....755
Pratibha R. Kulkarni, Ranganath R. Kulkarni, R.B. Kotabagi

133. Approach to Patients with Hemorrohoids at Our Teritary Care Centre 760
Pratik Shaparia, Brijesh Bharodiya, Vipul Gurjar, Honeypalsinh H. Maharaul

134. Behaviours (Cognitive, Affective and Psychomotor) among Patients with Gout Arthritis in Elderly.....763
Chilyatiz Zahroh, Asmaul Faujiyah, Ima Nadatien, Yasi Anggasari, Nur Ainiyah, Siti Nurjanah

135. Clinical Study of Functional Outcome of External Fixator Device as a Primary Definitve Treatment of Open Tibia Fracture.....768
Praveen Garg, Rajvirsinh Sodha, Fahad Bin Hamid, T. Somashekarappa

136. To Study Preloading and Relative Efficacy of Ringer's Lactate and Pentastarch 6% Prior to Spinal Anaesthesia in Lower Abdominal and Lower Limb Surgeries.....772
Priya Kishnani, Ishaan Batra, Tejash Sharma, Malini Mehta

137. Human Liver Morphology: Anatomical Study about the External Aspects.....780
Priyanka N. Sharma, Nirali Chavda, Hetal V. Vaishnani, K.M. Parmar, Kinjal Jethva, Manoj Kulkarni, A.R. Gandotra

138. Informed Consent to Patients in Root Canal Treatment (Case Study: Melati Dental Clinic Jakarta, Indonesia) .786
Pudentiana Rr RE, Tedi Purnama, Syifa Yulia Lestari, Yulianti

139. Assess Knowledge and Attitudes on First-Aid Measures for Selected Domestic Accidents among Caretakers of Under-Five Children.....790
Pushplata Manta, Kanu Mahajan, Kanika Guleria

140. Anthropometric Assessment of Canthal Distances and Canthal Index of South Indian Region: A Cross-Sectional Study.....794
Radha K., Srinivasan K.R.

141. Tuberculosis of the Breast: A Challenging Component of Benign Breast Diseases.....798
Rajbangshi M.C., Deka Sumi, Mahanta Bandana, Mahanta Putul

142. Iron Content as an Indicator for ***Legionella*** Species in Artificial Water Systems 803
Rajeshwari Vittal, Juliet Roshini Mohan Raj, Ballamoole Krishna Kumar, Indrani Karunasagar

143. Deleted

144. Practice of Documentation at Casualty of Tertiary Care Hospital: An Interventional Study 816
Ramasamy R., Ganesh Rajendiran, Kagne R.N.

145. Risk Factors for Neonatal Death in Female Workers Mothers in Indonesia.....822
Ratna Dwi Wulandari, Agung Dwi Laksono, Astridya Paramita, Pramita Andarwati, Naillul Izza

146. Barriers to Antenatal Care Utilization in Indonesia 828
Ratna Dwi Wulandari, Agung Dwi Laksono, Tety Rachmawati, Rukmini Rukmini

147. A Questionnaire Based Study Evaluating Awareness for Organ and Body Donation and Cadaveric Dissection among the General Population Attending Medical and Dental Hospital 835
K.M. Parmar, Hetal Vaisnani, Nirali Chavda, Priyanka Sharma, Kinjal Jethava

148. Assessment of Scapula Muscle Strength in Housemaids 840
Riddhi Shroff, Ankita Jain

149. Effectiveness of Piriformis Stretching and Intermittent Lumbar Traction along with Spinal Extension Exercises in Lumbar Disc Herniation: Comparative Study 844
Rituraj Verma, Taruna Verma, Vikas Sharma, Yash Pratap, Sanghamitra Jena, Sajjad Alam

150. Cassava Leaves Extract ***(Manihot esculenta***) Prevents the Decrease of Albumin Serum Level in Mice with Gentamicin-Induced Hepatotoxicity 848
Rosita Dewi, Rena Normasari

151. Common Warts Treatment by Intralesional (60,000 Versus 120,000) IU of Vitamin D3, Comparative Study ... 853
Ruya Thamer Ihsan Mahmoud, Mazin Hamid Ayyash

152. Using of Glycated Albumin Rather than Glycated Hemoglobin for assessing Glycaemic Control in Hemodialysis Patients with Type II Diabetes Mellitus 860
Salahaldin M. Fahad, Rashied M. Rashied, Waleed N. Jaffal

153. Pattern of Head Injuries in Deaths Due to Two-Wheeler Road Traffic Accidents 866
S.M. Krishna Sagar, Divya Reddy Pannala, K.V. Ramanamurthy, K. Rajender Kumar

154. Maxillofacial Trauma and Alcohol Abuse: A Descriptive Cross Sectional Study 871
S. Devakumari, T. Vijhayapriya, Nandini Biradar, P. Amudha, D.S. Dinesh, S. Devameena

155. Histopathological Grading and Enzyme Histochemical Study of the Placenta in Gestational Diabetes Mellitus Pregnant Women 878
Sahar A.H. AL-Sharqi, Amal Kadhem Chaloob, Ilham Abd Allah Ali Al-Saleem

156. Subjective Assessment of Satisfaction Degree and Psychosocial Status of Patients with Highly Atrophic Mandible Treated by Implant-retained Over-denture 886
Salah A. Al Omoush, Wijdan R. El Manaseer, Firas Al Soleihat, Kifah D Jamani

157. Valuable Dental Materials from Salvadora Persica Plants 893
Salah A. Jassim, Kafa K. Hammud, Bassam Alsheekhly

158. Serological Tests Assessment in Patients Suspected to have Celiac Disease Attending the Gastroenterology and Hepatology Teaching Hospital in Baghdad 904
Samer Nema Yassen Alkemawy, Shymaa Nema Hamed Alsaltani

159. Evaluating the Sensitivity of (miR-378) as a Circulatory Screening Biomarker for Diabetic Cardiomyopathy: Comparative Study 912
Sana Abdul-Jabbar Ali, Hyder Hashim Al-Shlah, Mais Mazin Al-Hamdani, Oday Jasim Al-salihi

160. Using the Digital Occlusal Analysis (T-Scan NOVUS) in Diagnosis the MFDS in Iraqi Patients During Lateral Excursion Movements 919
Sanaa Abdul Hameed Hussein, Jamal N. Ahmed

161. Awareness on Nutritional Anemia and its Prevention among Adolescent Girls 925
Santhi P., G. Ambujam

162. Incidence and Predictors of Postoperative Acute Kidney Injury in Non-Cardiac Surgery 930
Sara Mary Thomas, Bhavika Sangada, Sanam Vasava, Lokesh Akkineni, Chaitri Shah

163. Gender Differences in Life Satisfaction: The Moderation Role of Social Support among Older Persons 935
Sarah Al-ja'freh, Rabia Allari, Ayman M. Hamdan-Mansour

164. Effects of Emotional Intelligence on Multi-cultural Cognition and Multi-cultural Attitude in Undergraduate Nursing Students in Korea.....941
Seong Mihyeon, Chung Soojin, Hong Hyonjoo, Song Jihyun, Hwang Wonju

165. Characteristic of CD4+CD25+ T Cells in Chronic Myeloid Leukemia Patients Treated with Imatinib Mesylate with Different BCR-ABL Transcripts Levels Response 949
Shahla'a Fadhil Sabir, Wifaq Mahmood Ali Alwatar, Bassam Francis Matti

166. Effect of Segmented Sleeping on the Academic Performance of Medical Students. A Questionnaire Survey 956
Shalini S.P., Balaji K., Yuvaraj Maria Francis, Gunapriya Raghunath, Vijayalakshmi S.

167. Study ***ndvB*** gene Expression in ***Pseudomonas aeruginosa*** Producing Biofilm.....961
Shamam Tahseen Ismail, Mohammed Ibraheem Nader Altaai

168. Prevalence of Child Physical Abuse among School Children in Mosul City\North of Iraq 966
Shatha Abdul-Rahman H. Al-Ghurairi, Eman Al- Khafaf, Hana A. Al seed

169. Quintessential Conceptualization of Bone Graft 973
Shipra Jaiswal, Amit Wadhawan, Mehvish Saleem

170. Role of Mental Health in Understanding and Preventing Suicide.....979
Smita Satapathy, Madhubrata Mohanty

171. Awareness of Adverse Effects of Lead-containing Cosmetics among the Adolescence and Young Adult Population in Chennai: A Survey 984
Sneha A., Balaji K., Yuvaraj Maria Francis, Gunapriya Raghunath

172. Medical and Legal Constraints for Organizing 2020 Regional Head Election in the Covid-19 Pandemic in Indonesia.....990
Sri Wahyu Ananingsih, Ratna Dewi Pettalolo

173. Correlation between Disability and Stigma on Leprosy Patient at General Public Hospital of Daha Husada Kediri 995
Srinalesti Mahanani, Desi Natalia Trijayanti Idris

174. Recurrence Rate of Surgical Resection with Reconstruction of Plate Osteosynthesis in the Ameloblastoma Treatment.....1000
Suha Mohammad Sami

175. Older People with Urinary Incontinence: A Nurse Practitioner' Role in the Assessment and Management 1006
Supichaya Wangpitipanit

176. Infliximab-Associated Hepatic Injury in Crohn's Disease 1012
Sura A. Abdulsattar, Raghd A.Y. Alkhader, Haider Ridha Mohammed Saeed, Fatin F. AlKazazz

177. COVID 19: Evaluate of Liver and Renal Function Tests in Iraqi Patients 1018
Sura A. Abdulsattar, Mahmood Nazar Mustafa, Abdullah Ali Mohammed, Ahmed Salam Al-zaidi

178. Implementation of Cross-Sectoral Collaboration in the Leptospirosis Control in Jeneponto Regency: A Qualitative Approach 1022
Syamsuar Manyullei, Muh. Fajaruddin Natsir, Wirdayanti

179. Impact of Quality of Healthcare Services on Consumer's Satisfaction at Primary Healthcare Centers 1029
Tariq Yassen Taha, Wissam Jabbar Qassim

180. **The Relationship between Adolescent Risk Behavior in Drug Abuse: *A Literature Review*.....*1037***
Ahmad Yani, Sukri Palutturi, Ridwan Amiruddin, Sudirman Nasir, Aminuddin Syam, Rajindra, Anto J. Hadi

181. The Effect of Environmental Factors on the Enzyme Production of ***Aeromonas Hydrophila*** Isolates.....1043
Hawraa Natiq Kabroot AL-Fatlawy

182. Sleep Patterns in Overweight/Obese Adults in Baghdad City 1051
Maha Sabah Ahmed Al-Jumaili

183. Analysis of Prothrombin Time (PT) and Activated Partial Thromboplastin Time (aPTT) in Patients with Acute Myocardial Infarction on Anticoagulation Therapy to Assess the Thrombogenic Potential 1058
Shubhi Saxena, Nishant Saxena, Richa Jain, Jasmin Jasani

184. Correlation of the Stature to Forearm Length in the Young Adults of Western Indian Population.....1062
Suryabhan S. Dongre, Ravindra B. Deokar, Sachin S. Patil

185. Assessment of Nursing Students' Knowledge toward Preventive Measures of Urinary Tract Infections in Mosul Teaching Hospitals 1070
Tahsein Muhsin Hussein, Munther Nather Al-Fattah, Tameem Thamir, Radhwan Hussein Ibrahim

186. Impact of Educational Program on Nurses' Knowledge toward Coronary Artery Bypass Graft Surgery in Mosul Teaching Hospitals 1075
Tahsein Muhsin Hussein, Myasar Mohsin Azeez, Radhwan Hussein Ibrahim

187. Quality of Health Care System and Structure at Primary Health Care in Baghdad City 1081
Tariq Yassen Taha, Wissam Jabbar Qassim

188. Relationship of IL-6 Level and Lipid Profile as Predictor Ventilator-Associated Pneumonia 1088
Taufiq Gemawan, Arie Utariani, Kuntaman

189. Saliva of Tobacco Smokers a Profile of C3, IgA, Amylase and Total Protein 1093
Zahraa Hussein M. Kadri, Hazima Mossa Alabassi, Ahlam Jassim Taher

190. Anti-Islet Cell Antibody and Anti-ovarian Antibody Levels in Iraqi Women with Polycystic Ovary Syndrome..... 1098
Zainab Ali Hlail, Ahmed Sahib Abd-ulamir, Khalil Ismail Abd-Mohammed, Mohammed Odah Salman

191. The Effect of Serum Estradiol Level at the Time of HCG Injection on the ICSE Outcome.....1102
Zainab Abd Alkathem Fatnan, Zainab Alkhafajy, Aseel Abdulameer Mohammed

192. The Satisfaction of Patient with Respect to the Aesthetic and Phonetic of Removable Partial Denture Therapy for Iraqi Patient.....1108
Zainab Mahmood Al-Jammali, Anas Al-Yasiry, Zahra S. Abed Karkosh, Azad Almuthaffer

193. The Accumulative Effect of Heavy Metals on Liver and Kidney Functions 1114
Zeyad Gattea Koshan Al-Rikabi, Montaha Abulkareem Al-Saffar, Adnan H. Abbas

Lecturer, Prof., Ministry of Science and Technology/Environment and Water Directorate/Baghdad, Iraq, Lecture, Department of community health,Medical technical Institute, Middle Technical University, Baghdad, Iraq

194. Assess the Knowledge of Married Women in Reproductive Age Group Regarding the Contraceptive Method 1120
Timsy, Amanpreet Kaur, Nirlep Kaur, Sandeep Kaur, Shiwani, Nikhil

195. An Analytical Prospective Study of Plasma Pseudo–Cholinesterase Level & its Co-Relation to Mortality in Acute Organo Phosphate Poisoning.....1124
Tejas J., Siva Kumar V., Shruthi K., Vishwanathan K.G.

196. Perception of Nursing Care among Patients at SRM General Hospital, Kattankulathur, Kancheepuram District 1130
Keerthana S., Deepika M., C. Kanniammal, Ushapriya Mathiazhakan

197. Spectrum of Clinical and Hematological Changes in Patients of Malaria: A Tertiary Care Hospital Experience in Gujarat 1134
Trupti R. Jansari, Jigna P. Patel, Amit Chauhan, Jasmin Jasani

198. Relationship of Knowledge and Attitudes with Male Participation in Vasectomy in Indonesia 1139
Tjahja Bintoro, Bhisma Murti, Endang Sutisna, Suwarto

199. Premarital Sex Behaviour of Adolescents in Makassar, Indonesia 1143
Theresia Limbong, Made Sukarta

200. Health Literacy Associated with Raw Cyprinoid Fish Consumption in Northeastern Thailand.....1149
Tiwakron Prachaiboon, Pannee Banchonhattakit, Nathkapach Kaewpitoon Rattanapitoon, Surachai Phimha

201. Nutrient and Cost Optimization in Menu Planning at an Apex Tertiary Care Hospital Using Operational Research Techniques.....1155
Vijay Kumar Tadia, Mahesh R., Sidhartha Satpathy

202. Picture Archiving and Communication Systems (PACS): A Pre-Post Comparative Analysis.....1162
Vijay Kumar Tadia

203. Medico Legal Documentation in a Public Hospital in India: An Analysis of 100 Cases.....1168
Vijay Kumar Tadia, Paresh Shekhar Jangale

204. Evaluation of Radiology Information Systems including PACS at Two Tertiary Hospitals in India from User's Perspective.....1171
Vijay Kumar Tadia

205. Spinal Region Segmentation for Intervertebral Distance of X-Ray Images Using Spectral Analysis.....1178
Virendra Singh, **Vineeta Saxena Nigam**

206. Assessment of the Knowledge and Attitude Regarding Plastic Use and its Health Effects among Nursing Students of Selected Nursing Colleges of Ambala, Haryana.....1186
Vijyeta Bhasin, Shalini, Kirandeep Kaur Dhaliwal, Anamika Gautam

207. Socio-Demographic Profile of Suicidal Cases Autopsied at Tertiary Care Centre in Uttarakhand: A Retrospective Study.....1191
Vikas Vaibhav, Pawan Kumar Shukla, Sanchit Jain, Raviprakash Meshram

208. Study of the Balance System between Some Enzymatic and Non-enzymatic Antioxidants in Blood Serum of Patients with Rheumatoid Arthritis in Mosul City, Iraq.....1197
Walaa A. Al-Jawadi Muna H. Jankeer

209. The Concentration of Lead and Cadmium in the Gill and Muscle of Common Carp Fish (***Cyprinus carpio)*** in Three Fish Farms in DhiQar City–South Iraq.....1202
Wesan Fadhel Khalef, Zainab Mohsen Ibrahim, Bushra Ali Ghyadh

210. Characteristics, Effective Reproduction Number (Rt), and Prediction SIR Model of Covid-19 at Banyumas District, Central Java, Indonesia.....1206
Yudhi Wibowo, Nendyah Roestijawati, Siti Munfiah, Sadiyanto, Arif Burhanudin, Misti Rahayu

211. Medico-Legal Outlooks in Preventing Traffic Violations and Accidents by Enforcing the Structure and Function of the Police Unit 1213
Yusriyadi

212. Knowledge and Practice of Pregnant Iraqi Women about COVID-19 Preventive Measures 1217
Thikra N. Abdulla, Weqar Akram, Taghreed MardanAbullah

213. The Study Effects of ***Quercus infectoria*** on the Oral Environment in Gingivitis Patients.....1224
Ali Hasanain Alhamadani, Rana Talib Al-Muswie, Sameerah Jameel Tarfa

214. Relations between Interlukin-6 and Some Biochemical Parameters in Diabetic Foot Syndrome 1230
Raid M.H. Al-Salih, Zeena M. Ali

215. Prevalence of Work from Home on Female-it Workers, on Neck Pain and its Psycho-Social Effects During Epidemic Period 1240
Taruna Verma, Rituraj Verma, Diksha Bameta, Vikas Sharma, Sonia Saroha, Ashu Taneja

216. Comparison between the Classical Symphony and Self Selected Music on Muscle Endurance in Young Obese Males 1247
V. Mahammad Rafi, A. Sangeetha, Adlin K. Kazia, S. Prem Kumar, B. Arun Kumar, B. Vijayalakshmi

217. Factors Affecting Romantic Relationship Satisfaction of University Students.....1252
Kyu Eun Lee, Hae Kyung Chang

218. Non-Invasive Monitoring of Blood Glucose Concentration Based on Insulin Secretion Level Using NIR Spectroscopy for Diabetes Detection 1259
D. Arul Kumar, T. Jayanthy

219. Effects of Multidrug-Resistant Organism Infection Control Simulation Program on the Infection Control Fatigue, Job Stress, and Performance of Nurses 1267
Mi Hyang Lee

220. Assessment of Breast Cancer Risk by Gail Model in Women of Thi-Qar.....1273
Sara OmranIssa, Zainab H. Farhood, Zaman Subhi Madlool

221. ***In Silico*** Study Chitosan Snail Shell as Antioxidant Through Interesting NRF2-KEAP1 in Hypercholesterolemia. 1277
Umarudin, Dewi Ratih Tirto Sari, Fatchiyah Fatchiyah, Sri Rahayu, Sri Widyarti, Warsito

222. Synthesized Gold Nanoparticles Using ***Pseudomonas*** Supernatant and Study the Physical Characterization–Antproliferative Activity of Breast Cancer Cells (MCF-7).....1281
Karrar Nadhim, Nibras Nazar Mahmood, Aseel Mustafa

223. Molecular Detection of Tumor Necrosis Factor-Alpha (TNF- a) Gene in Mycotic aborted Placenta of Ewes Using RT-PCR 1287
Bushra Hamza Fares, Hameed Abdul Hussain Al-tememy, Ban Abbas Abdulmajeed, Mohammed M. Dakheel

224. Detection of ***Legionella pneumophila*** and ***Legionella dumoffii*** Biochemically in Water Samples in Baghdad City, Iraq.....1292
Jundi Alak Mahdi Al-Buhilal, Taghreed Khudhur Mohammed

225. The Relationship between Some Blood Components and Wool Production and Some of its Physical Traits in the Local Arabian Sheep 1297
Hafetd Musa Ali AL-Taee, Rahman Hussein Hamza Al-Qasimi, Azhar Abdulabbas Jaffar Shareef

226. Evaluating the Sensitivity of (miR-378) as a Circulatory Screening Biomarker for Diabetic Cardiomyopathy: Comparative Study 1301
Sana Abdul-Jabbar Ali, Hyder Hashim Al-Shlah, Mais Mazin Al-Hamdani, Oday Jasim Al-salihi

227. Effects of Duration of Diabetes and Diabetes Therapy (Metformin) on Fbxw7 Levels in Iraqi Type II Diabetic Patients.....1308
Suhayla K. Mohammed, Hayyan I. Al-Taweil, NouraKaram M. Salih, Samer Abdulhasan Muhi, Ekhlass M. Taha

228. Color Change of Two Different Nano-Hybrid Resin Composite Materials after Staining and Bleaching. (An ***in vitro*** Study) 1314
Zahraa Sabah Abdul Wahhab, Emad Farhan Alkhalidi

229. The Effect of Interfering Waves Strategy in Developing Some Basic Volleyball Skills for Intermediate First Graders.....1320
Aujeed Madlool Abbas, Sattar Jaber Ashour, Bashar Akram Mohammed, Jabbar Ali Kathim

230. Diagnostic Study of Some Microbiological Dacryocystitis with in Baghdad City Patients 1326
Zena K. Khalil, Ala'a K. Husain, Saif S. Al-Kamil

231. The Effect of the Physical and Artistic Education Lesson Through Play and Art in Developing Some Motor Abilities and Reducing Mobility for Pupils in the Fifth Grade of Primary School of the Primary Stage.....1332
Aujeed Madlool Abbas, Nawfal Shamkhi Naji, Haider Sami Muhammad, Jabbar Ali Kathim

232. Molecular Study of Genetic Diversity in ***Escherichia coli*** Isolated from Tap Water in Baquba 1338
Noor Jameel Allhaby, Hadi Rahman Rasheed Al-Taai

233. Asprosin Role for Obese Male Patients with Diabetic Mellitus Type II.....1345
Dina A.M. Al-Khafajy, Maysaa J. Majeed, Omar F. Al-Azzawi; Ayad Ismael Khaleel

234. The Effect of the Advanced Organizations 'Strategy on Attentional Control and Learning Some Offensive Skills Installed with Basketball for Students 1350
Ahmedkhalid Awad

235. The Effect of Rehabilitative Physical Exercises to Develop Some Aspects of Muscle Strength and Range of Motion in Rehabilitating the Deltoid Muscle of the Shoulder Joint of Badminton Players 1356
Mustafa Muhammad Ali Farhan, Salman Dawood Tuaimah

236. Human Folate Receptor-1 Gene Expression and Correlation with Physiological Leptin hormone in Obese and Non-obese Subjects.....1363
Areej GH Al-Charak, Hawraa H. Naji, Hamzah H. Kzar

237. EV Targeting MCF-7 Breast Cancer Cell Lines Inhibit Both mTOR and HIF-1A: Molecular Docking Study.1367
Haider O. Mossa Al-Gazali, Hamzah H. Kzar, Moshtak A. Wtwt, Moaed E. Al-Gazally

238. Road Traffic Accidents and the Traumatic Brain Injuries: A Cross- Sectional Study. 1374
Ali Abbas Hashim Al musawi, Hasan Alwan Baiee

239. Frequency of Left Ventricle Dysfunction in non-Alcoholic Fatty Liver Disease (NAFLD) Patients Detected by Global Longitudinal Strain and Tissue Doppler Imaging in Babylon Province in Iraq.....1380
Haitham Shaalan Sewan, Hassan Salim Aljumaily

240. Levels of Some Biomarkers in Ischemic Heart Disease Patients.....1387
Majida Sulaiman Aadai , Mayada Noori Iqbal, Nahlah Ghanim Abdul Majeed

241. Brain Hydatidosis Surgical Outcome 1395
Mohammed Z. Shaker, Nashwan Y. Sallama, Mohammed I. Ramadhan

242. Evaluation the Role of Malondialdehyde in Occurrence and Development of Diabetic Retinopathy Patients ..1400
Marwa Riyadh Khalaf, Mutaz Sabah Ahmeid, Osamah Jihad Abdulqader Hashim Abdulsattar Jabar

243. Psoriasis Beyond Local Skin Disease.....1409
Amina Hamed Ahmed Alobaidi, Abdulghani Mohamed Alsamarai, Muhib Ahmed Salih

244. IL-6, IL-0, IFN Gamma and CRP in Newly Diagnosed COVID 19 Patients 1418
Mazin Jabbar Kathim; Tamara Amer Taha, Suzan Saadi Hussain, Nihad Khalawe Tektook

245. The Value of Measurment of Bilirubin in Pleural Fluid in the Differentiation between Exudative and Transudative Pleual Effusion.....1423
Bint Al huda A. Jaber, Khalid Abd Alstar Hussein, Zahrah Salih

246. Serum Leptin Level and Thyroid Hormone in Type 2 Diabetes Patients.....1428
Hamza Mustaffa Khuder, Khudair Abbas Khudair, Ammar Lateef Hussein

247. Comparison between Using Bupivacaine 0.5% and Bupivacaine with Sodium Bicarbonate 8.4 % in Thoracic Epidural Anesthesia for Laparoscopic Cholecystectomy.....1435
Ayman G. Saeed, Khaled Ali Khaleel, Mohammed Asi Jabbar

248. Prevalence of Direct Peer Bullying among Primary Schools' Children in Holly Karbala Center.....1442
Ali Abdulrazzaq, Noor Fadhil Abass, Shaima' Nasir Mohammed

249. Types of Cancer Prevalence in Al Muthanna Province for Two Years' Duration (2018-2019).....1448
Sarah Ali Abed, Rana Dakhil Nafea, Suha Suhiel Hussein, Dergham Majeed Hameed, Ihab Abbas Taher

250. Histomorphometric and Histochemical Finding of the Proventicular and Ventricular Stomach between the African Grey Parrot (***Psittacus erithacus***) and Black Francolin (***francolinus***) in South Iraq 1457
Eyhab R.M. Al-Samawy, Shaima Khazaal Waad, Wissam Sajid Hashim Al-Uboody, Mustafa Salah Hasan

251. Salivary Sialic Acid Level and Oral Health Statues in Sample of Iraqi Children.....1466
Lamia I. Sood, Ameena Ryhan Diajil

252. Hypolipidemic and Antioxidant Efficacy of Apigenin in Hydrogen Peroxide induced Oxidative Stress in Adult Male Rats 1473
Mohammed I. Al-Rawi, Aous Kahtan Almzaien, Kahtan A. Almzaien

253. Detection of ***Propionibacterium*** in Samples by Metagenomic Analysis that Collected from Patients Suffering Acne Vulgaris in Babylon Province 1481
Rabab J H AL-Hasseny, Lamees A. Abdul-Lateef, Hussein Abbas AL-Sultany

254. Expression Levels of Efflux Pump ***mexR*** and ***norA*** Genes in Multi-Drug Resistant in Some Bacteria by Using Quantitative RT-PCR Under Stress of Effect Efflux Pump Inhibitors 1486
Baidaa Adel Ibrahim, Mayadaa Abdullah Shehan

255. Distinguish between Two Species of ***streptococcus*** by ***sk*** gene 1493
Rawaa Kh. Mohammed, Harith K. Buinya

256. Impact of Vitamin D Elements in Insulin Sensitivity in Type 2 Diabetes Mellitus (DM2).....1499
Wafaa Raji Alfatlawi, Zainab Majid Ali, Muhammed Abdul-Gabar Aldabagh

257. Angina and Sudden Fatal (Arrhythmia) Cardiac Disorders that affect People with the Presence of Risk Factors that Show a Change in the Electrical Conductivity of the ECG.....1505
Salah Abd-Al Kader Omran

258. Effectiveness of an Educational Program on Nurses' Knowledge about Communicable Diseases Control in Al-Nassiriyah City Hospitals 1514
Talal Mohammed Yousef, Wissam Jabbar Qassim, Zahid Jassim Mohammed

259. Evaluation Follicular Fluid Cytokines in Patients with Risk Factor for Development of Ovarian Hyper Stimulation Syndrome.....1521
Alaa K. Hameed, Alaa S. AL-Atabbi, Muna K. Mahmood

260. Methicillin-Resistance ***Staphylococcus Aureus*** (MRSA) in Hospitals: The Unwanted Guest 1530
Nadhim N. Tahir, Saad S. Hamim

261. Assessment of Health Workers Knowledge toward Occupational Health and Safety Program in Alkut City's Primary Health Care Centers.....1536
Duaa Malik Dhahir, Naji Yasser Al Mayahi

262. A Comparative Study of Arch Width, Overjet and Overbite between Bilateral Congenital Missing Lateral Incisor and Normal Class I Occlusion 1542
Zena Hekmat Altaee, Laith Hamood Aswad AL-Salmany, Maha Mishaal Turki

263. Application of Fractional Co2 Laser Modification of PEEK in Dental Implants, ***In vivo*** Study.....1548
Nahida Zahir Kamil, Basima Mohammed Ali Hussein

264. Study of Verbal Bullying in Early Adolescents (Case Study of Pallangga 5 Junior High School and Sungguminasa 3 Junior High School).....1553
Muh. Asrul Taufiq Arifuddin, Suriah, Sudirman Nasir, Muhammad Syafar, Lalu Muhammad Saleh, Nurhaedar Jafar

265. The Effect of Massage Therapy Method, Therapy Duration and Injuries on the Reduction of Pain in Knee Ijuries . 1560
Arif Setiawan, Soegiyanto, Tri Rustiadi, Rumini

266. Familial Phenotype of Waardenburg Syndrome in One Family: A Case Series....1569
Eka Savitri, Indra Irawan, Habibah S. Muhiddin, Fadly

267. Test Instrument Model Talk Athletes for Martial Branch Sports of Tarung Derajat....1577
Ipang Setiawan, Soegiyanto, Mugiyo Hartono, Tri Rustiadi

268. The Effect of Health Services, Supervisory and Team Orientation, Personnel Development and Tolerance of Error on Job Satisfaction Head of Health Centre in South Sulawesi Province....1586
Wardiah Hamzah, Suryanto, Oedojo, Sukri Palutturi, Nasruddin Syam

269. Basic Movement Standardization of the Pathol Sarang Martial Sport....1591
Putra Budi Kutniawan, Tandiyo Rahayu, Heny Setyawati, Mugiyo Hartono

270. Legal Constraints on the Enforcement of Covid-19 Health Protocol in Indonesia....1601
Husni, Mahdi Syahbandir, Muhammad Ya'kub Aiyub Kadir, Teuku Ahmad Dadek

271. Multipurpose Training Tool Development Branch of Artistic Gymnastics....1612
Tubagus Herlambang, Tandiyo Rahayu, Sulaiman, Tri Rustiadi

272. Management of Occupational Hygiene Therapy on the Ability to Perform Self-Care on Deficient Self-Care Patients Who are Cared for in RSKD, South Sulawesi Province....1621
Syahrir, Fatmawati

273. The Effect of Massage Therapy Method, Inventory Levels and Stress Levels on Kinase Creatine Levels....1627
Zainul Aziz, Soegiyanto, OktiaWoro K. Handayani, Mugiyo Hartono

274. Detection of Anti-GAD65 Antibodies in Sera of Diabetic Patients Using a Home-Made Latex Agglutination Kit.. 1636
Alaa S. Alattabi, Dhamiaa M. Hamza, Khalid Khalil Alaaraji, Sawsan M. Jabbar, Abeer Thaher Naji AL-Hasnawi, Ali Mansoor Jasim

275. Effect of Polycythemia on Serum Lipid Profile and Oxidative Stress....1640
Zainab Qasim, Muhammad Al-Yasiri

276. The Significance of Serum Albumin Level as an Indicator for Severity of Hypertensive Disorders in Pregnancy in Samawa City....1650

Abstract

Introduction: The literature on burnout research shows that more than 90% have used the Maslach Burnout Inventory (MBI).

Objective: The aim is to establish the psychometric properties in terms of reliability, sensitivity and validity of the Maslach Burnout Inventory (MBI) and to adapt it to the context of Moroccan teachers.

Method: This work was carried out through a process of translation and reverse translation of the original instrument by adapting the elements to the teaching profession. To determine the psychometric characteristics, we used Cronbach's alpha to determine reliability, exploratory factor analysis to extract factors and determine dimensionality, and confirmatory factor analysis to test the validity of the statistical model. Validation of the instrument was carried out on a sample of 170 teachers working in public schools in Ouezzane region (Morocco).

Results: Items 4, 5, 7, 9, 12, and 22 were relatively incoherent with respect to the other items, they were eliminated. The factorial analysis made appear three factors whose are explain 58.22% of the total variance. Cronbach's α for the whole questionnaire (0.761), for emotional exhaustion (0.819), depersonalization (0.850) and sense of personal accomplishment (0.785). The confirmatory factor analysis (CFA) showed satisfactory adjustment indices (X2 = 164,938 - df = 101- CFI = .937 - TLI = .915 - RMSEA = .037- P close = .984).

Conclusion: We propose to use Maslach's Theoretical Model for the Moroccan Sample in Future Research on the burnout of Moroccan teachers.

Keywords: *Psychometric, Validation, Maslach Burnout Inventory, Moroccan, Teachers.*

Introduction

Burnout is a chronic response to emotional and interpersonal stressors in work that is exhausting, cynical and ineffective[1]. It manifests itself in three forms: emotional exhaustion, depersonalization and the loss of the sense of personal accomplishment[2]. These three components are represented in the Maslach Burnout Inventory (MBI), whose success of his versions increases[3]. However, psychometric comparisons of MBI note both similarities and differences between several cultures[4-5] and cross-cultural comparisons of teacher burnout have yielded mixed results. For this reason, it is interesting to produce a diagnostic tool for professional burnout that is valid and specific to the cultural context of teachers in order to manage the risk that threatens the

e-mail: abdeslam.amri@uit.ac.ma

psychological health of these resources, which play a main role in the development of society[6].

In Morocco, there is no tool for assessing burnout valid and adapted to the context of teachers. For this reason, the objective of this research is to establish the psychometric validity of an Arabic translation of MBI based on empirical research and to provide a validated translation of the MBI specific to Moroccan teachers.

Material and Method

A. Measuring Instrument: Maslach Burnout Inventory MBI Questionnaire: The MBI is composed of 22 questions that explore three scales: emotional exhaustion (9 items), depersonalization (5 items), and the sense of personal accomplishment (8 items)[7].

1. **Response modalities and quotation:** The answers are given on a 7-point scale from "never" to "every day".
   - **Emotional Exhaustion (EE)** is assessed by adding items: 1, 2, 3, 6, 8, 13, 14, 16 and 20 (result between 0 and 54),
   - **Depersonalization (DP)** by adding items 5, 10, 11, 15 and 22 (result between 0 and 30).
   - **Personal Accomplishment (PA)** by adding the items: 4, 7, 9, 12, 17, 18, 19 and 21 (result between 0 and 48)[7].
2. **Translation of the questionnaire:** The translation of the MBI was done by two bilingual individuals working in the field of education, in collaboration with colleagues and specialists in the field of education to make the questionnaire specific to teachers. A review was conducted following the commentanalysis after the administration of the questionnaire to a pilot group of 20 teachers working in the public education sector.

B. Sample: The validation of the instrument was carried out with a sample of 170 teachers working in public educational institutions belonging to the management of Ouezzane (Morocco). 37.6% (n = 64) female and 62.3 %(n = 106) male. The mean age is 38.3 ± 8.9 years.

C. Statistical analyses: The approach recommended by Anderson and Gerbing (Anderson J, 1988)[8] to do a sequential analysis was adopted. The reliability of the instrument was examined by calculating the Cronbach's α coefficient for the three dimensions of the inventory. Then the data were subjected to an Exploratory Factor Analysis (EFA) to extract the factors and test the dimensionality of the questionnaire. The factor structure was studied by performing a principal component analysis (PCA) and varimax rotation. The Kaiser - Meyer - Olkin (KMO) measurement was calculated to assess the adequacy of the sampling. Ideally, the KMO should be greater than 0.60. The internal coherence of the global scale and the dimensions retained after rotation were evaluated using the Cronbach α.

For the adequacy of the model, we used different adjustment indices: the index square root approximation error of Steiger Lind (RMSEA), the normalized adjustment index (NFI), the Tucker - Lewis index (TLI), the comparative adjustment index (CFI) and P close. These indices are interpreted according to critical thresholds[9].

In general, values below 0.05 and 0.08 for the RMSEA are considered to indicate good and acceptable data adequacy respectively. The CFI and TLI should be greater than 0.9. The Pclose must be close to 1; the fit of the model is considered good when critical thresholds and listed standards are met. The statistical analyses were performed under SPSS 21 and AMOS 20.

Results

1. **Internal consistency of theoretical dimensions and deletion of items:** Using Nunnally's classification, which normally accepts Cronbach's α index above 0.70[10], the removal of items 4 and 12 from the entire scale increased this index from 0.68 to 0.75.

For depersonalization, the deletion of items 22 and 5 allowed Cronbach's α to increase from 0.67 to 0.76. For the sense of personal accomplishment, the elimination of items 9 and 7 allowed Cronbach's α to increase from 0.63 to 0.77. Items 4, 5, 7, 7, 9, 12, and 22 were therefore relatively incoherent with respect to the other items, so we decided to eliminate them from further analysis.

2. **Exploratory Factor Analysis (EFA):** The factorial analysis in principal axes with varimax rotation made appear three factors whose eigen values are greater than 1 and explain 58.22% of the total variance. The three dimensions are well defined and distinct on their respective factors; Thus, the first factor, which includes six items (1, 2, 3, 3, 6, 8, 14) constituting the emotional exhaustion dimension,

explains 37.05% of the total variance. the second, with six items (10,11,13,13,15,16,20) constituting the depersonalization dimension explains 13.79% of the total variance and the third with four items (17,18,19,21) constituting the personal achievement dimension, explains 7.37% of the total variance (Table 1).

Table 1: Matrix of components after rotation, percentages of explained variance and Cronbach's α of the three dimensions of the Maslach Burnout Inventory specific to Moroccan Teachers.

	Dimensions		
	EE	**DP**	**AP**
QI1	,72		
QI2	,79		
QI3	,57		
QI6	,72		
QI8	,65		
QI14	,66		
QI10		,71	
QI11		,69	
QI13		,71	
QI20		,59	
QI15		,80	
QI16		,55	
QI17			,75
QI18			,79
QI19			,73
QI21			,75
Cronbach's α.	0,81	0,85	0,79
% of the explained variance	37,05	13,79	7,38
% of total variance explained	58,22		
Precision measurement of Kaiser-Meyer-Olkin sampling (KMO)	0,88		
Bartlett sphericity test: Chi-square approximate Dl Significance of Bartlett	 1096,95 120 **0.000**		

EE: Emotional exhaustion, **DP:** Depersonalization, **PA:** Sense of personal accomplishment

In view of these results, the translation and application of the MBI in Arabic to a sample of Moroccan teachers keeps the dimensionality of the original construct. Cronbach's α on the global scale (0.761) as well as those for emotional exhaustion (0.819), depersonalization (0.850) and sense of personal achievement (0.785) are acceptable (Table 1).

3. **Analysis of the structure of the dimensions and sensitivity of the Maslach Burnout Inventory specific to Moroccan Teachers:** In order to clarify the existing relationships between the dimensions of the Maslach Burnout Inventory specific to Moroccan Teachers, the score for each dimension was calculated. Depersonalization (DP) and emotional exhaustion (EE) scores are positively correlated with each other, and negatively correlated with personal achievement (PA) scores, confirming the results of the MBI theoretical model. Similarly, to test the sensitivity gender and age variance analyses were conducted. The matrix of correlations between the three sub-dimensions and the age and gender variables shows the sensitivity of this 16-item questionnaire (Table 2)

Table 2: Means, standard deviations,correlations between the dimensions of the Maslach Burnout Inventory specific to Moroccan Teachers and between these dimensions and age and gender variables.

Variables	Means	Standard deviation	EE	DP	AP
EE	21,73	9,18			
DP	13,62	10,01	,61**		
AP	15,05	6,51	-,21**	-,445**	
Age	38,30	8,92	,16*	,04	,01
Gender			-,21**	-,28*	,05

** The correlation is significant at level 0.01 (bilateral).* The correlation is significant at level 0.05 (bilateral).

4. **Confirmatory Factor Analysis:** Finally, by respecting the quality of the adequacy indices of the Schermelleh-Engel, Moosbrugger & Muller model (Schermelleh-Engel K, 2003)[9], the Confirmatory Factor Analysis (CFA) carried out on the data of our sample showed that our tested three-dimensional model presents satisfactory adjustment indices. X2 = 164.94; DF = 101; $0 \leq X2 \leq 2df$; RMSEA = 0.03; CFI = 0.93 above the critical threshold of 0.9 and the P close of 0.98 is very close to 1 (Table 3).

Table 3: Quality thresholds of the model's adequacy indices According to Schermelleh, Engel, Moosbrugger & Muller 9

Indices	Model	Thresholds of acceptability	
		Good adequacy	Acceptable adequacy
X2	164,93	0 ≤ X2 ≤ 2df 0 ≤ 164,938 ≤202	2df <X2 ≤ 3df
Df	101		
CFI	0,93	CFI ≥ 0,90	
RMSEA	0,03	0 ≤ RMSEA ≤ 0,05 0 ≤ 0,037 ≤ 0,05	0, 05 <RMSEA ≤ 0,08
P close	0,98	0,10 <p ≤ 1 0,10 <0,984 ≤ 1	0,05 ≤ p ≤ 0,10

In view of this table, our model shows a good adequacy with the observed data, which allows us to formulate the validation of the three-dimensional character of the MBI translated into Arabic specific to Moroccan teachers. The 16-item Moroccan version specific to MBI teachers proposed by this research is therefore a validated structure.

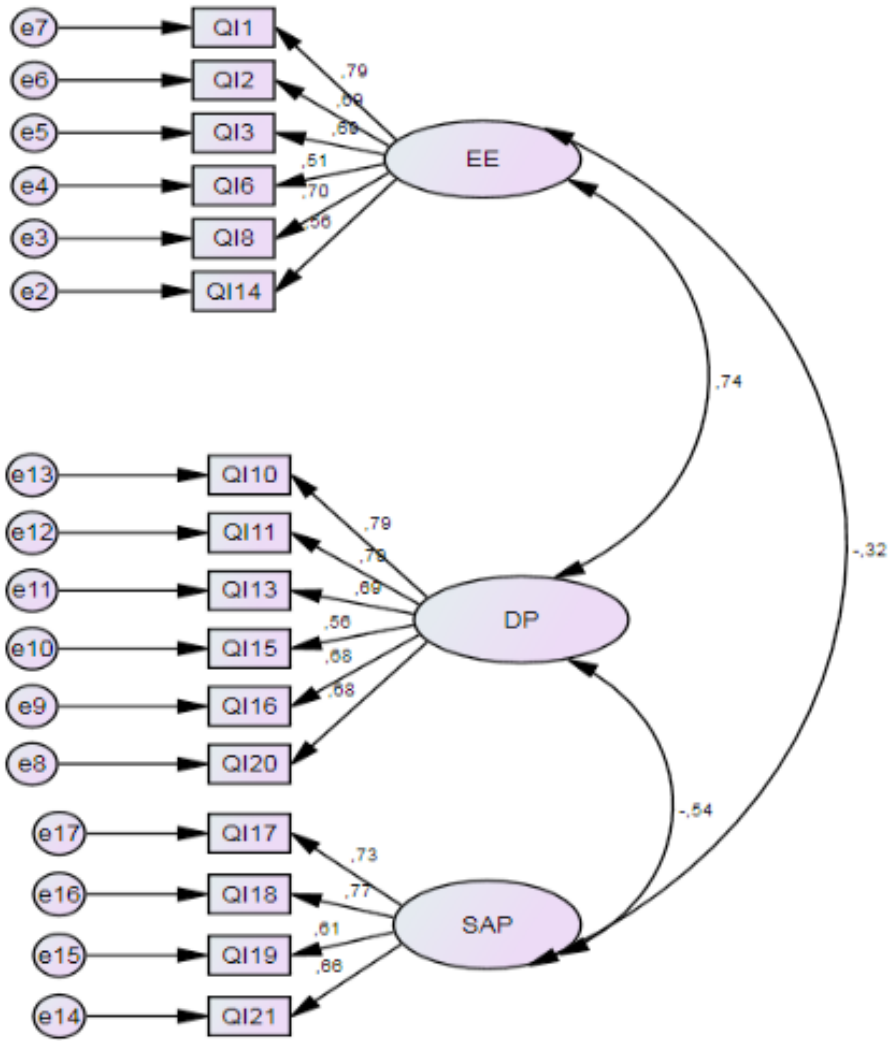

Figure 1: Confirmatory Factorial Analysis (CFA) performed by the maximum likelihood estimation method. MBI-ESM three-factor model (16 items). (X2 = 164,938 - df = 101- CFI = .937 - TLI = .915 - RMSEA =.037- P close = .984.

Discussion

The objective of this study was to construct and test the factor structure, internal reliability, sensitivity and validity of a scale of measurement translated into Arabic of professional burnout for Moroccan teachers, designed according to Maslach's three-dimensional theoretical model. The 16-item tool was validated on a representative sample of teachers from the Ouezzane exercising in northern Morocco, using a sequential analysis (internal coherence, EFA and CFA).Several validation tests have shown the inconsistency of some theoretical items of the 22-item MBI with the characteristics of the samples studied, which forced the researchers to exclude certain items to improve their model. Ellenge Denton and al, in the United States of America and Jamaica, had excluded 10 items, the teacher-specific version was validated at 12 items[11]. Aluja and al, in Spain, had excluded five items; the teacher-specific version for them was validated at 17 point[12]. Concerning our study, we excluded the items 4, 5, 7, 9, 12, and 22, and we kept a 16-item model. This inconsistency of these items could be explained by the characteristics of the teaching profession, the Moroccan language and culture. This confirms Wheeler's idea that further studies are needed on item-level analyses to explain the divergent results across occupations, languages and cultures[13]. The exploratory factorial analysis has retained the three dimensions for the 16-item MBI-ESM, which is consistent with several studies like those of Byrne and al in Canada[14], Yadama GN and Drake B in China[15], and Boles JS and al in the United States[16]. This study reveals a deviation from items 13, 16 and 20, which are theoretically associated with emotional exhaustion in the initial version, towards depersonalization. This deviation of theoretical items from one dimension to another has been observed in Abu-Hilal's study in 2018[17]. Confirmatory Factor Analysis (CFA) confirmed the validity of the 16-item MBI specific to Moroccan teachers with very satisfactory data adjustment indices (X 2 =164.938 - df = 101- CFI = 0, 937 - TLI = 0.915 - RMSEA = 0.037 and P close=0.984). This valid instrument is proposed for the evaluation of burnout among Moroccan teachers in future research. Concerning internal consistency, MBI-ES reliability analyses through studies systematically give Cronbach's alphas that vary between 0.8 and 0.9 for emotional exhaustion (EE), between 0.50 and 0.79 for depersonalization (DP), and between 0.69 and 0.82 for personal achievement (AP)[12]. For this study, Cronbach's alphas on the global scale (0.761) as well as those of emotional exhaustion (0.819), depersonalization (0.850) and sense of personal accomplishment (0.785) are satisfactory and comparable to those reported in several versions, indeed, the Cronbach alpha value of emotional exhaustion (0.819) is goobut remains lower than that of several studies. On the contrary, the depersonalization rate (0.850) is higher (Table 4).

Table 4: Cronbach's Alpha of the different dimensions of MBI-ES according to different studies. DPS: Depersonalization towards students. DPJ: Depersonalization towards work

Studies	Teaching cycle	Cronbach's Alphas of the different dimensions of MBI-ES			
		EE	DP		AP
Maslach & Jackson (1986)[7]	Primaryschool	0,90	0,79		0,76
Fernando & Perez (1996)[18]	Primary and secondary	0,88	0,61		0,82
Won sunchen & al (2014)[19]	-	0,91	0,78		0,78
Abu hilal & al (2018)[17]	Primary and secondary	0,87	DPS 0,47	DPJ 0,79	0,76
Our study (2019)	Primary and secondary	0,81	0,85		0,78

Conclusion

The results of the factors analysis of our study corroborate of Maslach's theoretical model, and a 16-item MBI model with better adjustment indices, demonstrating high conceptual validity, was proposed for use in the research of the psychological assessment of Moroccan teachers' burnout.

Conflict of Interest: The authors declare that there are no conflicts of interest.

Ethical Approval: The procedures were carried out in accordance with the recommendations of the internal Ethics Committee of the Ibn Tofail University Kenitra. This procedure were examined and approved by the Committee.

Source of Funding: This work is not financial.

COVID 19: Evaluate of Liver and Renal Function Tests in Iraqi Patients

Abdullah Ali Mohammed[1], Mahmood Nazar Mustafa[2], Sura A. Abdulsattar[3], Ahmed Salam Al-zaidi[4]

[1]Assistant Lecturer (M.Sc.) Department of Chemistry and Biochemistry, [2]Assistant Lecturer (M.Sc.) Department of Pathology and Forensic Medicine, University of Fallujah, College of Medicine, Iraq, [3]Prof. Dr. (PHD) Department of Chemistry and Biochemistry, Mustansiriyah University, College of Medicine, Iraq, [4](M.Sc.) Department of Medical Analysis, Al-Furat General Hospital, Iraq

Abstract

The clinical features of COVID-19 are varied, ranging from asymptomatic state to acute respiratory distress syndrome and multi organ dysfunction. We aim to evaluate renal and liver functions of patients with COVID 19. Laboratory results were obtained from 107 patients with laboratory-confirmed COVID-19 who were admitted to the only Al-Furat General Hospital in Baghdad, Iraq from March 3 to June 9, 2020 and followed up until recovery. Normal levels of renal functions were presented. Meanwhile elevated levels of alanine aminotransferase (ALT) was observed in 10% and of aspartate aminotransferase (AST) was observed in 40% of patients with COVID 19,yet on comparison of the results at entering with at recovery it was observed significant differences ($p<0.01$) of all patients. From these findings we conclude that the virus might be responsible for systemic inflammation.

Keyword: *COVID 19; liver enzyme; urea; creatinine; AST, ALT.*

Introduction

On 7 January 2020, a novel coronavirus was identified in the throat swab sample of one patient by the Chinese Center for Disease Control and Prevention (CDC), and was subsequently named as 2019nCoV by World Health Organization (WHO)[1,2]. The virus was identified as a coronavirus that had >95% homology with the bat coronavirus and > 70% similarity with the SARS- CoV. Environmental samples from the Huanan sea food market also tested positive, signifying that the virus originated from there[3]. The number of cases started increasing exponentially, some of which did not have exposure to the live animal market, suggestive of the fact that human-to-human transmission was occurring (2020)[4]. All ages are susceptible. Infection is transmitted through large droplets generated during coughing and sneezing by symptomatic patients but can also occur from asymptomatic people and before onset of symptoms[5]. The clinical features of COVID-19 are varied, ranging from asymptomatic state to acute respiratory distress syndrome and multi organ dysfunction. The common clinical features include fever (not in all), cough, sore throat, headache, fatigue, headache, myalgia and breathlessness[6]. Some patients with COVID-19 pneumonia also present with kidney injury, and autopsy findings of patients who died from the illness sometimes show renal damage. However, little is known about the clinical characteristics of kidney-related complications, including hematuria, proteinuria, and AKI[7]. Recently, there has been some insight into the impact of COVID-19 on other organs, as a number of reports have indicated that more than half of patients with COVID-19 showed varyinglevels of liver disease [8]. The median time from onset of symptoms to dyspnea was five day, hospitalization seven day and acute respiratory distress syndrome (ARDS) eight day. The need for intensive care admission was in 25–30%

of affected patients in published series. Complications witnessed included acute lung injuryacute cardiac injury, shock and acute kidney injury. Recovery started in the 2nd or 3rd wk[9]. The various diagnosis method such as serological, molecular, and radiological can help the health centers in the detection of SARS-CoV-2; radiological and serological techniques are the best method among the others and the radiological method is the most preferred one, able to diagnose the infection quickly and accurately with fewer false-negatives[10]. Liver impairment has been reported as a common clinical manifestation in patients with SARS-CoV infection, even if not a prominent feature of the illness[11,12].

Material and Method

This was a cross-sectional study, we analyzed biochemical data from electronic medical records of 107 hospitalized patients of Al-Furat General Hospital from Baghdad with COVID-19 (65 male and 42 female) for period (march 3 to June 9,2020). The data analysis included urea, creatinine, ALT, AST, and ALP twice: first at entering the hospital (group A) and second at recovery (group B).

Statistical Analysis: Continuous data were expressed as mean and standard deviation (SD). For the variables, paired test was employed to analyse the difference. All statistical analyses were performed using the SPSS 20.0 (SPSS Inc) software package. A (P value of < 0.05) was considered statistically significant.

Results and Discussion

The current evidence indicates that infection rates of COVID 19 are higher in male than in female (Figure 1), where 61 % (65 among 107) was male and 39 % (42 among 107) was female.

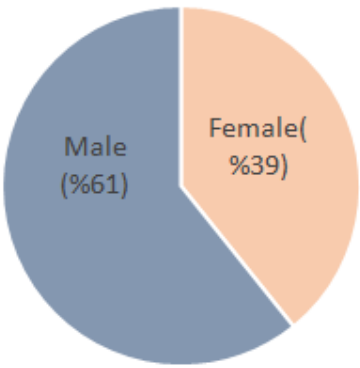

Figure 1: Covid 19 distribution among gender

The current results of COVID 19 distribution among age as shown in Figure 2 indicated that the most affected ages are between (20-40 year). The lowest affected ages was less than 20 year.

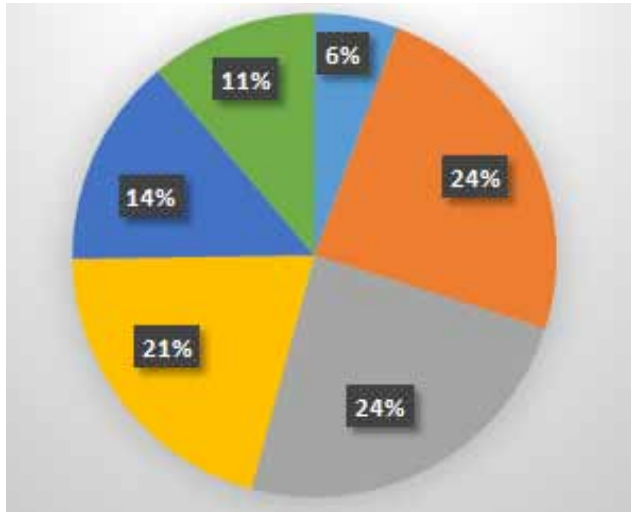

Figure 2: Covid 19 distribution among age where 6% : patients with age <20 year, 24% : patients with age range (21-30 year) & (31-40 year)respectively, 21%: patients with age range(41-50 year), 14%:: patients with age range (51-60year), and 11% : patients with age (61-70 year).

The results presented in Table 1 shows the levels of urea, creatinine, AST, ALT and ALP in sera of COVID 19 patients over two periods: the first when entering the hospital (group A) and the second when recovery (group B). Levels of urea, creatinine, AST, ALT and ALP were showed within normal level, however there were a highly significant differences ($p<0.01$) between groups in urea, creatinine, AST in both male and female patients .While the results of ALT indicated highly significant differences ($p<0.01$) only in male patients. For ALP the results of male indicated highly significant differences ($p<0.01$) and for female the result showed significant differences ($p<0.05$). In more detail the results indicted elevated levels of AST in 40% patients and of ALT in 10% patients, while no elevated levels of ALP was observed.

Table 1: The levels of urea, creatinine, AST, ALT and ALP in sera of COVID 19 patients

Parameter	Gender	Mean ±SD Group A	Mean ±SD Group B	P value
Urea (mmol/L)	Male	4.29	3.48	0.00
	Female	4.33	3.21	0.00
Creatinine (mmol/L)	Male	74.58	69.67	0.00
	Female	72.78	68.47	0.00

	Female	45.7857	36.1429	0.00
ALT (U/L)	Male	36.41	28.83	0.00
	Female	26.2381	24.2143	0.106
ALP (µkat/L)	Male	81.63	76.10	0.00
	Female	84.6667	76.7143	0.015

Although available sex-disaggregated data for COVID-19 show equal numbers of cases between sexes, current study indicates that infectious rates are higher in male than in female, and that may be due to sex hormone that contribute to different immunologic responses in men and women: As a general rule, estrogens promote both innate and adaptive immune responses, which result in faster clearance of pathogens and greater vaccine efficacy[13]. Conversely, testosterone has largely suppressive effects on immune function, which may explain the greater susceptibility to infectious diseases observed in men[14]. Notably, changes in sex hormone may further shape the immune response to pathogens[14]. Sex-related biological data may also be critical to investigate the contribution of sex hormones in inflammatory response. In particular, reduction in testosterone levels in aging men has been associated with increased proinflammatory cytokine levels [14] which may contribute to worse COVID-19 progression in older men. Sex differences in disease progression may also be linked to estrogen-induced decreased expression of angiotensin-converting enzyme 2[15] Pre-print studies are conflicting as to whether ACE2 expression in lung tissue is different between sexes[16,17]. Some patients with COVID-19 pneumonia also present with kidney injury, and autopsy findings of patients who died from the illness sometimes show renal damage[7]. In meta-analysis study of Zhu j et al indicated that some patients with COVID 19 (25.5%) presented elevated levels of renal functions[18]. The results of current study indicated that all patients presented normal levels of renal functions. Howeveron comparison of the results at entering with at recovery it was observed significant differences ($p<0.01$). Patients with abnormal liver tests were at increased risk of progressing to severe disease. The detrimental effects on liverinjury mainly related to certain medications used during hospitalization, and should be monitored and evaluated frequently[18].

Conclusion

Elevated levels of alanine aminotransferase (ALT) was observed in 10% and of aspartate aminotransferase (AST) was observed in 40% of patients with COVID 19,yet on comparison of the results at entering with at recovery it was observed significant differences ($p<0.01$) of all patients. As AST is not specific for liver damage, which indicated that the systemic inflammation induced by the virus might be responsible for these findingsnot related to certain medication.

Conflict of Interest Statement: All authors declare that they have no conflict of interest.

Assess the Level of Perception Regarding Instructor Caring Behaviour among Nursing Students at SRM College of Nursing

Abirami P.

Ph.D. (N), Professor, Dept. of Obstetrics and Gynaecology Nursing, SRM College of Nursing, Kattankulathur, Tamil Nadu

Abstract

Introduction: Caring is actually fundamental concept in nursing and manifests openness and honesty in the humanitarian area and the core of nursing science. Caring is the heart and soul of nursing, and people expect caring more than any other from nurses. Caring in nursing consist of two key dimensions, namely physical and mental. The psychological caring behaviors results in building confidence the feeling, faith and honesty of nursing: is caring a science.

Aim: A study to assess the level of perception regarding instructor caring behavior among nursing students at SRM College of Nursing, SRM Institute of Science and Technology, Kattankulathur.

Methodology: Non experimental descriptive research design was used to assess the level of perception regarding instructor caring behavior among nursing students. The study was conducted at SRM college of nursing, Kattankulathur, Kancheepuram district. 200 students who were studying at SRM college of nursing were selected by Non – probability convenient sampling technique. Research design was descriptive design. The data collection consisted two parts.Part A Demographic variables, Part B The structured questionnaire to assess the level of perception regarding instructor caring behavior among nursing students. It was validated and found to be feasible.

Results and Conclusion: The following conclusions were drawn and the basis of the findings of the study. 121 (54.3%) Students have perceived that their was a moderate level of caring behavior by the instructor, 90 (40.4%) students have perceived that their was a high level of caring behavior by the instructor.

Keywords: *Caring Behaviour,Instructor, Nursing students.*

Introduction

Caring is actually fundamental concept in nursing, and manifests openness and honesty in the humanitarian area and the core of nursing science.[1] Caring is the heart and soul of nursing, and people expect caring more than any other from nurses.[2] Caring in nursing consists of two key dimensions, namely physical and mental. The psychosocial caring behaviors result in building confidence, accepting the feelings, faith and honesty.[3]

It is decades since Florence Nightingle' time that scientists have been studying the nature, definition and assessment of nursing: is caring a science? And how can "caring" be taught?[4]

Having perceived the importance of caring in nursing teaching, students can learn professionalism.[5] A major part of nursing students' courses are taught in hospitals under the supervision of various clinical instructors.[6] Clinical instructors are the fundamental important agents in programming and acquiring clinical experiences,[7] because they can also establish the discipline and be a supportive agent for building students' effective communication, students' accountability and effective acquisition of scientific and clinical skill, and reducing their fear and anxiety through providing students with suitable corrective feedback and active presence as a source of reassurance and confidence.[8]

The nursing instructors are responsible for developing nursing curricula and using active learning strategies that will help students to learn caring behavior.[9] It is obvious that the clinical instructors preparing their students for entering clinical work places must meet the caring behavior.[10]

Previous studies showed that caring behavior played an important role in dynamism of instructor-student relationship.[11,12] In 2006, Wade and Kasper found that when instructors were taken as caring individuals, students also develop their own abilities. According to Wade, five special caring factor were effective in nursing students' perception of instructors caring, including instill confidence through caring, supportive learning climate, appreciation of life meaning, control versus flexibility, and respectful sharing. Based on Watson's theory of care, caring was represented by instructors and perceived by students in order to facilitate the acquisition of professional role, caring attitude, clinical self-confidence, clinical competency and interpersonal caring interactions in students.[13] Students learn caring through copying instructors' caring behaviors and experiencing caring with their interactions with instructors and other students.

Moreover, students perceive the presence or absence of support according to the type of contacts feedbacks receiving from their instructors,[14] to student instructors are individuals encouraging them, helping them to express their feelings, and inspiring them the self-confidence.[15] Furthermore, students make the flexibility. Kindness, respectfulness and being encouraging as the characteristic of instructor caring behaviors and they take the humiliation, rudeness, negligence and unavailability as instructor non-caring behavior. The instructor non-caring behavior arouses negative feelings in students, including ostracism, dissuasion, lost confidence, hopelessness, emotional turmoil[16] and increasing anxiety.[17] Wangletzkus believed that instructors could influence student learning positively and reduce the anxiety and loss interest in learning through increasing self-confidence, improving interpersonal relationships and help better understanding of role of education and becoming interested in education and therefore, students felts more freely to ask for help from instructors.[18]

Moreover, students took instructors' behavior "awkward and hostile",[19] as the instructors did not only reduce students' stress in the clinical environment but also increasing students stress and anxiety[20,21] Furthermore, inappropriate reaction to students' errors and unfair assessment made nursing students disappointed and unmotivated.[22] The absence of interest and motivation in student are of important barriers to the clinical education.[23]

Since caring behavior of clinical teacher is one of the most important and influential factors in the process of clinical instruction, so far has not been paid enough attention. In other words, there has been so little research couldn't present the clear image of caring dimension, therefore, the present study was conducted to determine the level of perception regarding instructor caring among nursing students' at SRM College of Nursing.

Methodology

A non experimental descriptive research design was used to assess the level of perception regarding instructor caring behavior among nursing students. The study was conducted at SRM College of nursing, Kattankulathur, Kancheepuram district. 200 students were studying in the SRM College of nursing were selected by Non–probability convenient sampling technique inclusion and exclusion criteria

Tools for Data Collection: The tool was consists of two sections. Section A deals with demographic details of students such as age, sex, year of study, prior education, religion, siblings, family, father or mother occupation, monthly family income, socio economic class and residence and section B consist of 30 questions to assess the level of perception regarding instructor caring behavior among nursing students. Each question was given 6 options.

a. Strongly disagree -1
b. Moderately disagree - 2
c. Slightly disagree – 3
d. Slightly agree – 4
e. Moderately agree- 5
f. Strongly agree – 6

Scoring Interpretation:

a. 1 to 60 – low level of instructor caring behavior (1 to 33 %)
b. 61 to 120 – moderate level of instructor caring behavior (34 to 67%)

121 to 180 – high level of instructor caring behavior (68 to 100%)

Ethical Consideration: Formal approval was obtained from the institution review board and institutional ethical committee of SRM Institute of Science and Technology, Kattankulathur, Kancheepuram district, Tamil Nadu, India.

Statistical Analysis: Descriptive and inferential statistics were used to assess and to associate the level of perception regarding instructor caring behavior among nursing students.

Results

Table 1: Frequency and percentage distribution of level of perception regarding instructor caring behavior among nursing students. N=200

S.No.	Level of perception regarding Instructor caring behavior	No. of Students	Percentage
1	Low	12	5.4%
2	Moderate	121	54.3%
3	High	90	40.4%

Discussion

The study finding was the among 200 selected samples regarding assess the level of perception regarding instructor caring behavior among nursing students at SRM college of nursing, SRM Institute of Science and Technology, Kattankulathur.

The first objective was to assess the level of perception regarding instructor caring behavior among nursing students: The finding were 12(5.4%) student have perceived that their was a low level of caring behavior by the instructor, 121(54.3%) student have perceived that their was a moderate level of caring behavior by the instructor, 90(40.4%) student have perceived that their was a high level of caring behavior by the instructor regarding instructor caring.

The second objective of the study was to associate the perception of instructor caring behavior among nursing students with their demographic variables: Considering the association of the perception of instructor caring behavior among nursing students with their demographic variables, elder and senior had more perception score than others. The level of perception with demographic variables was assessed using chi-square test. The level of perception of instructor caring behavior was associated with the variables such as sex (X^2= 0.945 P- 0.623), and age (X^2= 4.379 P- 0.625), and course (X^2= 16.560 P- 0.011*), and year of study (X^2= 12.672 P- 0.049*), and religion (X^2=8.970 P- 0.175), and numbers of siblings (X^2= 3.998 P- 0.406), and types of family (X^2= 5.551 P- 0.475), and fathers occupation (X^2= 10.738 P- 0.552), and family monthly income (X^2= 3.415 P- 0.970), and socio economic class (X^2= 17.808 P- 0.023*) and residence (X^2= 7.391 P – 0.117). Hence the hypothesis stated 'there is significant association of level of perception regarding instructor caring behavior among nursing students with their demographic variables are " course, year of study and socio economic status" and no significant association of level of perception regarding instructor caring behavior nursing students with their demographic variables are " course, year of study, and socio economic status.

Similar study conducted by Wade and kasperin Pennsylvania on 88 nursing student of the last year and 43 nursing student of the third year with the mean age of 23 (4.79) years and female percentage of 92.2% showed the total mean of 224.75(49.6) for the clinical instructor caring behaviors. The above total mean was higher and wade's study did not provide results for each dimension. Similar study done by Wang Letzkus in California on 138 nursing student of the third year and 101 nursing students of the last year from five academic semesters with the mean age of 24.51 (4.72) years and female percentage of 91.2% from three large nursing schools revealed the total mean for the clinical instructor caring behavior as 4.96 (0.69). The maximum and minimum mean was respectively related to instill confidence through caring and appreciation of life meanings [24]

Conclusion

The present study assed the level of perception of instructor caring behavior among the nursing students in SRM college of nursing, Kattankulathur. The results of the study concluded that the maximum students were 121(54.3%) perceived that there was a moderate level of caring behavior by the instructor 90 (40.4%) student have perceived that there was a high level of caring behavior by the instructor 12(5.4%) student have perceived that there was a low level of caring behavior by the instructor. Hence the perception of instructor caring behavior among the nursing students can be enhanced through compassion, competence, conscience, confidence and commitment among instructors working in the clinical area.

Acknowledgement: The author acknowledges Dr. C.kanniammal Dean, SRM College of Nursing for constant guidance, We would like to thank study participants for their constant support.

Conflict of Interest: No conflict of interest. In addition, this study was not funded

Statement of Human and Animal Rights: All procedures followed were in accordance with the ethical standards of the responsible committee on human experimentation (institutional and national) and with the Helsinki Declaration of 1975, as revised in 2008

Statement of Informed Consent: Informed consent was obtained from all the study participants for being included in the study.

Medical, Human Rights and Legal Analysis of the Existence of Lesbian, Gay, Bisexual, and Transgender in Indonesia

Aditya Yuli Sulistyawan[1], Tri Rahayu Utami[1]

[1]*Lecturer at Faculty of Law, Diponegoro University, Semarang, Indonesia*

Abstract

Globalization, which has now crossed the line, has had many impacts on all countries in the world including Indonesia. One of the impacts of globalization is the impact of deviant associations such as LGBT and it affects various countries. The emergence of the LGBT phenomenon, which is currently a hot topic of discussion by various parties in Indonesia, has raised pros and cons views on the legality of LGBT in society. LGBT legalization in various countries is currently encouraging LGBT survivors in Indonesia to urge the government to legalize LGBT. Therefore, this article will discuss the reality of LGBT and its legal arrangements in Indonesia and how to analyze the philosophy of law on the reality of LGBT in Indonesia. The results of the study show that according to the constructivism paradigm in the contextual review of legal philosophy in Indonesia, LGBT is not in accordance with the values of Pancasila as the nation's life guide.

Keywords: *LGBT,philosophy of law, Indonesia.*

Introduction

Globalization has a great impact on situations and conditions related to social relations, and cooperation between nations takes place quickly so that there is a mutual transfer of lifestyles, cultural values, thinking method, adopted systems, science and others, through relative contact fast too. It is in such an atmosphere and contacts that global political issues, global economy, global culture, and global defense and security develop.[1] Among the many impacts brought about by globalization, it cannot be denied that there is an impact on social deviations in terms of sexual behavior. The deviant behavior currently being discussed is the emergence of Lesbian, Gay, Bisexual and Transgender (LGBT) groups in society and is still being debated from all sides by various parties.

The history of the emergence of LGBT groups in Indonesian civilization, both documented in scientific and popular works, can be said to have begun to develop since the 1960s and boom in the 2000s.[2] In fact, organizations or advocacy organizations for this group grew in the 1980s, such as: Hiwad (Himpunan Wadam Djakarta); Lambda, Perselin (Indonesian Lesbian Association), all of which serve as a means of communication between perpetrators, observers and supporters of this group. The number of LGBT perpetrators in Indonesia reaches 3 percent of the total population of Indonesia or around 7.5 million people.[3]

The behavior of LGBT survivors, which is currently still hotly discussed, has received special attention from academics abroad as well as the study of feminism. But unfortunately, LGBT people still get an inappropriate position in Indonesian society. This rejection can be seen, among others, by the Islamic Defenders Front (FPI), which was recorded and explicitly restricted the movement of LGBT groups in the public sphere, as well as carrying out physical attacks against this group in various regions in Indonesia. The issue of LGBT is also a concern of domestic academics. This topic is discussed in almost all fields of study of science: law, religion, psychology, education, and sociology, even media and communication. Domestic scientific studies tend to analyze LGBT in particular in relation to its legitimacy in the eyes of law, social, culture, and religion. Humans as one of the contents of the universe are made the object of philosophy which examines it from various aspects. One of them is regarding his behavior. Some of these behaviors are then thoroughly investigated by the philosophy of law. Therefore, this article will discuss in depth the study of Legal Philosophy of the reality of

Lesbian, Gay, Bisexual and Transgender (LGBT) in Indonesia in order to understand the reality of LGBT from the point of view of legal philosophy. The purpose of writing this paper is to determine the reality of LGBT in Indonesia today so that we can understand the patterns and impacts of LGBT in society which is currently very troubling. In addition, it is also to understand the legal arrangements in Indonesia regarding the reality of LGBT so that it can be seen how the state's attitude towards the existence and reality of LGBT which is currently increasing in number. To achieve this goal, the problems that the authors discuss are the reality of LGBT and the legal arrangement in Indonesia and the analysis of legal philosophy on the reality of LGBT in Indonesia.

The Reality of LGBT and Its Legal Regulations in Indonesia: The definition of LGBT, in general, is associated with the term homosexual, which is the tendency to make someone of the same sex as a sexual partner and/or other emotional relationship. The rise of the LGBT phenomenon in Indonesia is closely related to the trend of liberal countries that provide recognition and a place for the LGBT community in society. LGBT is considered a part of modern society's life style which considers views of heterosexuality as conservative and does not apply to everyone. Social legitimacy arises with a priori scientific and theological defenses to strengthen claims about their existence and social purpose. This situation then made the LGBT movement spread so rapidly as a social epidemic.

In terms of quantity, there is no definite data on the number of LGBT people in Indonesia, but it is certain that it is increasing every year. According to a report from the Ministry of Health quoted from the National AIDS Commission, the number of men who have sex with men, aka gay, has reached millions. Based on the Ministry of Health's estimate in 2012, there were 1,095,970 MSM both visible and not. More than five percent (66,180 people) have HIV. Meanwhile, the UN predicts that the number of LGBT people will be much higher, namely three million people in 2011. In fact, in 2009 the gay population was only around 800,000 people. They take refuge behind hundreds of community organizations that support the tendency to have same-sex orientation.

In the perspective of Human Rights, pro-LGBT groups acknowledge that they have the right to vote for LGBT people. Because it is a human right, they demand protection. Human rights are a fundamental right inherent in human beings, universal and eternal, and therefore, must be protected, respected, protected, and not to be ignored, diminished, or deprived of anyone. In the Preamble of the Universal Declaration of Human Rights it is stated that "human rights must be protected by law, so that people will not have to choose the path of rebellion as a last resort to oppose tyranny and colonization".

The implementation of human rights without considering sexual orientation and gender and individual gender identity is not an easy matter. However, non-governmental organizations (NGOs), human rights and LGBT activists have consistently fought for LGBT recognition and rights, both at the national and international levels. Their endeavors have resulted in new developments on LGBT issues in Indonesia. The political reforms and democratization that have taken place in Indonesia have brought LGBT issues into the spotlight, leading to developments in LGBT organizations. Liberalism that upholds individual freedom has triggered the emergence of LGBT people who, although we think it is not normal, they think are normal and free to do as long as they do not harm others. Individual rights deserve protection, but individual rights are also limited by other individual rights.

Liberalism is one of the philosophical products of the Enlightenment in Europe which is very influential in the development of industrial society today. Liberalism believes that political legitimacy is influenced by the state's respect for the human rights of its citizens. We can see the close connection between liberalism and LGBT with the events of 26 June 2015, which became a historic day for LGBT people. On that day, the US Supreme Court's decision is believed to influence the decisions of many countries to participate in making similar decisions. In addition, there are already 22 countries from 204 countries that have been de facto recognized by the United Nations which fully legalize same-sex marriage in all regions of their country.[1] Most of these countries are countries with liberal ideologies.

In the legal system in Indonesia, as contained in the 1945 Constitution states "the right to life, the right not to be tortured, the right to freedom of thought and conscience, the right to religion, the right not to be enslaved, the right to be recognized as a person before the law, and the right not to be prosecuted based on retroactive law is a human right that cannot be reduced under any circumstances". This is in accordance with the provisions of Article 2,7 and 22 of the UDHR.

The state has the obligation to protect the people of Indonesian citizens regardless of their type, ethnicity, religion, race, ethnicity, or minorities and vulnerable groups (meaning that they are vulnerable to violence). The state has an obligation to fulfill the human rights needs of all Indonesian citizens regardless of ethnicity, religion, including minorities and vulnerable groups including LGBT people. In terms of protection, what must be guaranteed and provided in the context of LGBT from a human rights perspective is the protection of their human rights in the form of health insurance to be able to recover from their illness, as stipulated in Article 25 of the Universal Declaration of Human Rights, namely "everyone has the right to an adequate standard of life for health. and the welfare of himself and his family, including the right to food, clothing, housing and health care as well as necessary social services, and the right to security when he is unemployed, suffering from illness, disability, being a widow/widower, reaching old age or other conditions that cause him to be deprived. a living, which is beyond his control".

Based on applicable law in Indonesia, it is possible for people who have undergone sex change surgery to file a gender change in court. This is based on the jurisprudence of court decisions in cases of legal gender change for a male transsexual into a woman, namely Vivian Rubianti (born Iwan Rubianto) in 1973.[11]There are several rules that indirectly regulate LGBT. Article 292 of the Criminal Code explains that LGBT acts can be punished if the partner is an immature person under the criminal law. Even though the act was carried out without coercion or threat of violence, it is still an act that violates the contents of Article 292 of this Criminal Code. So far, what is prohibited by the Criminal Code is only homosexuals committed against minors. Article 292 of the Criminal Code does not explicitly prohibit homosexuals that are committed between adults. Therefore, it is necessary to emphasize the prohibition of homosexuality and adultery.[12] On the other hand, the Pornography Law (Law Number 44 of 2008) includes the term "deviant intercourse" as an element of pornography. In the explanation the meaning of this term includes, among other things, "intercourse or other sexual activity with corpses, animals, oral sex, anal sex, lesbian, and homosexuals". Although prohibitions apply to the production and distribution of pornography, these laws are understood by many gay men and lesbian women to criminalize homosexual sex. This is something interesting to discuss because in the regulation there is no prohibition for transgender people regarding deviant sexual relations.

In addition, Government Regulation Number 54 of 2007 concerning Adoption explicitly stipulates that adopting parents cannot be a homosexual couple. Adoption by an unmarried person is not permitted. These various regulations were further reinforced by other regulations, namely the Marriage Law (Law Number 1 of 1974) which explicitly defines marriage as the union between a man and a woman. Therefore, if the marriage occurs, the marriage is only considered never to have existed and no criminal sanctions are given to the perpetrator of the LGBT marriage.

Conclusion

The exposure of the LGBT phenomenon in Indonesia has become a hot polemic that is discussed from various sides by many parties. The reality of LGBT which is the basis of LGBT legality in Indonesia by pro LGBT people who base the Universal Declaration of Human Rights as its legalization must be reviewed based on the applicable law in Indonesia. Based on Pancasila in the name of Almighty Godhead, then LGBT in Indonesia cannot be legalized because every creature has its own nature, so that the protection of human rights referred to in the Universal Declaration of Human Rights must be adjusted again based on the 1945 Constitution which guarantees the protection of the Indonesian nation, however, protection for the healing of LGBT survivors is not about legalizing them to be accepted as a legally correct group. There are still many pros and cons related to LGBT in Indonesia which is also a moment for every party who is pro or contra to straighten up and present their arguments for the existence of LGBT. This can be initiated by bringing together various parties in a discussion/dialogue to present the arguments of each party in order to find a solution and solution to the LGBT problems that exist in Indonesia today. So it is hoped that with these discussion rooms, LGBT problems in Indonesia can be easily resolved and provide legal certainty whether it is legalized or just a mere hegemony.

The Role of Kinship and the Effectiveness of Traditional Customary Law on Inheritance System in Berbah, Sleman Regency

Agung Basuki Prasetyo

Lecturer at Faculty of Law, Diponegoro University, Semarang, Indonesia

Abstract

Indigenous peoples in Indonesia have a diverse family system, this leads to diversity in the devolution system. This form of parental kinship applies to the people of Berbah Sub-District of Sleman Regency. And whoath is in the heavens and the earth, and who is in the heavens and the earth, and who is in the heavens and the earth, and who is in the heavens and the earth, and whoth in the heavens and the earth, and currently, the people in Berbah Sub-District of Sleman Regency are predominantly Muslim, which could potentially influence the pattern of setting inheritance distribution in Islamic Law. There is still a strong principle of togetherness, the principle of deliberation, and the principle of benefit in the order of life of the people of Berbah District of Sleman Regency. Most importantly, they can accept the results of deliberation while upholding the principle of harmony.

Keywords: *Effectiveness, customary system, kinship, inheritance law.*

Introduction

Customary law communities in Indonesia, who have a variety of religions, beliefs, ethnicities, of course, have an effect on the different forms of kinship. This will lead to a diversity of patterns in the marriage system and inheritance in the life order of the Indonesian customary law community[1].

In Central Java which adheres to the parental kinship system, the kinship law is based on drawing maternal lines. In such a society, there are usually ways of mentas and seek or free marriages,namely, the usual form of marriage, husband and wife who are already married are free to determine their place of residence. Have left their home environment, or have been independent apart from their original family.

The formation of the national inheritance law, it is impossible to change the existing legal system, but still pay attention to the laws that live in the community, so that it can regulate the distribution of inheritance in Berbah District, Sleman Regency. Berbah District, Sleman Regency, is the study area. This is motivated by the life of the people who still uphold togetherness or communalism, more prominently social elements to help fellow citizens. So that relatively it can be said that they still have customs rules that are used as legal provisions that apply in social relations. In a community where customary rules apply, of course, they will be in conditions that are in harmony or do not face each other. So that the rules of inheritance customary law that have been obeyed for a long time should have a stronger influence on the life patterns of the people of Berbah District, Sleman Regency, which will become the legal provisions that are obeyed. This study aims to analyze the effectiveness of the inheritance customary law to be effective in Berbah District, Sleman Regency.

Research Method

This study is an empirical legal research using an empirical juridical approach. Empirical legal research is that law is identified as patterned behavior or understanding social meaning. The juridical approach, because this research stems from the principles and principles contained in a certain legal rule, it is used to see and analyze the problems to be examined. This empirical juridical approach is carried out to describe the real facts about the effectiveness of the Adat Adat Law in Berbah District, Sleman Regency. Primary data were

obtained from informants who were directly related to the problem being studied. Data analysis was carried out using qualitative analysis.

Inheritantance Value and Kinship System: The inheritance system is also inseparable from the kinship system adhered to by customary law communities in Indonesia. Patrilineal system draws on the lineage of the male ancestors, the position and influence of men in the inheritance law is very prominent, while the matrilineal system which draws the lineage of the female ancestors, the position and influence of women in the inheritance law is very prominent. In addition, parental/bilateral system, which draws lineages from two sides, both from the father's side and from the mother's side, the position of sons and daughters in the law of inheritance is equal and equal, meaning that both boys and girls are heirs of the assets the legacy of their parents[2,3]. Inheritance in the customary inheritance law contains regulations governing the process of forwarding and transferring property and intangible items (immaterial goederen) from a human force (generatie) to their descendants[4].

The parental kinship system adopted by the indigenous peoples of Central Java both influences and determines inheritance. It is evident that boys and girls are considered heirs in the view of Central Javanese customary law. This fact is in line with the view of Wirjono Prodjodikoro which states that the nature of inheritance in a particular society is closely related to the kinship nature of that society[5]. This has the consequence that sons and daughters are seen as heirs, because they are equally entitled to inherit the inheritance left by the heir.

This is in line with the post modern era (globalization era) and technological advances in urban areas, where women are equal and equal to men. Another role for a woman is to position herself as part of her community. The development of gender perspective studies also encourages changes and developments in the position of girls' rights in law, especially in terms of customary law[6].

Changes, especially in terms of inheritance, experience the effects of developments around them, which in general the rules of inheritance experience effects such[7] associal change/development, due to the tighter family ties, the loosening of clan and ethnic ties, inheritance rules from a foreign law which due to a certain relationship with religion get the authority that comes from religion, such rules for example from religious judges are applied to concrete events, even though the influence in inheritance law is smaller than in law marriage, depending on the strength of the inheritance law whether the law can survive or will there be a deep change.

Changes or developments will be made possible by the modernization of the way of thinking of members of indigenous peoples and law enforcers. In principle, customary law is people's law. As the people's law that regulates life that is constantly changing and developing, the maker is the people themselves. Therefore customary law undergoes continuous changes through decisions or settlements issued by the community as a result of consensus and deliberation through deliberation. Every development that occurs is always endeavored to have a place in the customary law system.

The effectiveness of traditional inheritance law in Berbah District, Sleman Regency: Berbah Subdistrict, Sleman Regency, is one of the government areas located on the outskirts of the Sleman Regency government, precisely on the border with Klaten Regency. In general, the people are effective in recognizing parental forms of kinship. Namely the kinship system, where there is a balance of position between husband and wife or withdrawing from the maternal line.

Based on the data above, after discussion with competent parties, it turns out that in accordance with Hilman Hadikusuma[8] opinion, that the parental kinship system, the blood relationship system is no different from the father's and mother's descent system and generally applies the custom of free marriage, where after the husband's marriage wife live independently.Then if you do not have children, the adoption of a male or female child may apply. So it can be understood that the parental/bilateral kinship system is a kinship system that draws lineages from two sides, both from the father's side and from the mother's side.

Further data obtained that in general in the people of Berbah District, there is an equal inheritance position between boys and girls, or in other words there is an equal right to the acquisition of inheritance from the heir, namely his parents. This is in accordance with the provisions that apply to the parental or bilateral system which draws lineage from two sides, both from the father's side and from the mother's side, the position of boys and girls in the law of inheritance is equal and

equal, meaning that both boys. as well as daughters are heirs of their parents' inheritance[2].

However, data is obtained, there are a small number of families who when dividing the inheritance, only boys get more inheritance assets with daughters, namely 2 to 1 in accordance with the provisions of Islamic Inheritance Law.

As understood, the inheritance customary law is the rules of customary law that govern how the inheritance or inheritance is passed on or shared from heirs to experts from generation to generation[9].

Of course, there is an atmosphere of mysticism for each family in dividing the inheritance for their children or generations of descendants. Because customary law is a dynamic law, it can adapt to certain situations and conditions. So when the provisions of the customary inheritance law are not implemented by certain families, it does not mean that the community must make a problem. The most important thing is that the principles of sharing his customary heritage are fulfilled.

Factors of traditional inheritance law in Berbah sub-district, Sleman regency: In connection with the factors that cause Adat Waris Law to be effective in Berbah District, Sleman Regency, data is obtained that the people of Berbah Subdistrict have a high level of compliance in carrying out the distribution of inheritance according to their customary provisions, because so far there have been relatively no internal conflicts between the heirs in a family who carry out the distribution of inheritance from their parents. The existence of a magical religious basis of thought in the people of Berbah District, Sleman Regency, on the implementation of inheritance distribution pays more attention to the heirs, parents and ancestors who have died calm in their graves. Mean while, the process of distributing inheritance by using the principle of cumunal or togetherness, the principle of deliberation and the principle of benefit in accordance with the provisions of customary law. So the most important thing is to be able to receive the results of the deliberations while still upholding the principle of harmony.

Furthermore, the results of the above research, conducted discussions with competent parties, so it can be understood that the customary inheritance law in the Berbah District generally shows a distinctive feature of the traditional Indonesian mindset, which is based on the principles that arise from a mind that is imbued with communal traits (togetherness), kinship, unity and oneness.

Some of the legal principles underlying the inheritance customary law are that according to the customary law system, inheritance property is not an entity that can be valued in money but is a unit that is not divided or can be divided according to types and kinds and based on the interests of the inheritors[10]. According to the customary law system, inheritance is based on equal rights, meaning that the rights of each heir are required to be the same in the process of passing on and passing on assets, and are placed on the basis of harmony in the process of distribution. Customary inheritance law adheres to the principle of open inheritance, which can be carried out while the heir is still alive and after he dies. So, customary inheritance law does not recognize any time when experts demand the opening of an inheritance. Settlement of inheritance using divine law principles, self-control, deliberation and consensus, harmony and kinship, and mutual rights.

Inheritance customary law is a form of the legal system that applies to the Indonesian people, especially those who are subject to customary law. Customary inheritance law is based or based on the principles of the characteristics of the traditional Indonesian school of thought, which have distinctive features, namely communal, religious magic, concrete, and cash (cash). Hazairin said that customary inheritance law has its own characteristics, namely that which originates from the minds of traditional communities with the form of kinship whose descent systems are based on patrilineal, matrilineal, and parental/bilateral[9]. Based on this distinctive feature, customary inheritance law is different from Islamic and western inheritance law. These differences stem from the way of thinking and way of life, such as customary inheritance law based on collective-communal rationalism, while western inheritance law is based on individualism.

Conclusion

In general, people in the Berbah District of Sleman Regency recognize parental forms of kinship. Namely the kinship system, where there is a balance of position between husband and wife or withdrawing from the father and mother line. There is an equal inheritance between boys and girls, or there is an equal right to the acquisition of inheritance from the heir, namely his parents.

The factors causing the inheritance customary law are still effective in Berbah District, Sleman Regency, namely: a). The people of Berbah District have a high level of compliance in carrying out the distribution of inheritance in accordance with their customary provisions, because so far there has never been an internal conflict between the heirs in a family that distributes inheritance from their parents. b). The existence of a magical religious basis of thought in the people of Berbah District, on the implementation of the distribution of inheritance, pays more attention to the heirs, parents and ancestors who have died calm in their grave. c). The process of distributing inheritance by more using the principle of cumunal or togetherness, the principle of deliberation and the principle of benefit in accordance with the provisions of customary law. So the most important thing is to be able to receive the results of the deliberations while still upholding the principle of harmony.

Suggestion: Village apparatus, especially in the Berbah sub-district, Sleman Regency, as well as related officials, so that they can better understand the substance of the distribution of inheritance carried out by their residents. So that there is certainty to provide legal protection for parties related to the distribution of inheritance.

Village apparatus in the Berbah Subdistrict, Sleman Regency, should be able to act as mediators in resolving disputes that may arise as a result of the distribution of inheritance carried out based on local customary law, in a fair manner.

Does Education Level Matter in Women's Risk of Early Marriage?: Case Study in Rural Area in Indonesia

Agung Dwi Laksono[1], Ratna Dwi Wulandari[2], Ratu Matahari[3]

[1]Rsesearcher, National Institute of Health Research and Development, the Indonesia Ministry of Health, Jakarta, Indonesia, [2]Researcher, Faculty of Public Health, Universitas Airlangga, Surabaya, Indonesia, [3]Researcher, Faculty of Public Health, Universitas Ahmad Dahlan, Yogyakarta, Indonesia

Abstract

Several studies inform that early marriage is correlated with several situations, including socioeconomic status, cultural wisdom, religious values, education, and internet access. The study was aimed at analyzing the effect of education level on women's risk of early marriage in rural areas in Indonesia. The study used data from the 2017 Indonesian Demographic and Health Survey. There were 2,252 women aged 19-24 years in a rural area in Indonesia who was taken as a sample. The variables analyzed included early marriage, education level, wealth status, and employment status. The final stage was used as a binary logistic regression test to determine the risk factors. The result found that women who have secondary education have a risk of 0.396 times compared to women who have primary education to experience an early marriage (OR 0.396; 95% CI 0.309-0.506). Women who have a higher education have a risk of 0.091 times compared to women who have primary education to experience an early marriage (OR 0.091; 95% CI 0.059-0.140). This finding informs that the education level was a determinant of the incidence of early marriage among women in rural Indonesia. The lower the education of a woman in a rural area, the higher the risk of experiencing an early marriage. It could be concluded that a low level of education is a risk factor for women's early marriage in rural areas in Indonesia.

Keywords: *Education level, early marriage, maternal health, reproductive health.*

Introduction

Early marriage is a phenomenon related to socio-economic conditions in developing countries. Early marriage can also be interpreted as child marriage. This phenomenon is increasing in number from year to year so that it becomes the focus of the target of the 5th point of the Sustainable Development Goals[1]. The prevalence rate of early marriage in Indonesia is high. The 2018 National Economic Survey (Susenas) noted that there were around 1.2 million adolescents who married before the age of 18[2]. The Indonesia Demographic and Health Survey 2002-2017 reported that 10% of Indonesian women became pregnant before the age of 18[3]. Moreover, the Indonesian government is also targeting a reduction in the prevalence of early marriage from 11.2% in 2018 to 8.74% in 2024 through the 2020-2024 National Medium Term Development Plan (RPJMN) so that by 2030 it can be targeted that the rate of early marriage is at 6.94%[2].

Early marriage in Indonesia is a common thing, given that marriage in traditional culture is part of the family's responsibility, not an individual desire, so that the family plays an important role in determining a marriage compared to the wishes of the child[4]. Globally, Indonesia is a country with the largest Muslim majority population, so that socio-cultural conditions are closely related to religious values held by a person[4,5]. The social construction in Muslim societies makes early marriage defined as the act of preventing unlawful sexual acts among adolescents[6,7]. Besides, the concept of maintaining virginity until marriage takes place also underlies the occurrence of early marriage in Indonesia[7].

Several studies have shown that early marriage is positively correlated with several situations, including socioeconomic status, cultural wisdom, religious values, education, and internet access[8–10]. In several regions in Indonesia, it has cultural values that support early marriage[11,12]. The social construction that is formed in

this community is a shame if in a family there are teenage girls who do not get married, there is still a strong opinion that the education of boys is more important than girls, and marrying children in adolescence can help ease the economic burden family[13–15]

Early marriage is a complex social problem that can have physical and psychological consequences. Teenage girls are very vulnerable to maternal mortality, child mortality, miscarriage, and giving birth to babies with low birth weight because knowledge related to motherhood is still very minimal, and reproductive organs are not ready to get pregnant and give birth[5]. Another impact is young women faced with conditions of dropping out of school, anxiety, victims of domestic violence, to the trauma of living life[10]. Seeing the wide impact of early marriage on young women, it is very important to equip adolescents with knowledge about reproductive health, including the long-term consequences of early marriage. Young women are still allowed to go to school as an alternative to improve the quality of life of young women so that they can compete for jobs and better livelihoods[6].

Based on the background description, this study was aimed at analyzing the effect of education level on women's risk of early marriage in rural areas in Indonesia. The results of this study are considered important for population policymakers to provide clear policy targets to reduce the rate of early marriage in Indonesia.

Materials and Method

Data Source: The study uses data sourced from the 2017 Indonesia Demographic and Health Survey (IDHS). The 2017 IDHS sample was taken using the stratification and multistage random sampling method. The unit of analysis for women aged 19-24 in rural Indonesia. Selection of the unit of analysis for women at ≤ 19 years of age because they had passed the age limit for early marriage. While the age limit is less than ≤ 24 years old, assuming there is no significant change in the demographic characteristics of the respondents to be tested to be a determinant of the incidence of early marriage. With the analysis unit, a sample size of 2,252 women in rural areas of Indonesia was obtained.

Data Analysis: In this study, the definition of early marriage is a marriage that is done before the age of 19 years old. This age limit refers to Law 16 of 2019 concerning Amendments to Law 1 of 1974 concerning Marriage. The independent variables analyzed in this study were education level, wealth status, and employment status.

Analysis at the initial stage was carried out using chi-square to determine the relationship between variables. Determination of risk factors is carried out using a binary logistic regression test because of the nature of the dependent variable. All statistical tests were carried out with the help of SPSS type 22.

Results and Discussion

Table 1. Descriptive statistics of education level and individual characteristics of the respondent (n=2,252)

Characteristics	Education Level						p
	Primary		Secondary		Higher		
	n	%	n	%	n	%	
Early marriage							***<0.001
No	96	15.7%	516	34.4%	101	70.6%	
Yes	514	84.3%	983	65.6%	42	29.4%	
Wealth status							***<0.001
Poorest	406	66.6%	687	45.8%	48	33.6%	
Poorer	119	19.5%	394	26.3%	26	18.2%	
Middle	59	9.7%	252	16.8%	27	18.9%	
Richer	19	3.1%	115	7.7%	21	14.7%	
Richest	7	1.1%	51	3.4%	21	14.7%	
Employment status							**0.002
Unemployed	387	63.4%	1055	70.4%	88	61.5%	
Employed	223	36.6%	444	29.6%	55	38.5%	

Note: *p <0.05; **p <0.01; ***p <0.001.

Table 1 provides descriptive statistics of the education level and individual characteristics of the respondent. It can be seen that early marriage is more dominant in women who have primary and secondary education. Based on wealth status, it can be seen that all categories of education level are dominated by the poorest women. Meanwhile base on employment status, it can be seen that all categories of education level are dominated by unemployed women.

Table 2 shows the results of binary logistic regression of early marriage among women in rural areas in Indonesia. Women who have secondary education have a risk of 0.396 times compared to women who have primary education to experience an early marriage (OR 0.396; 95% CI 0.309-0.506). Women who have a higher education have a risk of 0.091 times compared to women who have primary education to experience an early marriage (OR 0.091; 95% CI 0.059-0.140). These findings inform that education level is a determinant of early marriage among women in rural areas in Indonesia. The lower the education of a woman in a rural area, the higher the risk of experiencing an early marriage.Low education is probably closely related to an understanding of the risks of early marriage which is also low[16,17].

A study in Iran found that apart from the level of education, there are other factors related to education that are also a determinant of early marriage, namely the level of knowledge about the impacts of child marriage[18]. Several previous studies have informed that education is a positive determinant of performance output in the health sector[19–21]. Furthermore, low education is informed as a barrier to performance output in the health sector[22,23].

Table 2. The result of binary logistic regression of early marriage among women in rural area Indonesia (n=2,252)

Predictors	Early Marriage			
	Sig.	OR	Lower Bound	Upper Bound
Education level: Primary	-	-	-	-
Education level: Secondary	***<0.001	0.396	0.309	0.506
Education level: Higher	***<0.001	0.091	0.059	0.140
Wealth status: Poorest	-	-	-	-
Wealth status: Poorer	*0.032	0.776	0.615	0.978
Wealth status: Middle	**0.001	0.639	0.489	0.834
Wealth status: Richer	***<0.001	0.434	0.303	0.620
Wealth status: Richest	*0.045	0.603	0.368	0.988
Employment status: Unemployed	-	-	-	-
Employment status: Employed	*0.014	1.294	1.054	1.588

Note: *p <0.05; **p <0.01; ***p <0.001.

Women who have the wealth status of the poorer category have a risk of 0.776 times compared to the poorest women to experience an early marriage (OR 0.776; 95% CI 0.615-0.978). Women who have wealth status in the middle category have a risk of 0.639 times compared to the poorest women to experience an early marriage (OR 639; 95% CI 0.489-0.834). Women who have wealth status in the richer category have a risk of 0.434 times compared to the poorest women to experience an early marriage incident (OR 0.434; 95% CI 0.303-0.620). The richest women had a risk of 0.603 times compared to the poorest women to experience an early marriage incident (OR 0.603; 95% CI 0.368-0.988). This finding informs that poverty is a risk factor for early marriage among women in rural Indonesia.

Previous studies in various developing countries have found similar results that poverty is a risk factor for early marriage. Some of these countries are in South Sudan, Bangladesh, and India[24–27]. In the context in Indonesia, the phenomenon of early marriage tends to

occur in poor families of women. Early marriage is one practical way for poor families to get out of poverty. Marrying a girl from a poor family to a rich male family is a shortcut to a better life[28,29]with girls constituting the majority (76 per cent.

Finally, employed women have 1.294 times the risk of unemployed women experiencing an early marriage (OR 1.294; 95% CI 1.054-1.588). The results of this analysis inform that employed is a risk factor for early marriage among women in rural Indonesia. The employment status of women is closely related to the wealth status of the family. In developing countries, women tend to be responsible for domestic affairs. If women take part in earning a living, especially in non-formal manual labor, they often come from poor families[30–32].

Conclusions

Based on the results of the analysis, it was found that low-level education is a risk factor for women's early marriage in rural areas in Indonesia. Two other variables that were also found as risk factors were low wealth status (poor) and employed.

These findings provide clear information on targets for the government to reduce the incidence of early marriage in Indonesia. It is recommended that the government set targets that focus on those with low levels of education and the poor for policies to reduce the incidence of early marriage in Indonesia.

The Border–Non-Border Areas Disparities in Hospital Utilization in Kalimantan Island, Indonesia

Agung Dwi Laksono[1], Ratna Dwi Wulandari[2]

[1]Researcher, National Institute of Health Research and Development, Indonesian Ministry of Health, Jakarta, Indonesia, [2]Lecturer, Faculty of Public Health, Universitas Airlangga, Surabaya, Indonesia

Abstract

The border area is one area that needs government attention. The study was aimed at analyzing disparities in hospital use in Kalimantan based on the border-non-border area category. The study was conducted using data from the 2013 Indonesian Basic Health Survey. With the multi-stage cluster random sampling method, 69,043 respondents were obtained. In the final stage, a Multinomial Logistic Regression test was performed to determine any disparities. The study results found that the utilization of inpatient at the hospital for those living in the border area has a probability of utilization of 0.653 times compared to those who live in non-border areas. Those who live in the border have a lower chance than those who live in non-border areas of using inpatient hospital. The results of the study also found 8 other predictors that influence hospital utilization among adults in Kalimantan Island, Indonesia. The eight predictors are the type of place of residence, marital, education, work type, socioeconomic, health insurance, travel time, and transportation cost. It could be concluded that there was a disparity in hospital utilization in the border–non-border areas in Kalimantan Island, Indonesia. Those living in border areas have a lower likelihood of inpatient utilization than those living in non-border areas.

Keywords: *Disparities, hospital utilization, border areas, inpatient-outpatient, Kalimantan.*

Introduction

The government should guarantee access to the same health services for the people in its territory[1]. Every individual must have the same opportunity to access health services based on their needs[2]. Unlinking or devalue disparities utilization of health services is the concentration of health planners and policy makers[3]. This must be done as one of the efforts to improve the health care system performance indicator on a state.

As a referral facility, hospitals are often not built in border areas. This situation took place for reasons of transportation accessibility. The government builds hospitals in areas with better transportation availability. This condition is to ensure easier public access[4].

One of the areas that have a direct border with neighboring countries is Kalimantan Island. Kalimantan is an area that has the widest border with neighboring countries (Malaysia and Brunei Darussalam). Topographically, Kalimantan Island is dominated by forest areas.

Based on the background description, the study is aimed at analyzing disparities in hospital utilization in Kalimantan based on the category border areas - non-border areas. The results of this study can be used as input for health policymakers in determining policies that can have an impact on reducing disparities in border areas.

Materials and Method

The study was conducted by analyzing hospital utilization data from the 2013 Indonesian Basic Health Survey data. The 2013 Indonesian Basic Health Survey is a national scale survey conducted by the National Institute of Health Research and Development. The use of hospitals includes public and private hospitals. The unit of analysis in this study was the Indonesian population on Kalimantan Island, aged 15 years and over. At that age, it was assumed that the respondent is an adult, could make his own decision whether to use the hospital or not. Globally, Riskesdas was conducted with a sample size of 1,027,763 individuals. The sample

analyzed based on the unit of analysis was 69,043 respondents.

The category of hospital utilizationwas public access to the hospital, whether it was outpatient or inpatient. Based on the data received, outpatient variables were those carried out by the respondent in the past month. Being hospitalized was what the respondent did in the past year. The decision to use this time limit assumes that the respondent could remember both the outpatient and inpatient events well. The border area category was the regency/city on Kalimantan Island which was directly adjacent to neighboring countries (Malaysia and Brunei Darussalam). There were 7 border districts out of 55 regencies/cities, namely Sambas, Bengkayang, Sanggau, Sintang, Kapuas Hulu, Malinau, and Nunukan.

In the early stages of statistical analysis, Chi-Square was used for dichotomous variables and t-test for continuous variables. This test was used to assess whether there was a statistically significant difference in border-non-border areas. Based on the dependent variable (ordinal) category, the estimation was carried out using the binomial logistic regression test to study the disparities between border-non-border areas in hospital utilization and to check ORs and their statistical significance.

Results and Discussion

Based on Table 1, it can be seen that there is a statistically significant difference in hospital utilization between border-non-border areas observed in all characteristics, except age characteristics. Table 1 shows that both regions have greater utilization of inpatient care than outpatient care.

The population in Kalimantan predominantly lives in urban areas, both those categorized as border areas and non-border areas. Meanwhile, based on their gender, those on the border were more dominant by men, while those living outside the border were dominated by women. In general, those who were divorced mostly lived in non-border areas.

Table 1 shows that both the border area and the non-border area are dominated by people with primary school education and below. Meanwhile, the type of work in the border areas is dominated by those who work as farmers/ fishermen/labor, while those who live in non-border areas are dominated by those who do not have a job.

Table 1. Descriptive statistic(n=69,043)

Characteristic	Area		All	P

Travel time				0.000
• ≤15 Minutes	2136 (22.2%)	23065 (38.8%)	25201 (36.5%)	
• >15 Minutes (Ref.)	7485 (77.8%)	36357 (61.2%)	43842 (63.5%)	
Transportation Cost				0.000
• ≤IDR 15,000	2140 (22.2%)	25928 (43.6%)	28068 (40.7%)	
• >IDR 15,000	7481 (77.8%)	33494 (56.4%)	40975 (59.3%)	

Note: Chi-Square test was used for dichotomous variables and a T-test for continuous variables.

Based on socioeconomic status, the border areas are dominated by those in quintile 1 (the poorest), while those in non-border areas are dominated by those in quintile 5 (the richest). Based on the ownership of insurance in the two regions, it is dominated by those who have insurance managed by the government (Askes, Jamkesmas, Jamkesda, Jamsostek), although with a slightly higher proportion who do not have insurance at all.

Based on the travel time it takes for the community to get to the hospital, table 1 shows that in the two dominant regions the travel time is over 15 minutes. But with a bigger proportion in the border area. This condition is in line with the transportation costs required to get to the hospital. In the border area, people who need transportation costs more than IDR 15,000 have a larger proportion.

Table 2. The results of multinomial logistic regression (n=69,043)

Note: The reference category is "No Utilization"; 95% Confidence Interval for OR; *Significant at level 95%.

Table 2 presents the results of the multinomial logistic regression test to describe the differences in hospital utilization in border areas - non-border areas in Kalimantan. As a reference, the category "no utilization" was selected. Table 2 shows that in inpatient utilization in the hospital, those living in border areas had 0.653 times the probability of utilization compared to those living in non-border areas (OR 0.653; 95% CI 0.516-0.826). This means that those who live in border areas have a lower chance than those who live in non-border areas to use inpatient care at the hospital. Meanwhile, both outpatient and outpatient and inpatient utilization did not show a statistically significant difference between the two regions.

To overcome disparities in hospital utilization in border areas, the Government of Indonesia has issued a special policy on disadvantaged areas, borders, and islands. This policy was released to reduce inequality in health services in these special areas, including border areas[5,6].

Table 2 also shows the differences in hospital utilization based on the type of place of residence. Those who live in urban areas are 1.250 times more likely to benefit from outpatient hospital care than those who live in rural areas (OR 1.250; 95% CI 1.007-1.553). Based on their marital status, those who are single and married have a lower chance of utilization than those who are divorced. This condition applies to both outpatient and inpatient utilization.

Disparities of hospital utilization related to rurality do not only happen in Indonesia. The research results with the focus of disparities in many countries reporting the disparities existing, among others in China, Canada, and Ethiopia.[7–9]

Based on the education level, Table 2 shows that the categories of utilization, as well as outpatient and inpatient in the junior high school and senior high school, are likely to be lower than those with a college education. Meanwhile, in the category of work type, those who do not work have the possibility of using outpatient at the hospital 2.109 times those who work in other categories (OR 2.109; 95% CI 1.245-3.573). Higher education levels are often found to be positive predictors of health performance[10,11]. Otherwise, a low education level is a barrier to performance in the health sector[12,13].

Meanwhile, in outpatient utilization, the better the socioeconomic level, the better the possibility of outpatient utilization. This condition also applies to the use of inpatient. The same condition can be seen in the category of insurance ownership. Those with government-managed insurance had a better chance of using hospitals than those without, and those with privately-managed insurance had better utilization rates than those with government-managed insurance. Similar information is also found in previous studies[14,15]

Table 2 shows that those with a travel time of less than or equal to 30 minutes had a chance of using outpatient hospitals 1.514 times than those with a travel time of more than 30 minutes (OR 1.514; 95% CI 1.193-1.923). Meanwhile, those with transportation costs of less than IDR 15,000 were more likely to use inpatient care 1.243 times than those who had transportation costs of more than IDR 15,000 (OR 1.243; 95% CI 1.037-1.492). On a broader national scale, travel time and transportation costs are also found to be determinants of hospital utilization[16–18].

Conclusions

Based on the research results, it can be concluded that there is a disparity of hospital utilization in the border - non-border areas in Kalimantan Island, Indonesia. Those living in border areas have a lower likelihood of inpatient utilization than those living in non-border areas.

The results also found 8 other predictors that affect hospital utilization among adults in Kalimantan Island, Indonesia. The eight predictors are the type of place of residence, marital status, education level, work type, socioeconomic status, health insurance, travel time, and transportation cost.

Abstract

Background: Malaria is still one of the public health problems that can cause death primarily in high-risk groups. High incidence of malaria caused by unhealthy environment and patterns of Society behavior.

Objectives: Assessing the relationship between environmental factors and the society behavior factors with malaria incidence.

Method: This is a case-control study. Samples were taken using sampling purposive with criteria: Age 7-50 years and case groups were noted as clinical malaria patients. Data is collected by observing and filling out questionnaires. Risk factors are analyzed using the Chi-Square test, knowing the risks with the odds ratio. The dominant risk factors were analyzed using binary logistic regression.

Results: The variable associated with the malaria incident is ventilation (0,000), 2.5 (1.6-4.1), ceiling (0,015), 1.7 (1.1-2.7), puddles around the house (0,005), 1.9 (1.2-3.0), using of mosquito nets (0,000), 4.1 (2.4-6.4) and using mosquito repellent (0.001), 2,2 (1,4-3,5).

Conclusion: The proven environmental factors associated with malaria incidents are ventilation, ceilings, and puddles around the house. The Society behavior factor associated with malaria incidents is using mosquito nets and using mosquito repellent. Proves that the use of mosquito nets is a major risk factor for malaria incidents, with a risk of 4.3 times greater in those who when sleeping at night do not use mosquito nets.

Keywords: *Malaria, environment, society behavior, mosquito nets.*

Introduction

Malaria is still one of the public health problems. The World Health Organization (WHO) has called for an ambitious commitment to eliminate malaria in 35 countries by the year 2030. All heads of state in the Asia-Pacific region have been committed to eradicating national malaria. Malaria programs are faced with the challenge of malaria epidemiology changes. In this phase, an increase in the proportion of malaria imported and high-risk groups is often no longer children and pregnant women, but more associated with demographic risk factors and specific occupations for local arrangements. The transmission also becomes more geographically focused and is more likely to be reproduced through asymptomatic infections and non-falciparum.[1]

Each year more than 500 million people are infected with malaria and more than 1 million individuals die. Most cases in Africa and some Asian countries, Latin America, the Middle East, and some parts of Europe. The number of cases and deaths from malaria recorded in 2000 to 50% or more at the end of the year 2010 and

Corresponding Author:
Agung Sutriyawan
Research Scholar, Bachelor Programme Public Health, Bhakti Kencana University
e-mail: agung.epid@gmail.com

75% or more at the end of the year 2015.[2] Conditions in Indonesia tend to decline, but from 34 provinces in Indonesia, there are 8 provinces with Annual Parasite Incidence (API) numbers exceeding nationwide. The highest API took place in Papua (31.93) and West Papua (31.29) then East Nusa Tenggara, Maluku, North Maluku, Bengkulu, Bangka Belitung, and North Sulawesi.

Active and timely identification of related risk factors is crucial to target interventions to optimize malaria control.[3] Environmental risk factors affecting mosquito density Anopheles are divided into two, which are outdoor environment consisting of air temperature, humidity, rain, wind, sunlight, water currents, water puddle, ditch, paddy field, bushes, and large animal livestock cage. While the risk factors inside the house consist of gauze wire on ventilation, wall density, ceiling and clothes hanging.[4]

Bengkulu is one of the provinces whose API numbers still exceed national figures. Based on the health profile of Bengkulu Province in 2016 the number of malaria sufferers without blood supply is as much as 33,814, while with a blood supply test of 28,333 sufferers and test results there is 2,631 positive malaria. The highest case in North Bengkulu Regency was 1097 cases and the lowest in Heroiang district amounted to 4 cases, while in the city of Bengkulu amounted to 96 cases and 1 of them died. The city of Bengkulu kept the position to 6 highest in 10 regencies in Bengkulu Province whereas the city of Bengkulu is an urban area and Regency/ city with the most advanced economy in 10 districts/ cities and is mostly urban areas. Three health centers in Bengkulu with sufferers of the highest suspect malaria is Puskesmas Sukamerindu (1208 cases). There were increased cases of malaria in Puksesmas Sukamerindu in 2015 amounted to 926 sufferers, and increased in the year 2016 to 1,208 cases.

Material and Method

The design used in this study is quantitative case-control. Case population, all people who were declared clinical malaria based on data at the Sukamerindu Public Health Center. While control is taken from the case of neighbors who are free of malaria. The total sample of cases is 150 cases and 150 controls. Samples were taken using purposive sampling with the following criteria: Ages 7-50 years and case groups were recorded as clinical malaria patients. Data collection is done by two method, namely: first, interviews with the use of questionnaires, made as much as possible in a familiar atmosphere so that the interview can run smoothly and managed to get the information expected. Secondly, the observation method is conducted by researchers formally and informally to observe the activities in the field.

Data were collected by observing environmental variables: ventilation, walls, ceilings, standing water around the house, trenches around the house, and bushes around the house. While society behavior factors are taken by filling out questionnaires and interviews with respondents. Risk factors were analyzed using the chi-square test, to determine the magnitude of the risk using the Odds ratio (OR). After that, a multivariate analysis was performed using multiple logistic regression.

Findings:

Tabel 1. Characteristics of Respondents in the Study

Characteristics	n = 350	Percentage (%)
Age (years)		
< 10	14	4,7
10-19	55	18,3
20-29	97	32,3
30-39	60	20,0
40-50	74	24,7
Sex		
Men	178	59,3
Women	122	40,7
Education		
No school	58	19,3
Elementary school	62	20,7
Middle School	77	25,7
High school	52	17,3
College	51	17,0
Job		
Labor	43	14,3
Farmers	46	15,3
Traders	50	16,7
General employees	51	17,0
Government employees	16	5,3
Other	94	31,3

The results showed most of the participants aged between 20-29 years (32.3%) and men (59.3%). Most of the participants were low education and as workers.

Table 2. Chi-Square Test of Environmental Factors Related To Malaria Incidence

Environmental Factor	Malaria Incidence				P-value	OR(95% CI)	
	Case		Control				
	n=150	%	n=150	%		Lower	Upper
Ventilation							
Not Qualify	92	61,3	57	38,0	0,000*	2,588 1,625-4,122	
Qualify	58	38,7	93	62,0			
Wall

Using long sleeves when out of the house at night							
Yes	91	60,7	78	52,0	0,130	1,424 0,900-2,251	
Not	59	39,3	72	48,0			
The habit of hanging dirty clothes							
Yes	88	58,7	79	52,7	0,296	1,276 0,808-2,014	
Not	62	41,3	71	47,3			

* Significant < 0,05

The study showed that the society's behavior factors that were significantly related to the malaria incident were using mosquito nets (P = 0,000), OR = 4.1 (2, 4-6.4), and using mosquito repellent (p = 0.001), OR = 2.2 (1.4-3.5). While knowledge, attitude, using long sleeves when out of the house at night, and habit of hanging dirty clothes are not proven to be a risk factor for malaria incidents.

Table 4. Multiple Logistic Regression Test Results For The Final Risk Factor Related of Malaria Incidence

Risk Factor	r^2	P-value	OR	95% CI for EXP (B)	
				Lower	Upper
Ventilation	0,071	0,000*	2,892	1,692	4,755
Trenches around the house	0,034	0,005*	2,097	1,250	3,517
Using of mosquito nets	0,143	0,000*	4,362	2,594	7,335
Using mosquito repellent	0,053	0,008*	1,981	1.191	3,296

* Significant< 0,05

Multivariate analyses were conducted to view several risk factors that were jointly associated with malaria incidents. The dominant risk factors for malaria incidents are using mosquito nets.

Discussion

Environmental Factors: The study was conducted to assess the physical environmental factors of the home consisting of ventilation, Wall, and Ceiling. In the population, studies proved that ventilation is a risk factor for malaria events. Their risk of suffering from malaria if not attaching a gauze wire to the ventilation is doubling. The results of the survey have mostly used gauze on home ventilation. But in some houses that have been installed wire gauze, researchers found damaged wire gauze such as perforated and torn Karna has long been not replaced. But there is still also a house that does not use a gauze wire in ventilation, although it uses only partially ventilation as it is installed only in the room only. A study in Banjarnegara, Indonesia suggests that people who do not put mosquito nets in their home vents have significantly higher chances of having malaria. Wire netting is a barrier against mosquitoes entering the house.[5]

This study proves that the ceiling is a risk factor for malaria events. With a risk of 1.7 times greater in those

who live at home do not have a ceiling. Another study in Indonesia proved the same, in-house environmental factors that do not have a significant risk of malaria incidence is the condition of the wall.[6,7]

Environmental factors outside the home are proving to be a risk factor for malaria events are puddles around the house and life around the house. Studies in Uganda suggest that malaria-repellent mosquitoes breed in puddles and are often found near homes especially in rural communities in endemic countries. This is an indication that conditions that support the breeding of mosquitoes are allowed in the community.[8]Another study in Africa showed that the productivity of the highest Anopheles larva was observed in paddy fields, agricultural moats, and irrigation wells.[9]

The results of observation, some puddle of water such as the former Fish pond and the former pit around the respondent's house there is a mosquito larva, but this study is not done further to identify whether the larva found is a mosquito repellent Anopheles or not. Observation results are also obtained in almost every house adjacent to the ditch/ditch. When the trenches observation does not flow well so there are a lot of inundated trenches that could potentially be a place for mosquitoes to be missed.

This study cannot prove that a tightly-wall can prevent the occurrence of malaria. The results of the survey, in general, the wall condition of many respondents house made of concrete or cement. In some homes based on boards, some respondents closed the holes with tape or paper pasted between the boards so that mosquitoes did not go through the holes. The study also could not prove the bush around the house was a risk factor for malaria events.

The Gordon model known by a Trias epidemiology of infectious diseases is influenced by three main factors namely the host, agent, and environment.[10] The intended environment includes sanitation, the physical environment of the home, and the environment around the house. Poor sanitation is not only directly related to infectious diseases but can also affect the health of children.[11] The physical environment of the home such as ventilation and ceilings, as well as the environment that exists outside the home is closely related to the incidence of infectious diseases such as malaria.

Society Behavior Factors: The study also assessed the relationship of community behavior factors. The study reported that knowledge and attitudes were not proven significantly with the incidence of malaria. The study was conducted in urban areas, with most of the respondents well-educated, so that society has a good knowledge of malaria. Knowledge of taking medication, malaria test, and vector control by spraying at home. It is important to keep a clean trench around the house so that people are protected from illness.[12] The study in South Africa stated differently, that knowledge and attitudes were significantly related to the incidence of infectious diseases, one of which was malaria.[13]

This study proved that the use of mosquito nets was significantly related to malaria events. Some previous studies have expressed the use of mosquito nets associated with malaria events.[14,15] A double logistic regression test proves that the use of mosquito nets is a major risk factor of malaria. Chances of suffering from malaria in those who sleep at night do not use a mosquito net of 4.3 times larger. A previous study in Central Java province, Indonesia expressed sleep under mosquito nets is a technique to protect from mosquito bites. In this study, people who slept under the mosquito net had a lower chance (4.6 times) suffering from malaria than those who did not.[16]. Another study conducted in China-Vietnam suggested that the effect of the control-based prevention measures vector. Those who do not sleep under the mosquito nets have more than 5 times higher chances of experiencing unsymptomatic infections compared to those sleeping under the mosquito nets.[17]

The study also proved that Using mosquito repellent is a risk factor for malaria. The respondent did not use mosquito repellent because it does not like the smell of mosquito repellent. Studies in India have said that the use of mosquito repellent is effective in preventing mosquito bites. This study can not prove Using long sleeves when out of the house at night and the Habit of hanging dirty clothes is significantly related to malaria.

Conclusion

The proven environmental factors related to malaria incidents are ventilation, ceiling, and puddles around the house. The Society's proven behavior factors related to malaria incidents are using mosquito nets and using mosquito repellent. This study proves that using mosquito nets is a major risk factor for malaria incidents, with a risk magnitude of 4.3 times greater in those who do not use mosquito nets during nighttime sleep.

Conflict of Interest: All authors do not have a conflict of interest to declare related to research and work.

Abstract

Background: The Government provides directives related to the prevention of cases spread, but the number of cases still shows improvement. Community knowledge and attitudes influence the level of compliance with the Government's recommended COVID-19 deployment precautions.

Objectives: Assess knowledge, attitudes, and anxiety during the COVID-19 period.

Method: This is a quantitative descriptive study, sampling techniques using Snowball. Questionnaires have four parts, social-demographic, knowledge, attitude, and anxiety during the pandemic. Online questionnaires were developed using Google forms. Questionnaire link sent via email, Whats App, Facebook. Variables are summarized into frequencies and percentages using SPSS version 25.

Results: Total (61.3%) The respondent knows how to spread COVID-19, (97.4%) and (95.3%) Know COVID-19 is more dangerous for elderly and people have chronic diseases, (95.1%) Know the handwashing is a preventive effort, almost all of the participants agreed on hand washing, hand sanitizer, using a mask, (92%) Participants agreed to the screening COVID-19, (93%) Participants are willing to follow the Government's recommendation, (60%) Participants felt paranoid, (83%) Participants are always worried for themselves and those closest to you.

Conclusion: This study resulted in respondents having demonstrated good knowledge, positive attitudes, and feeling anxious during the COVID-19 pandemic

Keywords: *COVID-19, knowledge, attitude, anxiety.*

Introduction

Coronavirus disease Pandemic 2019 (COVID-19) is a problem that is happening in more than 200 countries in the world. COVID-19 has been identified as the cause of infectious respiratory disease outbreak in Wuhan, China.[1] The COVID-19 is highly contagious as most people do not have immunity against this new virus. Currently, COVID-19 attempts are performed only on the treatment of symptoms, treatment, and prevention of complications, but there have not been any medications that can cure this disease. Therefore, the best strategies to keep prevention such as keeping social distances or wearing masks may help us to prevent infections.[2] The governmental action of closing public services causes the collapse of the industry to negatively impact the economy.[3]

The spread of COVID-19 caused confusion, anxiety, and fear among the general public. A variety of research

e-mail: agung.epid@gmail.com

on COVID-19, many facts are constantly changing and many myths are not prevalent in the general population regarding the prevention and management of infections. This is sometimes very annoying for certain individuals.[4] The absence of appropriate protective measures is the main cause of concern among common society. At the community level, there is distrust of others in the spread of disease and the role of government in tackling the plague. Especially in countries like Indonesia which is a populated country without strong health infrastructure, it is the cause of concern. Some levels of panic also appear in public due to the unavailability of basic protective measures.

COVID-19 was first reported in Indonesia on February 2, 2020, until today it continues to increase. Governments, media, physicians, researchers, celebrities, police and other community stakeholders urge communities to avoid public gatherings such as sports, religious ceremonies, family events, meetings and classes in schools, this is done to prevent the spread of Coronavirus infections.[4] Disbelief in the spread of disease and the role of the government in tackling the plague so that the spread of COVID-19 in Indonesia is difficult to overcome. To comply with the Government's recommendation, the public requires knowledge of the spread, the title, prevention of COVID-19. Facts in the field still many people ignore the importance of social distance due to attitude problems. Anxiety and community concerns generally affect every individual. Recent evidence suggests that individuals who are in isolation and quarantine experience anxiety, anger, confusion.[5] The knowledge and attitude of society largely affect the level of adherence to the prevention of disease spread that has been recommended by the Government. Therefore, it is important to study these domains in the Indonesian population. Based on the relevance of all of the above factors, researchers aim to assess the perceived knowledge, attitudes, and anxieties during the COVID-19 pandemic in Indonesia.

Material and Method

The type of research used is quantitative descriptive. This approach was done to see a clear and accurate picture of the knowledge, attitudes, and anxieties during the pandemic COVID-19 period in the Indonesian population. Sampling techniques using Snowball. A semi-structured online questionnaire was developed using the Google form, with the consent form also available. Questionnaire links are sent via email, Whats App, Facebook, or any other social media to the respondent. The questionnaire contains the characteristics of social-demographic, knowledge, attitudes, and anxiety in sequence, which the respondents must answer. This study is an online study, participants who can participate in this research if they have a social media account and have access to the Internet. The age of participants in this study is more than 18 years old, able to understand Bahasa Indonesia, and willing to approve respondents. Data collection started on 16 June 2020 hours 13.00 WIB and closed on 23 June 2020 at 12.00 WIB.

The questionnaire consists of 9 questions about knowledge covering the way of transmission, symptoms, prevention, and treatment of COVID-19. The questionnaire attitude during the pandemic contains 15 question items that are graded with a scale Likert 5 points, namely: very disagree, disagree, hesitate, agree, and strongly agree. Anxiety during a pandemic associated with a COVID-19 infection has 17 question items, rated using a Likert scale of 4 points, namely: never, sometimes, often and always. The analysis in this study uses descriptive statistics using SPSS version 25. Variables are summarized into frequency and percentage distribution based on the question item given to the respondent

Findings:

Table 1. Socio-Demographic of the Participants (n = 1051)

Socio-demographic Characteristics	Frequency	%
Age (years)		
≤ 20	163	15,5
21 - 30	511	48,6
31 - 40	277	26,4
41 - 50	67	6,4
51 - 60	28	2,7
> 60	5	0,5
Gender

The characteristics of socio-demographic participants are shown in table 1. Among the participants who responded, 511 (48.6%) 21 – 30 years of age group, 732 (69.6%) Female gender, 782 (74.4%) College, 383 (36.4%) Working as a private employee, 894 (85.1%) Islamic faith.

Table 2. Knowledge of COVID-19 among Research Participants (n = 1051)

Knowledge Items	Frekuensi	%
1. COVID-19 spreads through		
a. Touch	116	11,0
b. Sneezing	287	27,3
c. Kissing	4	0,4
d. answered everything (touch, sneezing, kissing)	644	61,3
2. COVID-19 can be transmitted from people without symptoms		
a. Yes	983	93,5
b. Not	41	3,9
c. Do not know	27	2,6
3. Pets in the House can transmit COVID-19		
a. Yes	422	40,2
b. Not	365	34,7
c. Do not know	264	25,1
4. COVID-19 more dangerous for elderly		
a. Yes	1024	97,4
b. Not	12	1,1
c. Do not know	15	1,4
5. COVID-19 is more dangerous in people who have chronic diseases		
a. Yes	1002	95,3
b. Not	12	1,1
c. Do not know	37	3,5
6. Symptoms		
Fever		
a. Yes	836	79,5
b. Not	215	20,5
Headaches		
a. Yes	325	30,9
b. Not	726	69,1
Cough		
a. Yes	708	67,4
b. Not	343	32,6
Sore throat		
a. Yes	665	63,3
b. Not	386	36,7
Fatigue		
a. Yes	299	28,4
b. Not	752	71,6
Difficulty breathing		
a. Yes	784	74,6
b. Not	267	25,4
Chest Pain		
a. Yes	177	16,8
b. Not	874	83,2
7. Isolation of a person who has symptoms COVID-19 can stop the spread of COVID-19?		
a. Yes	1000	95,1
b. Not	24	2,3
c. Do not know	27	2,6
8. Frequent hand washing can stop the spread of COVID-19?		
a. Yes	999	95,1
b. Not	30	2,9
c. Do not know	22	2,1
9. Antibiotics can treat COVID-19		
a. Yes	251	23,9
b. Not	499	47,5
c. Do not know	301	28,6

Source: Primary Data, 2020

Knowledge among study participants on COVID-19 is described in Table 2. The majority is 644 (61.3%) Virus

COVID-19 spreads through touch, sneezing and kissing, 983 (93.5%), 1024 (97.4%) Know COVID-19 more dangerous for elderly, 1002 (95.3%) Know COVID-19 is more dangerous in people who have chronic diseases, 1000 (95.1%) Know the isolation of a person who has symptoms COVID-19 can stop the spread of COVID-19, and 999 (95.1%) Know often hand washing can stop the spread of COVID-19.

Table 3. Attitudes About COVID-19 among Participants Research (n = 1051)

Attitude Items		Responses that answered agree and strongly agree (N = 1051)	
		F	%
1	When I meet friends, I always greet them without shaking hands	908	86,4
2	When I meet my friends and colleagues, I always welcome them without hugging	956	91,0
3	I wash my hands using soap or hand sanitizer regularly	986	93,8
4	I usually use masks to protect myself from the risk of contracting COVID-19	1027	97,7
5	If I have any of the symptoms associated with COVID-19, I will tell the health worker	957	91,1
6	If I make a contact or interaction with the infected COVID-19, I am willing to be in isolation at home within a certain period until it proves that I am not infected with COVID-19	1014	96,5
7	If I make a contact or interaction with the infected COVID-19, I was willing to be isolated in the hospital within a certain period until it proved that I was not infected with COVID-19	947	90,1
8	If there is a laboratory test available to detect the COVID-19, I am willing to do so	972	92,5
9	If there is a vaccine available for COVID-19, I am willing to be vaccinated	902	85,8
10	I usually follow the latest updates or news about the spread of COVID-19 in my country	902	85,8
11	I usually follow the latest updates or news about the spread of Covid-19 around the world	752	71,6
12	If the counseling is held about the COVID-19 in the region where I live, I will follow him	634	60,3
13	If it is as smooth or a brochure that includes information about COVID-19, I will read it and follow the instructions described therein	912	86,8
14	I am willing to follow the Government's recommendation regarding the prevention of COVID-19 transmission	987	93,9
15	I am willing to buy COVID-19 preventive equipment such as masks and hand sanitizer	983	93,5

Source: Primary Data, 2020

Preventive measures to limit the spread of COVID-19 and their responses are presented in table 3. The majority of participants agreed when meeting friends or colleagues did not shake hands or embraced. Almost all of the participants said they agreed to wash their hands using soap or hand sanitizer regularly and use masks to protect themselves from the transmission of COVID-19. Most study participants agreed in isolation at home or in the hospital if they made contact with the COVID-19 or infected people. Approximately 92% of participants agreed to the screening for COVID-19. The results of the study were obtained about 93% of the participants were willing to follow the Government's recommendation regarding the prevention of COVID-19 transmission and willing to purchase COVID-19 preventive equipment such as masks and hand sanitizers.

Table 4: Anxiety about COVID-19 among Participants Research (n = 1051)

During the COVID-19 Pandemic		Responses that feel anxious (often and always) (N = 1051)	
		F	%
1	How often do you think about COVID-19	855	81,4
2	How often do you feel paranoid/scared about COVID-19	618	58,8
3	How often do you avoid partying	939	89,3
4	How often you avoid direct social contact	882	83,9
5	How often you avoid large meetings directly such as worship, meetings, and more	873	83,1
6	How often you order food online	384	36,5
7	How often do you talk to your friends about the COVID-19 pandemic	778	74,0
8	How often you have trouble sleeping due to worry about the spread and transmission of COVID-19	273	26,0
9	How often you feel affected by news coverage in newspapers and TV	540	51,4
10	How often you feel the need to buy and store all the needs at home	569	54,1
11	How often do you feel scared if anyone in your neighborhood is reported to be infected with COVID-19	635	60,4
12	How often you feel you need to use a hand cleanser	970	92,3
13	How often you feel you need to constantly wash your hands using soap or hand sanitizer	958	91,2
14	How often do you feel worried about yourself, and the people closest to the spread and transmission of the COVID-19?	874	83,2
15	How often you use masks even without any obvious symptoms of infection	972	92,5
16	How often the story of COVID-19 makes you feel frightened so that it leads to unnatural behavior towards others	318	30,3
17	How often are the stories of COVID-19 that make you panic on social media	321	30,5

Source: Primary Data, 2020

Anxiety among study participants on COVID-19 was presented in table 4. More than 85% of the participants were busy with a COVID-19 pandemic, around 60% of the paranoid participants with a mind contracted COVID-19 during a pandemic. About 85% of participants avoided party, social contact, and avoided meetings such as worship, meetings, and others for fear of being displaced by COVID-19. About 83% of participants reported worrying for themselves and their closest people during the ongoing pandemic. About 92% of participants always use masks even without any obvious symptoms of infection.

Discussion

Indonesia is still not able to suppress the transmission of COVID-19 effectively. The population of Indonesia participates in this study, most of the community has a good knowledge of the spread of COVID-19, which is evident from some of the questions we ask. Respondents to this study who have higher knowledge are also due to most of the respondents over the age of 20. The results of the study were conducted in three countries (Jordan, Saudi Arabia, and Kuwait), that the higher COVID-19 knowledge scores proved to be significantly related to the age and achievement of education.[6] Knowledge is considered important in the prevention efforts of COVID-19 if society has good knowledge, hopefully, the community is more obedient in the prevention efforts of COVID-19 recommended by the Indonesian Government. The study in China obtained 89% demonstrated sufficient knowledge about COVID-19. Knowledge is a prerequisite for building preventative beliefs, shaping positive attitudes, and promoting positive behaviors, and individual cognition

and attitudes towards the disease affect the effectiveness of certain strategies and behaviors.[7]

Participants of this study were optimistic about the prevention of COVID-19, most of the participants took the precaution of spreading the infection by COVID-19, such as: not shaking hands and hug when meeting friends or colleagues, always use masks when exiting the house and wash hands using soap or hand sanitizer regularly. Previous research showed that most of the population took the COVID-19 precautions, i.e. not traveling in crowded places,[8] and using masks.[9] Study in Vietnam stated that the prevention of the transmission of COVID-19 was by hand washing and using face masks.[10]

Most of the study participants agreed to be isolated at home if they made a contact or interaction with the COVID-19 infected person. Disconnecting the suggested transmission chain is to implement social distance as well as isolation and quarantine to the general public who have symptoms of COVID-19. The patient's isolation is very effective in stopping the transmission if early detection is possible before a clear virus release.[11]

Findings from this study, often the respondents wash their hands using soap, sanitizer, and mask. This shows the respondent's concern for the action to maintain personal hygiene to avoid the COVID-19 infection. Respondents ' awareness of the COVID-19 was seen in their behavior, as the frequent avoidance of going to the party, avoiding meetings, and also avoid going to the place of worship. Anxiety was also reflected by their fears that there was a COVID-19 transmission, even a quarter of respondents were struggling to sleep because of a COVID-19 spread. The level of anxiety in respondents can cause unnatural behavior such as anxiety, worry, or anger.

Excessive anxiety in society will have an impact on mental life. Therefore, it is important to address the difficulties of mental health in a pandemic situation. Study in India states that when anxiety occurs a broad population, it can lead to panic for the community, which causes the resources to quickly run out. Research in Iraq states that social media has a significant impact on the spread of fear and panic related to the COVID-19 outbreak, with a potential negative influence on mental health and psychological wellbeing of society.[12]

Conclusion

Our study showed that respondents had a good knowledge of the way the transmission and prevention of COVID-19 had a positive attitude during the pandemic and some respondents felt anxiety during the COVID-19 pandemic. There need to be mental health consulting facilities for the community throughout Indonesia to reduce the level of public anxiety.

Phacoemulsification Under Topical Anaesthesia Combined with Anxiolytic

Ahmed Mohammed Al-Samak

Lecturer of Ophthalmology at Al-Zahraa College of Medicine, University of Basrah, Basrah, Iraq

Abstract

Background: Local anesthesia in ocular surgery is a technique that mostly used now. Many type of procedures were applied including retrobulbar, peribulbar, subconjunctival and topical anesthesia.

Aim: To study the efficacy of tetracaine topical anesthesia technique combined with anxiolytic midazolam in cataract surgery, and to test patient's and surgeon's conviction by this method.

Patients and Method: Prospective study of one hundred three patients with dense cataract in Al-Basira eye center with mean age of 60.32 years (range: 50-70). Patients were 57 male and 46 female. Topical anesthesia was encouraged by intravenous anxiolytic, midazolam 0.1 mg/kg weight given in the beginning of surgery. We used a special patient's pain scoring and intraoperative surgeon's conviction score to analyze the reliability of this method. The study period lasted from October 2019 to March 2020.

Result: All patients had peaceful success phacoemulsification with an average surgery time of 15-20 minutes. Minimal or no movement noticed during surgery. No need for more anesthesia as there were no intolerable pain.

Conclusion: Cataract surgery can be safely and effectively done by topical anesthesia using this method.

Keywords: *Local anesthesia, phacoemulsification, anxiolytic.*

Introduction

Topical anaesthesia for cataract surgery is used after development of phacoemulsification as there is a closed system ignoring the squeezing of patient. In topical anesthesia, there is no risk of ocular perforation, muscle injury, or central nervous system effect and relatively short convalescent period as that may occur in other types of local anesthesia like retrobulbar and peribulbar[1]. By this method there is a blockage of trigeminal nerve supply of the cornea and the conjunctiva only, and there is no effect on the intraocular structures of the anterior segment[2]. There are many types and drugs used, the main two types are eye drops and viscous gel and drugs are lidocaine and tetracaine. Patient comfort, and history of allergy to local anesthetic agents decide the type of drug used[2]. Different sedatives or analgesics are used combined with topical anaesthesia including; midazolam, diazepam, propofol, fentanyl and ketamine[3]. We want to assess the effectiveness of tetracaine eye drops topical anesthesia technique combined with anxiolytic,midazolam in cataract cases, and to test patient's and surgeon's satisfaction with this method.

Patients and Method

Prospective study of one hundred three patients with dense cataract in Al-Basira eye center with mean age of 60.32 years (range 50-70), were set for phacoemulsification cataract extraction under topical

anaesthesia combined with anxiolytic. Patients were 57(53.4%) male and 46(46.6%) female.

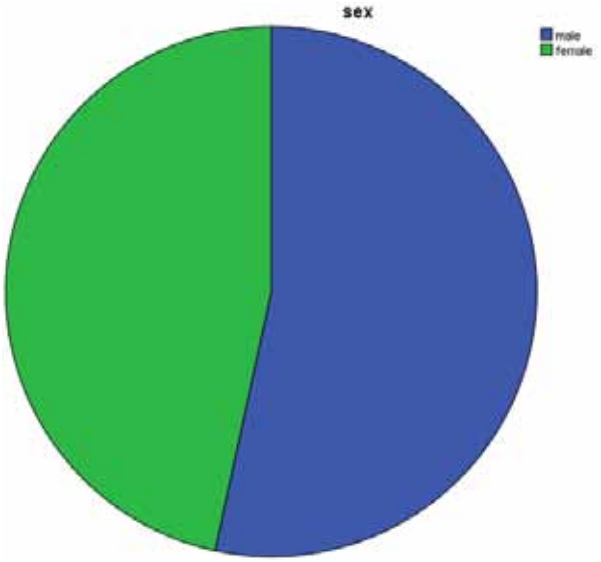

Table 1. Patient's pain scoring

Score	Patient condition
0	No pain or discomfort
1	Some discomfort
2	Mild tolerable pain
3	Moderate pain
4	Severe pain

Table 2. Intraoperative surgeon's conviction score

Score	Surgeon conviction
0	Poor
1	Fair
2	Good
3	Excellent

At the beginning, we talk with our patients to illustrate what we will to do. The topicalanesthetic tetracaine eye drops was used. Two drops of tetracaine were put in the conjunctival sac. Another 2 drops of tetracainewas put in the conjunctival sac of the other eye to conceal blinking reflex of the contralateral eye. The topical anaesthesia was combined with intravenous anxiolytic, midazolam 0.1 mg/kg weight. Patients were observed, in addition to the vital signs, forpain and sensitivity to light and touch. A reconnaissance method (Tables 1 and 2) used for both the patients and the surgeon that had been done in recovery room postoperatively, a subjective pain score for the patient was obtained .Surgeon conviction were reported intraoperatively.

Inclusion Criteria: Patients from 50-70 years old with dense cataract, no other ocular pathology, no previous ophthalmic surgery and controlled systemic diseases if they had (ASA class II and III).

Exclusion Criteria: Patients with early cataract, had any ocular pathology like glaucoma, had any uncontrolled systemic diseases, and uncooperative patients.

Results

All patients had peaceful success phacoemulsification surgery with an average surgery time of 15-20 minutes. Minimal or no movement notice during surgery. The analysis was performed using the Statistical Package for the Social Sciences (SPSS) version 23 software.

Table 3 showed that 89 patients (86.4%) had no pain noticed intraoperatively and 9 patients (8.7%) had some discomfort especially to light and 5 patients (4.9%) had mild tolerable pain from the speculum with statistically significant association (P- value =.ooo).

Table 3. Subjective pain scoring

Pain Score	No. of Patients	Percentage	p-value
No pain	89	86.4	.000
Some discomfort	9	8.7	.000
Mild pain	5	4.9	.000
Moderate pain	O	0	
Severe pain	O	0	
Total	**103**	**100%**	

Surgeon conviction was excellent in 93 patients (90.3%), good in 7 patients (6.8%) as there was some blinking and fair in only 3 patients (2.9 %) of the patients where there was blinking and eye movement as demonstrated in(table4) with statistically significant association (P- value =.ooo). No patient was converted to another way of anesthesia.There were no any serious complications postoperatively.

Table 4. Surgeon's conviction score.

Surgeon conviction	No. of Patient	Percentage	p-value
Excellent	93	90.3	.000
Good	7	6.8	.000
Fair	3	2.9	.000
Poor	0	0	
Total	**103**	**100**	

Discussion and Conclusion

This study offer the use of a safe anesthetic technique with least intervention. It provided acceptable analgesia and surgery can be performed without akinesia or sort of ocular movement.Topical anesthesia is justified as a means of improving safety without causing discomfort to the patient even in complicated cases of cataract surgery[4] and has negligible complication as compared with other ways of local anesthesia using in ophthalmic surgery that increases intraocular pressures like retrobulbar and peribulbar[5]. Potentially life-threatening complications exist with all techniques except topical/intracameral local anesthesia[6]. In addition, significant pain during anesthetic administration, intraoperative surgery, or after the cataract procedure, is the major reasons for low patient satisfaction[7]. Many surgeons do not consider akinesia an important requirement for cataract surgery, but some prefer to operate under conditions in which eye movements are blunted if not complete paralyzed[8].Many type of drugs have been tried as a supplement to local anesthesia [9], but here we choose midazolam.

Midazolam is benzodiazepine medication used for anesthesia0.1mg per kg weight.Midazolam is commonly utilized for conscious sedation/anxiolysis/amnesia[9] that is mean it can prevent physical and psychological discomfort, and it provides good cooperation of the patient, and it arrest patients recall of intraoperative events The patient is awaked and cooperative and obey commands.Midazolam alone may produce optimal block conditions for the patient and it is satisfactory during the procedure[10]. The choice of sedatives is highly variable and opioids may be added for better pain relief and higher patient satisfaction. Any side-effects delaying the discharge after sedation are undesirable[11]. Alsoit is undesirable for patients with ocular surgery to get postoperative nausea and vomiting with strain oneye [12].All these undesired effects did not occur with our patients using this way of anesthesia.

We noticed previously on usingdiazepam for example, the patients went into deep sleep and awaked suddenly with abnormal reaction that affects the cooperation of the patients. Although there were patient squeezing and eye movement, they were neither a trouble to the surgeon nor to the patient. No additional supply of anaesthesia was required. We as surgeons were satisfied with this method, patients accepted this type of anaesthesia for the surgery of other eye in the future.

The Influences of Antenatal Care, Postnatal Care and Early Initiation of Breastfeeding on an Exclusive Breastfeeding Pattern in the Working Area of Manukan Kulon Public Health Center at Surabaya City

Azizi Pridasari[1], Lutfi Agus Salim[2]

[1]Bachelor Student in Department Biostatistics and Demography, Faculty of Public Health, Universitas Airlangga, Surabaya, Indonesia, [2]Associate Professor in Department Biostatistics and Demography, Faculty of Public Health, Universitas Airlangga, Surabaya, Indonesia

Abstract

Exclusive breastfeeding is very important for babies to maintain their immune system, brain intelligence, emotion stability and to protect babies from various diseases that are causes of death. Breastfeeding will also benefit the mother, which will reduce blood loss during menstruation, restore maternal weight as before pregnancy, reduce the risk of breast cancer, and uterine cancer. The purpose of this study was to determine the influences of antenatal care, postnatal care and early initiation of breastfeeding on an exclusive breastfeeding pattern. The samples used in this study were mothers who had babies aged 7-12 months in June to August 2018 as many as 48 respondents in the working area of Manukan Kulon Health Center in Surabaya. This study used the descriptive and bivariate analyses. The obtained results were antenatal care (p = 0.001), postnatal care (p = 0.002) and early initiation of breastfeeding (p = 0,000). During pregnancy the majority of mothers make complete antenatal care visits with a frequency of 10 times, antenatal care is very important for mothers, especially the pattern of breastfeeding. In addition to the importance of antenatal care visits, mothers who have given birth and are entering the postnatal care phase are required to make postnatal care visits. Socialization from health workers and the support of closest people are required in order to achieve the exclusive breastfeeding.

Keywords: *Exclusive Breastfeeding, Early Initiation of Breastfeeding, Antenatal Care, Postnatal Care.*

Introduction

Exclusive breastfeeding is the provision of breast milk that is given to infants without giving any additional food and drinks to the baby until the age of 6 months and given the breastfeeding as early as possible(1). Breast milk as the main food of babies is very important because breast milk contains 60% of the nutritional needs of babies. Breast milk has several benefits including the intelligence of baby's brain, the baby's emotion stability and can protect the baby from various diseases that are causes of death. Breastfeeding will also benefit the mother, which will reduce blood loss during menstruation, restore maternal weight as before pre-pregnancy and reduce the risk of breast cancer and uterine cancer. Although breastfeeding and breast milk are very beneficial, it is estimated that 85% of mothers in the world do not give an exclusive breastfeeding as recommended by WHO (2002). Many mothers in many countries do not provide exclusive breastfeeding due to various factors such as social, cultural, economic and political (2).

Breastfeeding can affect the reduction in newborn mortality from the first day of birth by 16% and will reduce death possibility by 22% if the newborn is given breast milk within the first hour after birth. In 2012, the 0-5 month's infants received exclusive breastfeeding with the percentage of 41.5%. In 2013, infants who received exclusive breastfeeding were 38%. In 2014, the coverage of exclusive breastfeeding in Indonesia did not meet the strategic plan target of 52.3% while the target to be achieved was 80%. However, in 2015, the national target of exclusive breastfeeding was reduced to the amount of 39% so that the national target was able to be reached.

In 2016, the results of nutrition monitoring in Indonesia showed that newborns received early initiation of breastfeeding with the percentage of 51.9%. The infants who were aged 0-5 months received an exclusive breastfeeding with the percentage of 54%, while infants who were aged 0-6 months get exclusive breastfeeding by 29.5%. On these results, it can be concluded that babies received a complementary food of breastfeeding at the age of 5 months on average.

According to the Isrono study in 2013, mothers who gave exclusive breastfeeding in the working area of Serpong Public Health Center were as much as 14.6% [3]. In conclusion, the information that has been given and obtained were not necessarily going to be implemented properly.

Methodology

The samples used in this study were mothers who had babies aged 7-12 months in June to August 2018 as many as 48 respondents. The technique used in this study was by carrying out the data retrieval in the working area of Manukan Kulon Public Health Center at Surabaya City by using the simple random sampling formula.

The dependent variable in this study was the pattern of exclusive breastfeeding. Meanwhile, the independent variables in this study were the influence of antenatal care, postnatal care and early initiation of breastfeeding.

Data analyses in this study were using descriptive and bivariate analyses. Descriptive analysis was used to describe the characteristics of each independent and dependent variables. Meanwhile, bivariate analysis was used to see the relationship between each independent and dependent variables using a logistic regression analysis. Through the logistic regression test, the value of p would be obtained, which in this study used a significance level of 0.05. Research between the two variables was said to be meaningful if it had a value of $p < 0,05$ which meant Ho was rejected and H1 was accepted. It was said to be meaningless if it had $p >= 0,05$ which meant that Ho was accepted and H1 was rejected. Bivariate analysis was carried out to select candidates for influential factors.

Results

Antenatal care is a midwifery service for pregnant women that aims to maintain the health of pregnant women and ensure normal birth can be carried out at least four times during pregnancy to confinement. Antenatal care visits are grouped into 2 groups, namely complete and incomplete antenatal care visits. Research result shows that the majority of respondents made a complete antenatal visit from the beginning of the pregnancy to giving birth with a total of 44 people (91.6%). Respondents who had an incomplete antenatal care visit were as many as 4 people (8.4%) with a frequency of 4 time visits.

Postnatal Care (PNC) is the period after the placenta is born and the period ends when the uterus organs returns to its pre-pregnancy state. At this time, the body is making both physical and psychosocial adjustments to the birth process that starts immediately after the placenta is born until the body can adjust to perfection and ends when the uterine organs return to their pre-pregnancy state which lasts for 6 weeks. Research result shows that all respondents take the postnatal care visit after giving birth, although with different frequency of visits. The most postnatal care visit was 2 times with a percentage of 60.4%, followed by postnatal care visits as much as 3 times by 31.3% and the least was one time postnatal care visit with a percentage of 8.3%. The percentage was very good because postnatal care visits were suggested to be done at least once after giving a birth.

The coverage of early initiation of breastfeeding among respondents in the working area of ManukanKulon Public Health Center at Surabaya can be categorized as good, because most respondents initiated early breastfeeding immediately after the baby was born with the percentage of 91.7% and 8.3 % did not initiate early breastfeeding.

Table 1. Distribution of Breastfeeding Pattern Based on Ante Natal Care (ANC) Visits

ANC Visit	Breastfeeding Pattern				Total	
	Exclusive		Non-Exclusive			
	n	%	n	%	N	%
Complete	4	9,1	40	90,9	44	100,0
Incomplete	0	0,0	4	100,0	4	100,0
Total	4	8,3	44	91,7	48	100,0

Distribution results on the pattern of breastfeeding based on Antenatal Care visit in the table 1 shows that most respondents with complete ANC visits gave breastfeeding with a non-exclusive pattern with a percentage of 90.9% while respondents who did not routinely make ANC visits gave breastfeeding with a non-exclusively pattern by 100%.

Table 2 Distribution of Breastfeeding Pattern Based on Post Natal Care (PNC) Visit

PNC Visit	Breastfeeding Pattern				Total	
	Exclusive		Non-Exclusive			
	n	%	n	%	n	%
1 time	0	0,0	4	100,0	4	100,0
2 time	4	3,18	25	86,2	29	100,0
3 time	0	0,0	15	100,0	15	100,0
Total	4	8,3	44	91,7	48	100,0

Based on the results in table 2, the majority of respondents visited Postnatal Care twice with a frequency of 29 respondents. The respondents who visited PNC twice and determined the pattern of non-exclusive breastfeeding had a lower percentage with a total of 86.2%. Meanwhile, the respondents who visited PNC once and three times and determined the pattern of non-exclusive breastfeeding to their babies had a greater percentage by 100% respectively.

Table 3 Distribution of Breastfeeding Pattern Based on the Early Initiation of Breastfeeding (EIB)

EIB	Breastfeeding Pattern				Total	
	Exclusive		Non-Exclusive			
	n	%	n	%	n	%
Yes	4	9,1	40	90,9	44	100,0
No	0	0,0	4	100,0	4	100,0
Total	4	8,3	44	91,7	48	100,0

The pattern of breastfeeding based on Early Initiation of Breastfeeding in table 3 shows that there were more respondents who did the EIB than those who did not. Respondents who did EIB mostly gave non-exclusive breastfeeding to their babies with the percentage of 90.9%. Meanwhile, the respondents who did not give an EIB tended to give a non-exclusive breastfeeding to their babies with a percentage of 100%. The analysis of the independent and dependent variables by using logistic regression analysis (a = 0,05) are as follows.

Table 4 Bivariate Analysis of Antenatal Care, Postnatal Care and Early Initiation of Breastfeeding

Variable	Sig	Explanation
Antenatal Care	0,001	Significant
Postnatal Care	0,002	Significant
Early Initiation of Breastfeeding	0,000	Significant

Based on table 4, the logistic regression analysis obtained, there were 3 variables that influenced the pattern of breastfeeding to mothers, namely antenatal care (p = 0,001), postnatal care (p = 0,002) and early initiation of breastfeeding (p = 0,000).

Discussion

Antenatal Care Factor: Antenatal care is a health service for a mother during her pregnancy which carried out in accordance with established antenatal care standards. The visit of pregnant women to health services is recommended as follows; once in the first quarter, once in the second quarter and at least 2 times in the third quarter [(4)]. Ideally, every woman who is pregnant wants to have a pregnancy check in order to detect abnormalities that exist or will arise in the pregnancy are quickly identified and can be addressed immediately before affecting the pregnancy by conducting antenatal care checks [(5)].

The results show that the respondents who did a complete antenatal care visit were as much as 91.6% while the respondents who did not make a complete antenatal visit were 8.4%. The results of the study show that most respondents were aware of the importance of maintaining pregnancy [(6)].

According to the Indonesian Ministry of Health (2012), ANC visits of pregnant women are influenced by several factors [(7)]. The factors are including internal factors such as parity, mother's age and also external factors such as mother's knowledge, attitudes, socioeconomic conditions, socio-cultural, geographical, information and also the support from both staff and family[(8)].

The results show that the majority of respondents with a percentage of 91.6% made a complete ANC visit, the respondents who gave exclusive breastfeeding by 9.1% and while the respondents who gave non-exclusive breastfeeding were at 90.9%. This study was in line with a research conducted by Suparmi and Ika (2012) which stated that ANC visits affect the increase in the scope of exclusive breastfeeding [(9)].

Postnatal Care Factor on Breastfeeding Pattern: Postnatal care is a series of treatments performed for postpartum mothers including massages, breast care, oxytocin massage, postpartum spa and so on. Postnatal care is done so that the puerperal mother can pass through the puerperium phase well without any complications [(10)]

The purpose of the postnatal care visit is to take care of the health of both mother and baby, both physical and psychological, to treat the patient if any complications occur, provide health education regarding self-health care, nutrition, breastfeeding, provide information to the baby and care for healthy babies and providing family planning services [(11)].

The results show that the respondents who routinely visited postnatal care once were 8.3%, while those who did postnatal care visit twice were 60.4% and the respondents who visited postnatal care three times amounted to 31.3%. The distribution of PNC visits is positively related to the pattern of breastfeeding. Most respondents with a total of 86.2% with the frequency of PNC visits as much as twice decided to do the breastfeeding with a non-exclusive pattern.

The results show that postnatal care visits affect the pattern of breastfeeding. This study was in line with the research conducted by Seid et.al (2013) in Bahir Dar City Administration, Northwest Ethiopia which stated that there was a relationship between the amount of PNC visits with the exclusive pattern of breastfeeding [(12)]

Early Initiation of Breastfeeding (EIB) Factor on Breastfeeding Pattern: Early Initiation of Breastfeeding (EIB) which stands for early initiation of breastfeeding, is the baby's active effort to suckle within the first hour of birth, both normal and cesarean deliveries. The baby is placed on the mother's abdomen and chest immediately after birth and given the opportunity to start breastfeeding herself or himself by crawling for beasts and letting the baby's skin contact with her mother for an hour. On the first hour, the baby finds his mother's breasts in the beginning of a "life-sustaining between mother and child." The World Health Organization (WHO) recommended early breastfeeding to be initiated within the first hour after the baby is born by placing the baby in the mother's chest as soon as the baby is out of the birth canal[(13)].

The results of this study indicate that respondents who did an EIB were as many as 91.7%, while the respondents who did not do the EIB were 8.3%. In conclusion, most mothers have understood the importance of EIB for babies. The analysis shows that EIB has a big influence on the pattern of breastfeeding. This study was in line with the study of Pongtuluran, et.al (2017) who stated that there is a relationship between EIB and exclusive breastfeeding patterns [(14)].

Conclusion

During their pregnancy, majority of mothers make complete antenatal care visits with a frequency of 10 times, antenatal care is very important for mothers, especially the pattern of breastfeeding. In addition to the importance of antenatal care visits, mothers who have given birth and are entering the postnatal care phase are required to make postnatal care visits. Most of the mothers did a two times postnatal care visit and the postnatal care visit in this study had a major influence on the pattern of breastfeeding.

The coverage of mothers who initiate breastfeeding early in their babies after birth (EIB) can also be categorized as good. Therefore, the early initiation of breastfeeding has an influence on the pattern of breastfeeding.

Suggestion: For couples who are going to get married are required to take counseling at a public health center or a hospital to educate themselves regarding the preparation that will be done after marriage and after they have children. Counseling can also increase the mother's knowledge, one of which is the importance of breastfeeding for infants. In addition, health workers also provide education on how to treat breast nipples and injured breasts during breastfeeding.

Applying Strict Liability for Environmental Offenses: Indonesian Perspective

Al Halim

Student of Law Doctorat Program Diponegoro University, Indonesia.

Abstract

This study aims to analyze the rationality and application of strict liability for environmental offenses in the Environmental Protection and Management Act of Indonesia. The strict liability set out in this law expressly applies only to civil cases and covers the possibility that it may be used in criminal matters. Normative legal research complemented by a statutory and conceptual approach was used. The results showed that it generally applies to regulatory offenses aimed at protecting the public interest. This doctrine is necessary to improve the long-term and prevents harm to people or the environment. The absence of mental element proof should be limited to offenses that are characterized by the administrative dependence of criminal law, which is reflected in the abstract and concrete endangerment models. Generally, prohibited behavior related to waste/emissions disposed into the environment without approval causes damage. The offense is formulated as formal offense by eliminating the element of the perpetrator's culpability, and it is therefore not necessary to prove it.

Keywords: *Strict liability, Regulatory offenses, Administrative dependent of criminal law, Environmental harm.*

Introduction

Generally, a crime consists of both physical and mental elements. The first is characterized by active (commission) or passive actions (omission), the way they are performed, the consequences that cause damage, and the circumstances associated with the execution of prohibited actions.[1] The second refers to culpability of the actors that take various forms in an offense formula such as intentionally, with intent, knowingly, willfully, recklessly, or with criminal negligence.[2] This mental element can only be directed towards actions and their consequences which is obtained in most Modern Criminal Code. In its development, mental elements are not required in imposing criminal sanctions. In certain cases based on the concept of strict liability, the defendant can even be held liable and convicted of an act committed without the need of proving guilty.[3]

Furthermore, it is often associated with public welfare offense (regulatory offenses) which eliminates the element of perpetrators' fault to protect the public from avoiding danger. However, this concept is characterized by mild criminal threats, low community stigma, and generally includes arrangements related to industry activities.[4] Precisely, there are eight types of criminal activities including regulatory offenses, such as a) illegal sales of intoxicating liquor, b) sales of impure or adulterated food or drugs c) sales of misbranded articles, d) violations of anti-narcotics acts, e) criminal nuisances (consisting of annoyances or injuries to public health, safety, repose or comfort, obstructions of highways), f) violations of traffic regulations, g) violations of motor-vehicle laws, and h) violations of general police regulations, passed for the safety, health, or well-being of the community.[5] This study analyzes the application of strict liability in environmental crime. This is important because its provision in Law Number 32 Year 2009 concerning Environmental Protection and Management Act (EPMA) only applies to civil cases as formulated in Article 88. Meanwhile, most of the offenses against this law are essentially an administrative violation which in the formulation does not include a mental element of crime.[6]

The first part of this study explores the theoretical concept of strict liability in criminal law. However, not

all experts agree to apply it but can still be used for certain criminal acts. The second part explains the reasons for its application in environmental offenses, which requires intertwining between administrative and criminal law.[7] Most of them are also related to administrative violations such as permits.

The last part analyzes the application of strict liability to environmental offenses. The research argues that the concept of *res ipsa loquitor* (the thing speaks for its self) is inadequate to serve as a basis for applying it to environmental offenses. However, the EPMA includes an intentional element that was formulated materially. Therefore, the study offers a strict liability implementation in the context of the criminalization models based on environmental harms, especially abstract and concrete endangerment. In both models, violations threatened by criminal sanctions are generally related to administrative infringmentsince it does not require damages.

Method

This study is a normative legal study that focuses on the application of strict liability for environmental offenses in EPMA. The offense formulation in the Act is reviewed and selected following its regulatory character since the mental element has the potential not to be proven. Therefore, this study is complemented by the use of a statutory and conceptual approach, of which the first shows legal norms that contain the offense formulation. However, to know which offenses do not require proof of perpetrators, the strict liability doctrine and criminalization-based environmental loss models should be examined, especially abstract and concrete endangerment. Furthermore, legal issues in studies are analyzed qualitatively through data reduction, presentation, and conclusions used simultaneously.

Results and Discussion

The Nature of Strict Liability: Strict liability does not need to prove the perpetrator's culpability against one or more of the *actus reus*[8] since it is no longer considered as partial or total crimes. However, the fact that a commission or an omission offense has been committed needs to be proven. Within the criminal law, it is used for crimes that do not require the perpetrator's fault or a mental element following its occurrence.[9]

L.B. Curzon argues that there are several reasons why this element should not be proven since ensuring respect for the rules guiding the good of the community is important. Therefore, proving the existence of criminal action *(mens rea)* will be difficult for violations related to social welfare due to the high level of danger posed by the act in question.[10] There are many factors of the legislators which determine the use of strict liability in criminal law, because of, (1) characteristics of a crime, (2) threatened punishment, (3) the absence of social sanctions (*obloquy*) (4) certain damage caused, (5) scope of activities performed, and (6) the formulation of certain verses and their context in law.[11] These six factors demonstrate the importance of public concern in behaviors that need to be avoided by applying strict liability to public safety, the environment, and economic interests, including consumer protection.

Strict liability is most often used for public welfare offenses where criminal sanctions are generally mild such as fines and short imprisonment.[12] It is applied when the court concludes that the evidence of the action element leads to a definitive conclusion of finding it hard to prove the perpetrator's culpability. However, in cases related to violations of public welfare or regulatory offenses, the difficulty in proving is the basis for justifying the application of strict liability, in addition to the fact that the violated act is under public rules that have serious threats to health and safety.[13]

The doctrine of the public welfare offense was formed during the industrial revolution to impose tougher obligations on industry, commerce, property, or other activities that have an impact on public health, safety, and welfare. Strict liability requires two driving factors to improve the implementation of regulatory offenses. First, individual fault-proof requirements will weaken the burden of the criminal justice system. Second, in many violations of regulatory offenses, the fault-proof is quite difficult. Since the existence of some new types of criminal acts is not intentionally required, legislators begin to criminalize regulatory offenses although limited to certain areas.[14]

Strict liability is based on three objectives. First, social objectives such as healthy and clean food and drinks, surviving fires, workplace safety as well as in traffic orientation. Second, they can be better achieved through the types of criminal acts that do not require to prove the perpetrator's culpability to maximize social prevention. Third, strict liability is assumed only based on utilitarianism, when the criminal threat for a corresponding crime is low.[15]

One of the goals of criminal law is to prevent loss in society. The criminal justice system seeks to convict perpetrators that socially violate the 'normal' behavior.[16] In this context, strict liability is primarily based on the utilitarianism argument of promoting effective regulation of activities in various public and important places.[17] Furthermore, it causes people to be more careful in their behavior to prevent the effect of (one's) actions in the future. It also creates a high standard of public behavior in the hope that the public will show increased responsibility and behave more cautiously in certain areas. Therefore, it can prevent harm to others or property.[18]

Not all experts agree that strict liability is used in criminal cases with the reason that they do not require the perpetrators' mistakes proof since they cause controversy.[19] In addition, it violates the fundamental principles of criminal law, where the imposition of its sanctions is only valid when the defendant's mistake has been proven.[20] Therefore, even though strict liability will be applied in criminal cases, it should be limited only to offenses in the *malum prohibitum* category, because the evil nature of an act is not inherent, solely because the law prohibits.[21]

Rationale for Stict Liability: Strict liability is regularly used in the environmental offense, and this is justified by several reasons. This offense can lead to long term dangers and they are difficult to repair directly or indirectly. This danger shifts the focus from protecting individual to public interests. However, the use of strict liability in this context only transfer full responsibility of the hazard to people that can prevent the loss.[22]

Hazardous and toxic waste (B3) discharged into the environment without authorization can potentially have uncontrolled effects with B3 migration below the surface. It harms human health and the environment. The application of strict liability is justified because unauthorized storage and disposal of B3 waste, regardless of the precautions taken, can lead to enormous environmental losses in the form of water pollution.[23] The absolute responsibility to think and have knowledge of these actions can potentially harm others or the environment, such as damage and degradation of ecosystems, species extinction, climate change, and global warming, environmental pollution, as well as the increased mortality rate in animals.[24] B3 waste discharged into the environment through safety procedures and processes also increases the incidence of respiratory illnesses and reduces the overall quality of the earth's atmosphere. The impact can be felt long after the perpetrators dispose these materials.[25]

Strict liability on environmental offenses is also based on the argument that the legal interests to be protected are not only humans and the environment but also future generations. The current generation does have full control over all the natural resources on earth. However, the right of future generations to have equal rights and access to healthy environmental quality should not be compromised.[26] Meanwhile, the environment is also considered as an independent legal interest since it is a victim of crime,[27] therefore, humans need to obey nature (the environment).[28]

The offenses in the EPMA are mostly related to violations of administrative obligations such as authorization. Therefore, it depends on fulfilling the conditions set by or the provisions contained in administrative regulations set out in Articles 100, 101, 102, 103, 104, 109, 110, 111, and 114. The offenses are categorized as administrative dependent crimes for three reasons. First, it is a formal offense that focuses on the prohibited acts, and not the consequences. Second, the prohibited actions are not shameful, but because they are prohibited by law (legally wrong). Third, the essence of offense in this study relates to violation permits for authorization. Therefore, the administrative nuance is thicker since some requirements need to be fulfilled prior to performing certain actions. Violations of these requirements are categorized as criminal offenses.[29]

Mental/mistakes elements were not explicitly stated in the offenses formulation, and they are considered to be proven by the prohibited acts. Therefore, there is no obligation for the public prosecutor to prove the mental element. Its absence in the strict liability context requires everyone including corporations to be more careful in performing actions that can endanger the environment.[30]

Applying Strict Liability for Environmental Offenses: Environmental offenses stipulated in the EPMA consist of formal and material kinds. Formal offenses are regulated from Articles 100 to 111 and from Articles 113 to 115, and they are mostly administrative-dependent. On the contrary, material offenses are regulated in Articles 98, 99, and 112. The criminal law in the first two articles has been separated from the administrative independence of environmental criminal law. When the perpetrator's actions have caused

environmental damage or pollution, criminal sanctions can be imposed immediately even though they are not against the law.

Strict liability can be applied to formal offenses with substance in the form of administrative's violation requirements such as a permit/license. However, its implementation in material offenses will cause some problems. In many cases, environmental damage or pollution only occurs long after the prohibited acts have been committed. It is very difficult to prove the causal relationship (causality) in environmental cases because they are varied, chained, and complex as well as involving many variables especially in pollution.[31]The criminal threat in material offenses at the EPMA is also very severe in the form of imprisonment years of at least 5 and at most 15 as well as fines of at least 5 billion and a maximum of 15 billion. The severity of this criminal threat contradicts the strict liability character that mostly related to regulatory offenses.

According to the study, its implementation needs to pay attention to the criminalization models-based on environmental harm, especially the abstract and concrete endangerment models since they do not require to prove culpability of the actors. The prohibited actions on both models are all formulated as formal offenses, while the substance is in the form of administrative requirements' violation. The first model criminalizes offenses towards administrative obligations. The criminal law is enforced immediately after violating an administrative law sequel to the occurrence of a real loss or threat of violation. This model restricts criminal acts without involving direct contact between contaminated material and the environment.[32]

Environmental offenses of the first model include 'conducting business activities (UKL-UPL) without having an environmental permit in Article 109', 'preparing EIA without having a competency certificate of its compiler in Article 110', and 'issuing an environmental permit without being equipped with UKL-UPL (Environmental Management Efforts (UKL) and Environmental Monitoring Efforts (UPL)) or issuing a business authorization without being equipped with an environmental permit in Article 111 '. However, the offenses without involving direct contact between contaminated material and the environment do not require proof of loss threat.

The second model does not require proof of actual loss, but sufficient in proving the threat of loss and actions performed unlawfully.[33] Criminalization in this model is performed to prevent the loss of both humans and the environment.[34]Therefore, this model emphasizes that emissions or pollution can cause damage and need to be proven since they are performed unlawfully. As long as the administrative regulations are followed, the law is not considered a criminal offense when it is legally enforced. In contrast, it is qualified as a crime when committed illegally.[35] Furthermore, it directly protects ecological values, but its existence depends on administrative regulations.[36]

The offenses in the second model criteria include 'releasing and distributing genetic engineering products to environmental media that contradict the permit in Article 101', 'violating the wastewater and emission-quality standard in Article 100', 'conducts B3 waste management without permission in Article 102', 'produces B3 waste and does not conduct management in Article 103', and dumps waste material into the environmental media without permission in Article 104'. These offenses relate to direct contact between the contaminated material and the environment. Furthermore, there is evidence that actions are performed against the law and threaten environmental damage/pollution.

Strict liability can be applied to these offenses considering that they have been formulated as formal offense that do not require the causation. The absence of a criminal offense also depends on administrative requirements. Therefore, the administrative nuance is very thick with regulatory offenses, and it does not include mental elements such as intention or negligence. In addition, the defendant can be convicted when proven guilty of prohibited acts without authorization. The method of formulating prohibited acts also shows that the intentions of the perpetrators already exist when they commit them. Although, it does not need to be proven, such as managing B3 waste, and dumping it to environmental media without permission. These actions are generally performed by corporations since they have the potential to harm both humans and the environment.

Conclusion

Strict liability is often used in offenses aimed at protecting public interests which endanger human safety/health and the environment. The use of this doctrine on environmental offenses correlates with its position as an independent legal interest that prioritizes the prevention of hazards. Also, the implementation of

strict liability needs to be limited in the EPMA only to offenses dependent on the criminal law as in the abstract and concrete endangerment models. Their offenses are generally related to waste/emissions discharged into the environmental media without permission. They are also formulated as formal offenses, where the perpetrators' mental element is not included in the formula. Therefore, it does not need to be proven.

Investigation of Cutaneous Leishmaniasis Cases in Baghdad Province, Iraq

Aliaa F.A. Al-Naimy[1], Ali B.M. Al-Waaly[1]

[1]Scholar Researchers, Department of Biology, College of Science, University of Al Qadisiyah, Iraq

Abstract

444 cases were recorded of cutaneous leishmaniasis in Baghdad General Hospitals and some private clinics in Baghdad city and reviewed during the period from 1/10/2019 until 5/2020. The lesions were clinically diagnosed by dermatologists. Where the highest incidence was among males compared to females, it was found that the age group of (1-10) and (10-20) is the highest injury and that the rest of the age groups showed a decline. It was clear that the lowest percentage was among (50-60 yrs) patients, and the highest injury among the youth category. The rate of infection was higher in rural and agricultural areas compared to the city center. The infection rates in relation to different body sites are the highest in the upper extremities compared to the lower extremities. And according to the ulcer number, the multiple types were more than the single ulcers, and regarding the time of infection the highest rates of infection appear in December and February compared to the rest of the year.

Keywords: *Cutaneous Leishmaniasis, Leishmania tropica, major, Leishmania epidemiology.*

Introduction

Cutaneous leishmaniasis is a transmited disease caused by multiple types of leishmania, and it represents a public health problem in society and a danger to people who travel or live in endemic areas(1). About 12 million people are infected in 98 countries with these diseases, with 350 million people are at risk of infection(2). Parasites are transmitted through the bite of the sand fly female, of the genus *Phlebotomus* in the Old World or the genus *Lutzomyia*(3). Approximately 100-1000 promastigotes are infected into the skin as they are invaded by the neutrophils that spread rapidly at the site of the sting(4). The total number of reported cases of leishmaniasis in the period from 2008 to 2015 in Iraq reached 17001 cases ranging between 2.9-10.5/100,000 people(5). Aim of this study to determine investigation of cutaneous Leishmaniasis cases in Baghdad province, Iraq.

Materials and Method

Study Area: Baghdad is the capital of the Republic of Iraq, and it is in the Tigris Plain Valley in central Iraq, about 39 meters above sea level, between latitudes 33 north and 44 east. Its climate is generally hot. The rainfall rate is 100-175 each year, 58 between November and March. Average temperatures reach 50° C during the summer, and according to(6) the average high temperature is 15.5 ° C (January) to 44°C (July), and the average low temperature is 3.8°C (January) to 25.5°C (July).

Sample Collection: The epidemiological study was conducted on 444 patients suffering from skin lesions of different ages and genders that were diagnosed by dermatologists as leishmaniasis for the people who came to the hospitals of Baghdad, which were included in the study and for the period from 1st October 2019 until May 2020.

Diagnosis of Samples:

Clinical Diagnosis: Clinical diagnosis was made by a dermatologist.

Laboratory Diagnosis: Used direct smear method prepared from the edge of the ulcer and stained using Giemsa then checked for amastigotes by high–power microscope with oil immersion.

Statistical Analysis: The data was analyzed using SPSS statistic software version 25.Chi-square test was used for the assessment of association among the variables studied. The p-value of less than 0.05 was statistically significant, and highly significant for p-value of less than 0.001[7].

Results

1. **Percentage of people with cutaneous leishmaniasis, by sex:** The highest infection rate for males was 55.6% compared to females at 44.4%, as shown in Table (1). The results of the statistical analysis using Chi-square were used, and there was a significant difference between the infection of cutaneous leishmaniasis and its relationship to gender under the probability level 0.05.

Table (1): Shows percentages of people with cutaneous leishmaniasis by gender.

Sex	No. of infection	Percentage
Male	247	55.6
Female	197	44.4
X^2	11.26	
P value	P 0.001(HS)	

HS: Highly significant difference (P <0.01)

2. **Percentage of patients with cutaneous leishmaniasis, by age:**

The proportions of infection with cutaneous leishmaniasis parasite were calculated based on the age groups, where it was found that the age group of (1-10) and (10-20) have the highest infection rate, reaching (32.0%) and (36.0 %), respectively, and that the rest of the age groups showed a clear decline, and the lowest percentage among (50-60 yrs) was (1.0%), as shown in table (2). The results of the statistical analysis using the Chi-square showed that there were significant differences without infection with cutaneous leishmaniasis and age groups below the probability level 0.05.

Table (2) Shows the percentages of people with cutaneous leishmaniasis by age

Age group	No. of infected	Percentage
10 >	142	32.00
10 – 20	160	36.00
20 – 30	67	15.00
30 – 40	62	14.00
40 – 50	9	2.00
< 50	5	1.00
Total	444	100
X2	344.41	
P value	P <0.0001(HS)	

HS: Highly significant difference (P <0.01)

3. **Percentage of patients with cutaneous leishmaniasis, according to the location of the residence:** The rates of infection with cutaneous leishmaniasis parasite, according to the location of housing during the current study period showed that the rates of infection increased in Rural areas by (39.0%), followed by agricultural areas in the city by (27.0%) while the remaining infection rate was in the center of the city urban areas and has shown a decline in injury rates, as shown in Table 3. The results of the statistical analysis using the Chi-square showed significant differences. The prevalence of cutaneous leishmaniasis in the districts, poor areas, and the city center is below the probability level 0.05.

Table (3) Shows the percentage of people with cutaneous leishmaniasis, according to the location of the residence.

Region	No. of Infected p. ts	Percentage
Assadr	174	39.00
Mahmudiyah	120	27.00
Hosseinieh	59	13.00
Alkaramah	63	14.00
Adhamiya	28	7.00
Total	444	100.0
X^2	189.79	
P value	P < 0.0001(HS)	

HS: Highly significant difference (P <0.01)

4. **Parasitic infection percentages according to the site of infection from the body:** The rates

of infection in the hands and feet sites are among the areas most affected by parasitic ulcers (60.0%) compared to the face (25.0%). The lowest incidence of ulcer was the back site (2.0%), as shown in Table 4. The results of the statistical analysis using the Chi-square showed significant differences. Infection with cutaneous leishmaniasis and its distribution to different areas of the body under the probability level of 0.05.

Table (4): Shows the percentage of parasitic infection according to the site of infection from the body.

Infection site	Number	Percentage
Face	210	25.00
Neck	81	10.00
Chest	26	3.00
Back	22	2.00
Hand	299	36.00
Foot	198	24.00
Total	836	100.0
X^2	550.7	
P value	P <0.0001(HS)	

HS: Highly significant difference (P < 0.01)

Discussion

Distribution of cutaneous leishmaniasis by gender: The results of the statistical analysis of the relationship between cutaneous leishmaniasis and the host's sex showed that males had a higher rate of infection than females with a rate of 55.6% and 44.4%, respectively. It may be attributed to the fact that males are more exposed to infected vectors than females. Arroub *et al*[8] stated that males who work or sleep in the open and rooftop areas with less body coverage are more susceptible than others. Some studies have assumed that the sex difference observed in some parasitic diseases can be attributed to hormonal influences, but the role of sex hormones in the immune response remains controversial[9,10,11]. The current study agreed with Mohammad & Al-Khaliq[12] in Baghdad governorate, where it recorded the highest rates of infection in males with a rate of (65%) compared to (35%) of females. The study also agreed with Salman *et al*. [13], where the highest percentage of males was recorded at 56 and (82.35%) more than females whose number of injuries exceeded 12 and by (17.64%). It agrees with Al-Khayyat et al., [14] in the governorate of Baghdad, where it recorded the highest rates of infection in males by (60.3%) compared to females by (39.6%). The study differed with Kattoof, [15] in Baghdad Governorate, where it recorded the highest rate of infection among females, as it reached (24%) in comparison with males (21%). It also differed with what Alawieh *et al* [16] in his studies in Syria, where he recorded the highest percentage of females (52%) compared to females (48.9%).

Distribution of cutaneous leishmaniasis by age: The current study showed that the highest incidence of cutaneous leishmaniasis is between (10-20) years, with a rate of (36%), and the lowest in the age group (5-60) years with a rate of (2%). Significantly due to the external activities of young people more than other age groups where young people are often ill [17]. The low incidence of cutaneous leishmaniasis for older adults may be related to the fact that they were infected during the early ages and acquired long-term immunity during Childhood[9,10,18]. The current study agrees with[12], which recorded the highest incidence of cutaneous leishmaniasis in the age groups between 5-24 years more than others (67.5%). The current study differs with Al-Mafraji *et al*.,[19] in Baghdad governorate, where the highest rates of infection were recorded for ages under 30 years of age from the youth category (42.6%). The study differed with Al-Mayali & Al-Hassani,[3] in Diwaniyah governorate, where the highest incidence of cutaneous leishmaniasis was recorded for less than 5 years of age group 34.7%.

Distribution of cutaneous leishmaniasis according to residence: The obtained results showed that the rates of infection increased in the agricultural areas, districts, and poor neighborhoods, where they increased in Sadr City by 39%, followed by the Mahmudiyah District by 27% and the lowest in the Adhamiya region by 7%, attributed to the increase in the highest rates of infection in the agricultural and districts And slum areas due to the abundance of poor hosts that store the disease, which leads to an increase in the chances of infection with the parasite throughout the year, and it increases especially in agricultural areas due to the continuous cultivation of it in all seasons of the year, while this percentage decreases in urban areas.[9,20]. The study agreed with Kashkool,[21] reported the highest infection rates in rural and agricultural areas, reaching 317 (92.4%), and the lowest injury was recorded in urban areas, reaching 26 (7.6%). The current study also agreed with Al-Mashhadany,[22]; Al-Mayali & Al-Hassani,[3]; Khudhur,[23] they recorded

the highest rates of infection in agricultural and rural areas and the lowest infection in urban areas. They also agree with Reda,[12] in Babel governorate, where the highest rates of infection were recorded in agricultural regions with a rate of (55%) followed by the districts with (25%) and the lowest percentage in the city center with a rate of (20%). The study differed with Kattoof,[15] in Baghdad governorate, where the highest rate of infection was recorded in urban areas, at a rate of (28%), compared to rural areas and poor neighborhoods, at a rate of (18%). The study also came different with what Luma[24] found In the city of Babel, where the highest incidence of cutaneous leishmaniasis in urban areas was 32 (53.3%) more than in rural areas 28 (46.7%).

Conclusions

The Leishmania parasite infects both sexes and all ages without exception and the highest incidence was for young people, and infection were also recorded that the highest incidence was in January and February, while multiple ulcers occupied the largest proportion of ulcers and the most affected sites were the hand and face compared to different body sites. The city of Baghdad is one of the cities where cutaneous leishmaniasis is endemic, as infection varies according to the difference in regions.

To Compare the Effects of Footwear in Young Female's Postural Balance in Prolonged Standing and Sitting Job

Anandita Sharma[1], Yamini Sharma[2], Megha Yadav[2], Mangalam Kumari[2], Jyoti Sharma[2], Sakshi Arora[2], Akshay Anand[3]

[1]Student Researcher, BPT Galgotias University, Greater Noida, India, [2]Assistant Professor, Galgotias University, Greater Noida, India, [3]Assistant Professor, Manav Rachna International University, Faridabad, India

Abstract

Background: Footwear has an essential role in raising well-being of any person. Many females have wear heel or flat footwear on their daily basis as if they are working or not. Footwear creates discomfort which leads to pain in foot, and results in alteration of balance. Most of the working places requires prolonged period of standing which is possibly associated with musculoskeletal disorders,likely affects our health and acute trauma from the working places. Prolonged sitting and standing can directly affect the weight-bearing joints majorly the hip, knee and ankle joint which in turn leads to deformities and effects balance. Changes in this composite system results in the risk of falls and loss of stability.

Objective: The objective of the study was to identify the effects of footwear in young female's postural balance in prolonged standing and sitting job.

Materials and Method: 100 healthy females were taken for the study age 18-35 years but only 60 were selected for the study. The subject had to perform Rhomberg test and tandem walk for balance assessment.

Result: On analysis, it was found that in rhomberg balance test, 73.33% population were positive with the test. 8.33% population were positive with the eyes opened and 65% population were positive with the eyes closed and in tandem walk, 31.66% population is positive who were unable to complete the test.

Conclusion: In conclusion, the balance tests shows that, wearing footwear for prolonged hours of standing and sitting job,states that the balance and postural control worsening which is associated with decrease in postural stability and increase in the risk of falls.. According to the study balance is more effected in prolonged sitting than in prolonged standing.

Keywords: *Balance, postural control.*

Introduction

There are many different professions in our country in which females are working. Some have sitting jobs (co-operative jobs,) and other have standing jobs (female guards, CRPF females, female traffic police job etc). During long hours of job, women prefer footwear which are more comfortable in standing as well as in sitting. Footwear are considered by the women as an essential part of their regular outfit. There are different types of fancy footwear females have wear to appear good and this also enhances their personality.

With generality of 39% noticed in institutional settings and 78% of generality noticed in clinical settings which showed a massive ratio of female population and with this usage of different heels and flat footwear leading to alterations in the person postural balance.

There was a survey conducted by the hotter shoes which suggested that to look attractive women goes to such extent that they wear different heels which extremely very high which are leading to problems such as sore foot and tired foot because of wearing them whole day.[1] Murphy et al. had recommended that footwear were the key component in the building of human posture.[2]

Footwear has an essential role in raising well-being of any person.[3] As footwear passes the sensory information to the foot, and a person can control the postural stability through the touch and proprioception.[4,5]Footwear creates discomfort which leads to pain in foot, and results in alteration of balance.

Balance can be defined as a situation in which one's body dynamics are proportionate just to prevent the person's body from falling and also the ability to uphold, attain and reinstate the person's body center of mass (COM) respective to the base of support (BOS). Maintaining balance is acknowledged as keeping the center of gravity (COG) in BOS defined by the feet.[7]Balance is sustained through dynamic combination of internal and external.[8] Functional activity and motion is necessary for balance. Functional balance is capability of an individual to maintain a position and posture during any functional motion.[2]

Postural control or balance can be defined statically as the ability to maintain a base of support with minimal movement and dynamically as the ability to perform a task while maintaining a stable position.[10]

The aim of the study is to determine the effects of footwear on young female's postural balance in prolonged standing and sitting job. Many researches have been done on effects of footwear on balance but this research will leads to explain the how footwear effects the balance in prolonged standing and sitting job. For static balance test, rhomberg berg test has been done and for dynamic balance test, tandem walk has been done.

Prolonged period of working is defined as standing and sitting for 50 percent of the working day or more of it.[11] Most of the working places requires prolonged period of standing which is possibly associated with musculoskeletal disorders,likely affects our health and acute trauma from the working places. Most of the interviews disclosed excessive proportion of musculoskeletal discomfort and environmental demands and other chronic problems.[12] Neck and trunk flexion in prolonged standing in day to day life is the threat which causing skeletal disorders and it can lead to various problems in legs and feet such as discomfort, fatigue and pain in neck, lower back, hip, spinal compression, chronic venous insufficiency. It also increases risk of heart attack, swelling due to impaired circulation and decreases the oxygenation and nutrients supply leads to muscle fatigue.[1]

Static postures such as prolonged sitting and prolonged standing increase physical and mental exertion on the body and these exertions increases the force on the musculoskeletal system.[13] Disuse of muscles by prolongedsitting can cause weakness of muscles. Prolonged sitting can lead to ischemia, apoptosis (programmed cell death), it may directly affect the musculoskeletal system [13] like pain in legs,[16] chronic venous insufficiency,[18]spinal compression,[15] and impaired circulation which in result causes swelling of the lower extremities.[13,14.] During standing in one position or maintaining the erect posture without an ease of walking rhythmically, affects the blood circulation and compromised body fluids.[13] This causes swelling and pooling in lower extremities.[13,14]

Prolonged sitting and standing can directly affect the weight-bearing joints majorly the hip, knee and the ankle joint which in turn leads to deformities and effects balance. Changes in this composite system results in the risk of falls and loss of stability. [3] In maintaining the balance of the body which may be deformed both by intrinsic forces (body movement), and by the extrinsic forces (the forces which is acting on the body in a certain environment).[3]

There are many more researches based on balance but there is no research had been done on the effects of footwear on young female's postural balance in prolonged standing and sitting job. This research will provide the intra subject reliability of balance measurements in young females.

Material and Method

Study Area: This study was carried out from the various working places.

Study Design: This was an observational study.

Study Population: The study population consisted of 100 young females.

Study criteria:

Inclusion: Healthy female's (18-35years).

Exclusion: Any diagnosed history of recent muculoskeletal trauma, congenital anomalities, joint pain, neurological disorders.

Procedure:

1. **Rhomberg test:** In this test, the subject was asked to stand with the feet together and arms hanging alongside . The subject is instructed to stand for 30 seconds with eyes open and the postural sway was observed. Then we asked the subject to close her eyes The test is positive if sway or imbalance was there.
2. **Tandem walk:** The subject is instructed to fold their arms across their chest walk by placing one foot directly in front of the other, like heel-to-toe walking. Walking as fast as they could for 30 steps.[17] The test is positive if the subject cannot walk in heel to toe position or if the subject is disbalanced during the test.

Result

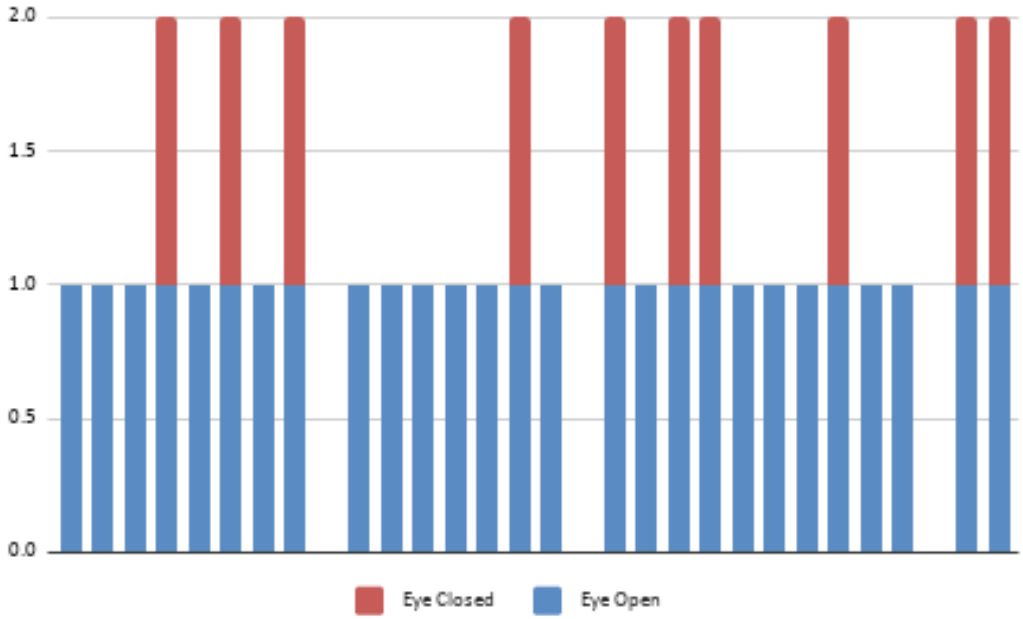
The total subjects taken for this study were 100 but only 60 were fit for the study and 40 subjects were excluded on the basis of exclusion criteria.

This is an observational study and there is some inclusion and exclusion criteria for the accuracy of the data which was collected from the subjects. The Balance tests which have been done to identify the static and the dynamic balance. Rhomberg test have been done with eyes open and close to identify the static balance. In Rhomberg test, 73.33% population were positive with the test. 8.33% population were positive with the eyes opened and 65% population were positive with the eyes closed. (Table 1).Tandem walk were used to observe the dynamic balance, 31.66% population is positive who were unable to complete the test. (Table 2).

Data:

Table 1: Rhomberg Test

Parameters	No. of subjects	Percentage (%)	Mean±Standard Deviation
1a. Eyes open			
No Sway Sway	55 5	91.66% 8.33%	0.9166 ± 0.2763
1b. Eyes closed			
No Sway Sway	21 39	35% 65%	0.35 ± 0.4769



Graph 1: Showing data of eye closed and eye open subjects.

The graph showed the percentage of the subjects sway or no sway during Rhomberg's eyes open and close test.

Table 2: Tandem walk

Parameters	No. of subjects	Percentage (%)	Mean±Standard Deviation
Positive test	19	31.66%	0.6833 ± 0.4561
Negative test	41	68.33%	

Table 2 This graphs showed the relation between the age and the test performed by the subjects.

Discussion

In this research, we have examined the effects of footwear on young female's postural balance in prolonged standing and sitting job by the balance test examination.

The static and dynamic balance is affected by the property of footwear which includes their materials, stiffness, and soles thickness, collar height and the coefficient of friction of the outer sole of the footwear.[19] Several earlier studies have been studied about relation of balance and The ability of static and dynamic balance due to wearing high heels and causes muscle fatigue.[20] Heterogeneity of footwear in young females and the females in their 20s prefer to wear low heeled casual footwear in spite of any motive or wants..[21] Another study examined that duration of wearing high heels in young adults revealed that the muscles such as rectus femoris and tibialis anterior did not indicate any such significant differences in lower extremities muscle activity and in static balance.[6]

Most of the studies have accomplished the effects of footwear on balance. Thus, the basis of this research was to the examined the effects of footwear in a specifically young aged female's postural balance. For prolonged standing and sitting causes musculoskeletal problems and other related problems like pain in legs, spinal compression, venous insufficiency, swelling.[1,13,14,15,16,] People should deliberate in their daily life about the types of shoes and the heel height.[2] The balance tests which have been done in this research studies states that the alteration in balance of females due to footwear is affected. The subjects when performing the tests were more dis-balanced in eyes closed task as compared in eyes open. And if we compare the test between the tandem walk and rhomberg's eyes open and close tests, the subjects having more difficulty in performing the rhomberg's eyes closed test. According to the results, females have to wear footwear according to their comfort ability and during prolonged hours of jobs in sitting and standing dynamics, they need to relax her foot in every hour in order to keep their foot relaxed and it will prevent from swelling, leg pain and other causes which we have discussed in our research study.

Limitation of Study:

- Less number of subjects.
- Less number of tests is used to assess balance.
- Heel height.
- Type of heels.
- We do not know that the subjects involve in any sports activities.
- We did not compare the subject's arches whether they are flat foot, pes cavus or normal.

Future Scope:

- It will help in the prevention, evaluation and treatment of primary and secondary structural damage in foot, and other musculoskeletal conditions.
- We only took the young women but with the inclusion of women of middle and old age, the generalisability will increase and we can have a better result.
- We had only compare the result between females, for further studies use comparative effects in males and females in prolonged working hours.

Conclusion

In conclusion, this study examined the effects of footwear in young females postural balance in prolonged standing and sitting job. The result showed the significant differences in rhomberg test. The subjects having difficulty during eyes closed test than in eyes open and in tandem walk test showed that the subjects

having difficulty in heel to toe walking because of having trouble in maintaining balance.

In the study the balance tests shows that, wearing footwear for prolonged hours of job, states that the balance and postural control worsening which is associated with decreases in the postural stability and increases in the risk of falls. According to the study, balance is more effected in prolonged sitting than in prolonged standing.

Prospective Studies on Pattern of Two Wheeler Injuries in Road Traffic Accidents

Arun Prakash K.S.[1], Sanjeev K.[2], Gambhir Singh O.[3]

[1]Assistant Professor, [2]Associate Professor, [3]Professor & HOD, Department of Forensic Medicine, SRM Medical College Hospital and Research Centre, Kattankulathur, Chennai–603 203

Abstract

It is a prospective study of fatal two wheelers accident cases brought at Indira Gandhi Government General Hospital & Post Graduate Institute, Puducherry. Amongst 118 cases, 79.66% were male whereas 20.33% were female. Highest numbers of victims were in the age group of 36-55 years, accounting for 45 (38.13%). There was a higher rate of head and neck injuries in the present study followed by head, neck & lower limb and head, neck & upper limb. Numbers of people who succumb to two wheeler accidents are on an increasing trend in India. Fatality rates among the people involved in RTA shows an alarming increase. It was observed that violating the traffic rules is found to be the major contributory factor and men and teenagers are the most common people involved in these accidents. Measures to prevent these accidents and decrease the mortality rates in these situations includes strict adherence to traffic rules.

Keywords: *Two wheelers, Road Traffic Accidents, Drunken Drive, Mechanical injuries.*

Introduction

Road traffic accidents are the only public health problem for which society and decision makers still accept death and disability among young people on a large scale[1]. India ranks 1st in the number of road accident deaths among 199 countries reported in the World Road Statistics, 2018 followed by China and the US. As per the WHO Global Report on Road Safety 2018, India accounts for almost 11% of the accident-related deaths in the World[2].

According to the National Crime Records Bureau (2010), the number of vehicular accidents was 430600 resulting in 133938 deaths and 470600 injuries, thereby accounting for 37.2% of all accidental deaths (3). A study was conducted for five years form 2000 -2004 to draw the pattern between the age, sex of the victim, type of injury, and their association with the road traffic accidents. As per the results a majority of 77% were in the age group from 18-44 years accounted for nearly 69.6 percent of road accident victims, the accident ratio was 83% in male whereas for the female it was 17%. They have also mentioned that 81% of the geared vehicles have been a part of the accidents that occurred (4). Tamil Nadu and Uttar Pradesh accounted for the highest number of road accidents and death in road accidents respectively in 2018, the report revealed (2).

Because, most of the national highways in India are made by tar and the fact is that the national highway is 24 hrs busiest roads with vehicles travelling at high speeds, the roads being less wider multiple intersections and divider cuts are present at every kilometre for changing the side.[3,4,5].

Though the facts of the motorcycle accidents are obvious no much attention is paid to it. The accidents by a motorbike is 27 times fatal than a caras by the source [5]. This does not imply that car accidents are less damaging but the impact and the numbers are greater on the comparison.

Method and Materials

The study is a prospective analysis of cases of fatal two wheelers accident autopsied at Indira Gandhi Government General Hospital & Post Graduate Institute, Puducherry during the period November 2013 through April 2015 after obtaining ethical clearance. Out of the total 159 cases of RTA we have chosen 118 cases where two wheelers were involved. External and internal postpartum findings were observed and recorded in the performa. History about the accident, the time, day, month, type of road, type of vehicle, were obtained from investigating officer and relatives of the deceased and were recorded in the Performa. The cases with incomplete details were not taken into consideration.

The data were analyzed with SPSS-20 software and the results were interpreted in terms of percentage, mean, chi-square, and z-test. Then we compared our findings with the works of other authors.

Observation: There were 118 fatal two wheelers accident cases out of the total 159 fatal road traffic accident dead cases. Age-wise, Sex-wise and other findings are displayed in Table No.1. Amongst 118 patients, 79.66% were male whereas 20.33% were female. Highest numbers of victims were in the age group of 36-55 years, accounting for 45 (38.13%) patients. On applying, Chi-square test, it is shown that the age group 36-55 years and above 55 years is statistically significant. Male are more vulnerable to two wheeler accidents than female. 98.30% of the patients got accident in Tar road than cement & Mud road.

Table No. 1: Age-Sex-Type of Road Involved

Age Group (Years)	Total	Sex		Type of Road		
		Male	Female	Tar Road	Cement Road	Mud Road
1-18 Years	4(3.38%)	4(3.38%)	0	3(2.54%)	1(0.84%)	0
19-35 Years	31(26.27%)	25(21.18%)	6(5.08%)	30(25.42%)	0	1(0.84%)
36-55 years	45(38.13%)*	35(29.66%)	10(8.47%)	45(38.13%)	0	0
Above 55 years	38(32.20%)*	30(25.42%)	8(6.77%)	38(32.20%)	0	0
Total	**118(100%)**	**94(79.66%)**	**24(20.33%)**	**116(98.30%)**	**1(0.84%)**	**1(0.84%)**

*Indicates P<0.01, that is significant

Table No. 2 shows distribution of cases according to manner of accident. In 36 cases, (36.50%) it was due to hitting against the pedestrian. In 25 cases, (21.23%) death were by collision with heavy passenger vehicle.

Table No. 2: Distribution of Cases According to Manner of Collision

History of Accident	Frequency	Percentage
2 wheeler hitting against the fixed object	12	10.16%
Fall from 2 wheeler	20	16.94%
2 wheeler hitting against the pedestrian	36	30.50%
2 wheeler vs 2 wheeler	9	7.62%
2 wheeler vs Heavy passenger vehicle	14	11.86%
2 wheeler vs Bicycle	4	3.38%
2 wheeler vs Heavy vehicle	11	9.32%
2 wheeler vs 4 wheeler	12	10.16%
Total	**118**	**100%**

Analysis of various injuries in the body of the victims revealed that the maximum number of patients got injured in the head & neckregion (25.42%) shown in Table No.3. Head & Neck and upper limb (9.32%), head & Neck and lower limb (11.01%), Head & neck and thorax (7.62%), head & Neck and upper limb (8.47%), Head & neck, abdomen and upper limb (8.47%), head & neck, abdomen and lower limb (10.16%), head & neck, thorax, pelvis and lower limb (6.77%), Head & Neck, Abdomen, Groin, Spine and Back (9.32%) and Head & Neck, Abdomen, Groin, Spine, Lower limb and Back (11.86%) were more predominantly injured area in the accident.

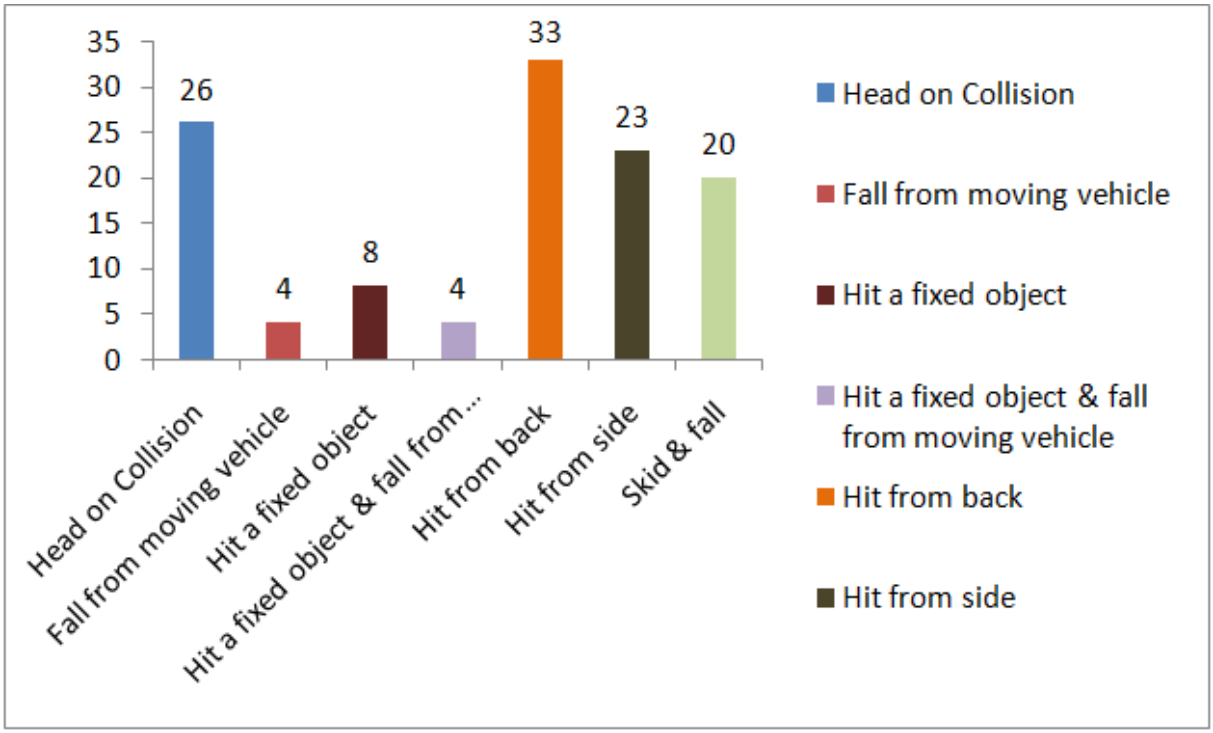

Figure 1: Bar Chart shows the distribution of type of accidents

Table No. 3: Distribution of Injured Body Surface

Site of Injury	Frequency	Percentage
Head & Neck	30	25.42%
Head & Neck and Upper limb	11	9.32%
Head & Neck and Lower limb	13	11.01%
Head & Neck and Thorax	9	7.62%
Head & Neck, Abdomen and Upper limb	10	8.47%
Head & Neck, Abdomen and Lower limb	12	10.16%
Head & Neck, Thorax, Pelvis and Lower limb	8	6.77%
Head & Neck, Abdomen, Groin, Spine and Back	11	9.32%
Head & Neck, Abdomen, Groin, Spine, Lower limb and Back	14	11.86%
Total	**118**	**100%**

Most common injuries observed were abrasion, laceration, sutured wound and contusion observed in all 118 cases. In that combination of abrasion & laceration (26.27%) is the most common type of injuries observed in the patients and followed by Abrasion, Abrasion & Sutured wound, Abrasion, Laceration, Sutured wound & Contusion were 19.49%, 16.94%, 14.40% respectively shown in Table No. 4.

Table No. 4: Cases Distribution According to Injury Type

Type of Injury	Frequency	Percentage
Contusion	6	5.08%
Abrasion	23	19.49%
Laceration	14	11.86%
Abrasion & Contusion	7	5.93%
Abrasion & Laceration	31	26.27%
Abrasion & Sutured wound	20	16.94%
Abrasion, Laceration, Sutured wound & Contusion	17	14.40%
Total	**118**	**100%**

As shown in figure 2, the injuries were commonly seen on the the face & lower limb 27(22.88%), followed by cerebral Lobes (21.18%), lobes, upper limb, lower limb & face (16.94%), cerebral lobes & lower limb (16.10%), upper limb & lower limb (16.10%). The less common area are lobes & upper limb (6.77%).

Discussion

Road traffic accidents are more common in a developing country like India. In this study, the majority of motor cyclist and pillion riders were adultsand in their most productive ages and showed a male preponderance. Present study is in consistent with the works of other authors[1.2,3,4].

The results of the present study revealed that 94 (79.66%) of the patients were males and the rest 24 (20.33%) were females. The highest number of patients 45 (38.13%) were from 36-55 years of age group. Among males, the maximum numberof cases were seen in the age group of 36-55 years 35 (29.66%) and above 55 years 30(25.42%). The mean age of the RTA victim came out to be 30.12yrs. However, other studies observed that mean age of the male victimized in road traffic accidents is 33 years.[6-11].

Due to high activity levels, participation in high-risk activities, reckless driving/riding, over-speeding and drunken driving, driving without wearing helmetsetc are main reason for high incidence rate among males. Similar observations were also reported by different authors[6-9]. On the other hand females due to social & cultural practice are less expose to road traffic accidents. Moreover, extra precautions taken by family members to keep them safe women have lesser possible to encounter road traffic accidents than male partners. Majority of these accidents occurred on the paved roads 116 (98.30%).

There was a higher rate of head and neck injuries in the present study followed by head, neck & lower limb and head, neck & upper limb. A possible explanation might be that two wheeler inhabitants did not use seat belts, resulting in forward jerk during a collision and higher rate of injury. Abrasions, lacerations, sutured wound and contusion were the commonest types of injuries among the external injuries noted in this study. Similar results were also observed by others researchers[12-16)]. Common sites for injuries were the lower and upper limbs and face[6,7].

Face & lower limb injury is more frequent in motor vehicle occupant 27(22.88%) followed by Lobes (21.18%), lobes, upper limb, lower limb & face (16.94%), lobes & lower limb (16.10%), upper limb & lower limb (16.10%). The less common area are lobes & upper limb (6.77%). It therefore, appears that motor vehicle occupant and motor cyclist were more vulnerable to the different type of injuries than other categories of the victims possibly due to a greater force of impact in the former and a longer distance of the fall in the latter[16,17] whereas the study conducted by Clark DW reported that more number of fractures appeared in the area of upper limbs, lower limbs and facial bones[18]. In line with our study Wong TW showed that commonest injury was fracture of bones particularly of the head and face and closely followed by the lower extremity[18,19].

Conclusion

The study highlights the pattern of injuries among the motor cyclists. By analyzing the various data that were published on RTAs and their major contributing factors, accidents are happening usually due to irresponsibility of the rivers. Hence, we recommend strict enforcement of the traffic rules and safety law for the motor cyclist like wearing the helmet, maintaining the speed limit etc. Moreover, advancement in technology of the wheelers has brought great advantages to the human but on the other hand the mishandling of these two-wheelers can even cause fatal death or injury. India has recorded the maximum number of deaths in two-wheeler accidents with a greater ratio of men being affected than the women because of not following the traffic laws Understanding the speed limit and obeying traffic laws could reduce the number of people affected by the accidents. It is high time that the policy makers should take a look at these

types of studies and do concerned modifications in the years to come.

A Review of Studies Assessing Cannabidiol's (CBD) Therapeutic Action and Potentials in Respiratory Diseases

Arwa Fairaq[1], Sahar El-Ashmony[1,2], Yosra AL-Hindi[1]

[1]Assistant Professor in Clinical Pharmacy, Faculty of Pharmacy, University of Umm Al-Qura, Makkah, KSA,
[2]Faculty of Medicine, Medical Pharmacology Department, Cairo University, Cairo, Egypt

Abstract

Cannabidiol (CBD) is the major non-mind-altering section of the hairy glands of hemp plant that can be named 'cannabinoids' (CBs). Cannabinoid in the pharmacology field is becoming an extensive subject specifically towards the therapeutic characteristics of cannabinoid receptor agonists. Examples such as analgesia, muscle relaxation, immunosuppressive, antiinflammatory and anti-allergic effects, mood improvement, appetite stimulation, antiemesis, lowering of intraocular pressure, bronchodilatation, neuroprotection, and anti-neoplastic effects. Although this vast knowledge about the therapeutic properties of CBs, their clinical uses remains a controversy and very limited. However, the focus now has been on CBD that constitutes up to 40% of the extract of the Cannabis and represents one of the most attractive prospects for therapeutic use owing to its extraordinary lack of both perceptual and psychoactive behavior. Finally, CBD is regarded as an important putative lead compound to produce cannabinomimetic drugs because of its excellent tolerability in humans.

Keywords: *CBD, Respiratory, pharmacology, review.*

Introduction

Cannabidiol: The terms *cannabis* and *marijuana* are frequently used interchangeably, but Cannabis is a generic term that includes cannabinoids, marijuana, and hemp-derived from the plant *Cannabis sativa*. The documented use of cannabis dates to several centuries BC[1]. The cannabis plant and its derivatives have been exploited for centuries for recreational and medicinal purposes, with millions of regular users around the world. Legislation around these purposes is increasingly considered by local, regional, and national governments[1]. Non-psychotropic Phyto-cannabinoid CBD is considered one of the most interesting emerging molecules in the field of pharmacology since it exerts a wide range of therapeutic effects, ranging from anticonvulsive, sedative, hypnotic, antipsychotic, anti-cancer, anti-inflammatory and neuroprotective activities[2].

More than 100 different cannabinoids have been identified, but delta-9-tetrahydrocannabinol (THC) is the most responsible fort he psychoactive effects of euphoria and relaxation. Cannabinoid 1 (CB1) receptors in the brain correlate with the psychoactive effects[3]. CBD is suggested to have therapeutic potential in many disorders, including inflammation, oxidative stress, cancer, diabetes, gastrointestinal disturbances, neurodegenerative disorders, and nociception[4,5]. Evidence is also now accumulating that there are beneficial effects of CBD in the vasculature. A review of the safety and side effects of CBD concluded that CBD appears to be well tolerated at high doses and with chronic use in humans, and thus has the potential to betaken safely into the clinic. Indeed, CBD is one of the active ingredients of the currently licensed medication, Sativex®[6].

CBD in some respiratory diseases:

Asthma and COPD: Asthma is a chronic inflammatory disorder of the airways with an increase in the bronchial hyperresponsiveness to different stimuli. Characterized by wheezing, breathlessness, chest tightness, cough, and reversible airflow obstruction[7]. Chronic obstructive pulmonary disease (COPD) is another respiratory disease that can be overlapped with asthma. COPD characterized by chronic airflow limitation, usually caused by significant exposure to noxious particles[7]. COPD, including Chronic Bronchitis and Emphysema, are Cause of death rank 4 with an expectation to increase in coming decades due to continued exposure to different COPD risk factors such as smoking, aging, and inactivity [8]. Treatments include bronchodilators, antimuscarinic agents, corticosteroids, and antiinflammatory medications are available. However, there is no cure for Asthma or COPD until now[9].

In the last decays, Cannabis, with its different content including Cannabidiol (CBD), draws attention as some studies show its variable pharmacological properties, including anti-inflammatory[10] immunomodulatory, and analgesic properties. Mechanistically via activation of cannabinoid-1 and −2 (CB1 and CB2) receptors presented predominantly in the central nervous system (CNS) and immune cells, respectively[10]. In immune cells, cannabinoids dysregulate cytokine leading to disruption of the immune system through[11]. Most studies explored the properties of Cannabis, but we're not focusing specifically on CBD. Therefore, further studies were conducted to explore the specific effect of CBD in lung disease. Studying genes related to respiratory disease COPD, Cannabis affected the expression of pro-inflammatory genes in human small airway epithelial cells (HSAEpC), in vitro[12].

In vivo, CBD (20 mg/kg) administration in lipopolysaccharide (LPS) induced lung injury murine and mice model decreased the migration of leukocyte into the lungs, albumin concentration in the bronchoalveolar lavage fluid, as well as production of pro-inflammatory cytokines (TNF and IL-6) and chemokines (MCP-1 and MIP-2) via adenosine A_{2A} receptor[13]. In an asthmatic rat model, CBD at the dose of 5mg/kg intraperitoneally (i.p) once daily significantly decreased inflammatory response by decreasing the level of both Th1 including TNF-α and IL-6 as well as Th2 cytokines including IL-3, IL-4, IL-5, IL-13 and IL-10 [13]. Furthermore, CBD treatment improved remodeling processes and reduced airway inflammation and fibrosis. Specifically, CBD decreased the collagen fiber content (CBD 5 or 10 mg/kg i.p.) and lung elastance (CBD 10 mg/kg i.p.) through CB1/CB2 signaling[14]. In addition, CBD improves pulmonary function as its administration associated with an increase in tidal volume, inspiratory flow rate, and respiration rate in the African Green Monkey model with induced pulmonary fibrosis [15].

The potential therapeutic effects of CBD in lung cancer: The searching to ameliorate the prognosis of lung cancer has led to the development and evaluation of new drugs with mechanisms of action that vary from those of conventional chemotherapeutics used for many years worldwide. A major attempt is now being placed in developing and assessing the potential of targeted therapies and immunotherapy in lung cancer that cause improvement in the clinical outcomes[16]. Thus, targeted therapy is replacing conventional chemotherapy as a standard treatment for patients with targetable oncogenic drivers[16]. However, it has to be recognized that responses to these agents are still partial, with tumors recurring during follow-up. In fact, due to tumors' genetic heterogeneity, a complete response in lung cancer patients is very difficult to attain[17]. The challenge to proceed with the outcome of patients with lung cancer is leading to the assessment of alternative drugs, which, alone or in combination, may lead to improved response and survival in patients. CBD is one possible example as it could be a potential drug in the treatment of cancer. CBD has been shown to have anti-neoplastic effects in vitro and/or in vivo in lung cancerand other types of cancer[17,18]. Newly, the therapeutic potential of the cannabis plant in the area of cancer treatment has been discovered, and the use of Cannabis by cancer patients has increased significantly[19]. The beneficial effects of Cannabis are related to symptoms of the disease: pain, nausea and vomiting, loss of appetite, weight loss, mood swings, and sleep disorders[19]. Also, Cannabis was found to have immunomodulatory properties. Researches assaying the effects of cannabinoid-based drugs on immunity have shown that various cellular and cytokine mechanisms are suppressed by these agents, mainly by four mechanisms: induction of apoptosis (of T cells, macrophages, splenocytes, and thymocytes), inhibition of cell proliferation, inhibition of production of chemokines and cytokines, and induction of T-regs[19]. Possible clinical use of cannabinoids for the treatment of extremely invasive cancer types is highly supported

by studies proving a decrease of tumor cell invasion by them[19]. Moreover, the lack of severe adverse effects of cannabinoids as compared to the generalized toxicity of conventional chemotherapies. Furthermore, several major side effects of chemotherapeutics, such as emesis and inherent toxicity on noncancerous tissues, have been demonstrated to be even reduced on treatment with cannabinoids[17]. Within cannabinoid-based substances, the Phytocannabinoid CBD has protruded as a particularly interesting drug due to its lack of adverse psychoactive effects, as well as its considerable antitumorigenic properties[17,18,19].

It is postulated that CBD could act on tumor cells, directly or indirectly, through different pathways that may vary in different tumor cells. CBD is an inverse agonist for the CB2 receptor and an antagonist for the CB1 receptor[18, 19]. In addition, CBD has anti-cancer effects acting as an agonist for the transient receptor potential vanilloid (TRPV) 1 and 2, leading to changes in intracellular Ca2+ levels[19]. It is also reported that CBD can induce apoptosis in cancer cells via the production of reactive oxygen species (ROS), caspase activation and activation of p53 dependent apoptotic pathways in cancer cells and down-regulation of mammalian target of rapamycin (mTOR) and cyclin D1[19]. CBD can also upregulate TNF/TNFR1 and TRAIL/ TRAIL-R2 signaling by modulation of both ligand and receptor levels, followed by apoptosis. Furthermore, CBD inhibits human umbilical vein endothelial cells (HUVEC) migration, invasion and sprouting in vitro, and angiogenesis in vivo through down-modulation of several angiogenesis-related molecules. From the immunological point of view, CBD significantly inhibits the recruitment of tumor-associated macrophages (TAM) in primary tumor stroma and secondary lung metastases. CBD promotes the susceptibility of cancer cells to adhere to and subsequently be lysed by Lymphokine Activated Killer (LAK) cells, with both effects being reversed by a neutralizing ICAM-1 antibody[19].

A study used different human lung cancer cell lines, primary tumor cells, and an in vivo intravenous metastasis model, to analyze the contribution of ICAM-1 to the anti-invasive action of CBD. This has been previously described to be mediated via cannabinoid receptor-, TRPV1-, and MAPK-dependent up-regulation of TIMP-1 in human cervical and lung cancer cells. Accumulating evidence highly supported the role of ICAM-1 as a functional link between cannabinoid receptor- and TRPV1-elicited p42/44 MAPK activation and downstream TIMP-1-dependent inhibition of invasion. First, antagonists to CB1 and CB2, as well as an antagonist to TRPV1, were shown to inhibit CBD induced ICAM-1 expression, which is in line withCBD's established cannabinoid- and TRPV1-dependent up-regulation of TIMP-1 expression and subsequent anti-invasive action. Second, CBD induced ICAM-1 expression was found to occur via a receptor-dependent activation of p42/44 MAPK—a pathway likewise shared by the published TIMP-1-dependent anti-invasive action by this cannabinoid. Third, in all cell lines, as well as primary tumor cells from a brain metastasis of a patient with non-small cell lung cancer (NSCLC), CBD elicited a sequential up-regulation of both anti-invasive mediators, ICAM-1 and TIMP-1[19].

Cannabidiol as a potential antiinflammatory treatment in SARS-CoV-2 infection

SARS-CoV-2 is a novel beta coronavirus first reported in China with a 14-day incubation period[20]. In a proportion of individuals, critical illness develops and is characterized by respiratory failure, shock, and multi-organ dysfunction[20]. Mortality ratingalters based on the study population examined, with the death rate among persons requiring mechanical ventilation as high as 88%[20]. SARS-CoV-2 infects types I and II pn eumocytesviaitsreceptorangiotensin-convertingenzyme (ACE)2, which is also them a in receptor for SARS-CoV-2[20]. Under healthy circumstances, bronchoalveolar lavagefluidismadeup of predominantly alveolar macro phages (<80%) and lymphocytes (~10−20%). Alveolar macrophages control the lungs for pathogens, clears senescent cells, share in reparation of -damagedtissue, andenhance T-cellspecificresponses[20]. Importantly, SARS-CoV-2 infection causes hyper-activation of lung macrophages as well as marked infiltration of pro-inflammatory monocyte-derived macrophages (MDMs) into small airways. Acute macrophage stimulation initiates a massive pro-inflammatory response, including IL-6 and IL-1β, which enhance the recruitment of neutrophils and cytotoxic CD8T-cells into the lung's mucosal tissues[21].

Cannabinoids can suppress immune activation and inflammatory cytokine production, suggesting their potential for alleviating excessive inflammation. Endocannabinoid receptors include CB1andCB2. CB1 has higher expression in the central nervous system and a lesser expression on peripheral tissues, including the lungs[22]. CB2 is expressed by lungs as well as varieties

of immune cells, including circulating lymphocytes, monocytes, and tissue mast cells and in lymphoid tissues. Activation of the CB2 receptor can inhibit the release of inflammatory IL-1, IL-6, IL-12, and TNF-α. Constitutive production of endocannabinoids occurs by human lung resident macrophages, which is protective in acute and chronic inflammation, mostly via CB2 receptors[21]. Agonists of CB2 have been shown to inhibit TNF-α from CD14+ monocytes and M1 macrophages and increase expression of antiinflammatory cytokine IL-10. CB2 agonists also induce antiinflammatory FoxP3+ regulatory T-cells (Tregs), which produce TGF-β and IL-10. In addition, CBD has been shown to induce the differentiation of functional immunosuppressive Tregs[22].

In humans, CBD has been tested across a wide dosage range, varying from <1 up to 50 mg pro kg/die depending on the trials and on the explored pathological condition, with both in vitro and in vivo studies suggesting an immunosuppressive action at higher concentrations or doses[22]. CBD should be given orally starting at 100 mg/day titrating up to 300 mg/day (2.5 mg/kg/die) since this dosage did not produce relevant adverse effects even for prolonged administrations (up to 18 weeks) in clinical trials in humans. CBD acts as an in vitro inhibitor of several CYP450 isoforms. Since drug-drug interaction studies between CBD and anti-COVID-19 treatments are lacking; therefore, monitoring of patients for potential drug interactions would be required [22]. It is concluded that SARS-CoV2 causes severe damage through the cytokine storm that causes inflammation by macrophages and other immune cells. Since the CBD has broad antiinflammatory properties, it may represent a potential antiinflammatory therapeutic approach against SARS-CoV2, and it is indeed a therapeutic agent used in clinical medicine and has a favorable safety profile.

Conclusion

Cannabidiol elucidates an impressive plethora of actions, specifically as an anti-inflammatory agent. Many of which could have medicinal significance as well as the lead in the production of pharmaceuticals. CBD is a compound well tolerated in humans with a very low toxicity profile and devoid of psychoactive and cognitive effects. However, more clinical trials are needed to be able to validate its beneficial properties as the possible results that can be discovered by these trials can give a lot of progress from the present preclinical evidence to a practical therapeutic application.

Evaluation the Door-to-Balloon Time in Patient with ST-Elevation Myocardial Infraction (STEMI) in King Abdullah Medical City (KAMC) in Makkah Almukarramah: A Retrospective Single Center Study

Arwa Fairaq[1], Dunia Alfi[2], Halah Bahakeem[2], SehamMalki[3], Raheeq Algarrash[3], Shroug Allehyani[2], Yosra Al-Hindi[1]

[1]Assistant Professor, [2]Pharm. D Graduate, [3]B. Pharm Graduate, Department of Clinical Pharmacy, Faculty of Pharmacy, University of Umm Al-Qura, Makkah, Saudi Arabia

Abstract

Background: ST-Elevation Myocardial Infarctionis a time-sensitive emergency condition. Thus, guidelines recommended 90 minutes or less for door-to-balloon time at a percutaneous coronary intervention-capable hospital and with in 120 minutes or less if transferred from per cutaneous coronary intervention-Uncapable Hospital. The main objective was to evaluate the recommended time needed forreperfusion therapy particularly percutaneous coronary intervention inpatients with ST-Elevation Myocardial Infarctionat King Abdullah Medical City.

Method and Results: A retrospective single center study. Data were obtained from 47 patients records diagnosed with ST-Elevation Myocardial Infarction and treated with percutaneous coronary interventionat King Abdullah Medical Cityfrom Jan 2018 through March 2019. About 36.4% of patients received percutaneous coronary intervention in more than 90 Minutes eventhough they arrived directly at King Abdullah Medical City. For patients who were transferred to King Abdullah Medical City, 63.9% of those patients did not achieve the recommended door-to-balloon time.

Conclusion: High percentage of patients with ST-Elevation Myocardial Infarctionat King Abdullah Medical City did notreceive percutaneous coronary intervention within the recommended timeline.

Keywords: *Ischemic heart disease, ST-Elevation Myocardial Infarction, percutaneous coronary intervention, Door-to balloon time, door-to-needle time.*

Introduction

Ischemic heart disease (IHD) is the number one cause of death worldwide.(1) During the last 15 years, IHD remained one of the leading causes of death. Myocardial Infarction is a type of IHD, and ST-Elevation Myocardial Infarction (STEMI) incorporate about 25% to 40% of Myocardial Infarctioncases, leading to approximately 5% to 6% in hospital mortality.(2-6) STMEI is a life threatening condition that must be diagnosed and treated immediately viacoronary reperfusion.(7) Recent guidelines recommend urgent reperfusion withprimary percutaneous coronary intervention (PCI) or full-dose fibrinolytictherapy for patients with acute STEMI.(8) Among these patients, a significant improvement in the short-term and long-term cardiovascular outcomes such as the mortality and morbidity have been marked due to the quality care guidelines with the emphasis on the time toreperfusion that initiatives by the American

e-mail: amfairaq@uqu.edu.sa

Heart Association and otherorganizations.[9] The early reperfusion can reduce mortality and morbidity inpatient with STEMI.[7] Particularly every 10-min delay in STEMI treatment cause additional 3.3% deaths in PCI patients.[10] Furthermore, primary PCIimprove the outcomes and lowering the recurrent of myocardial infarction and stroke compared with fibrinolytic therapy.[11] Two definitions have been used to measure the time to reperfusion; Door-toballoontime which describes the time from hospital arrival to the time of balloon intervention or using a stent. Likewise, door-to-needle time measures the time from hospital arrival to reperfusion with fibrinolytic administration.[12] The American Heart Association/American College of Cardiology (AHA/ACC)2013 guidelines recommended 90 minutes or less for door-to-balloon time ata PCI-capable hospital for patients with STEMI and within 120 minutes orless if the first arrival was to non-PCI-capable hospital. On the other hand, iffibrinolytic therapy is chosen, the recommended door-to-needle time shouldbe within 30 minutes from hospital arrival.[8]

Previously, some studies investigated the possible reasons of delaying inreperfusion times. Focusing on the arrival time, it has been reported thatpatients arrived during off-hour e.g. weekend, night and holidays had longerdoor-to-balloon time comparedto patients arrived on regular working hours with an increase in mortality.[13,14] Another factor that could delay reperfusion times is gender. Women withSTEMI had longer time to receive reperfusion therapy and higher mortality rates than men.[15] It has been reported that cultural factors can affect the delay in reperfusion therapy in women such as un ability of some women to travel to hospital without male relative.[16,17] Comorbidities factors such as diabetic or hypertension can be associated with delay in door-to-needle time.[18]

In Saudi Arabia, limited studied have been conducted to investigate time toreperfusion in STEMI. Most patients with STEMI had reported to have a delay infibrinolytic therapy.[18, 19]A single center study at King Faisal Cardiac Center (KFCC) reported door-to-balloon time of < 90 minutes in 62%only. So, door-to-balloon time still behind the recommended time.[20] In addition, a standardized Code-STEMI programin King Khalid University Hospital's (KKUH) have been established and code-STEMI implementation significantly improved door-to-balloontime.[21]

To the best of our knowledge, no data available on the assessment of reperfusion time in the emergency centers in Makkah. Early reperfusion in STEMI cases is critical. Therefore, we aimed in this study to evaluate time needed for reperfusion therapy particularly percutaneous coronary intervention (PCI) in patients with STEMI and assess different factors that may delay reperfusion at King Abdullah Medical City(KAMC).

Methodology

Study design and setting: We conducted a retrospective study. Data for 47 patients were obtained from Jan 2018 through March 2019 based on patient medication records obtained from an electronic medical record (EMRs) from KAMC in Makkah, Saudi Arabia.

Data collection and assessment: Data were collected from the electronic medical records in KAMC in Makka. A data collection form was filled with patient demographics (patient name, age, diagnosis and drug therapy for the respective diagnosis), Arrival time (off hours versus regular hours. Regular hours is definedas 08 am to 17 pm during the weekdays, and off hours is defined as weekends, holidays or time between 17 pm and 08 am during the weekdays) and reperfusion time. Then time from arrival until reperfusion was calculated and patient demographics and reasons for delays in reperfusion therapy were analyzed.

Inclusion and exclusion criteria: Patients who were above 18 years old and presented to KAMC and diagnosed with ST-segment elevation myocardial infarction (STEMI) and had PIC between Jan 20108 and March 2019 were enrolled. While exclusion criteria included: receiving thrombolytic therapy before arrival or thrombolytic therapy for conditions other than myocardial infarction, starting myocardial infarction attacks at hospital, unknow arrival time or unknow reperfusion time.

Outcomes and measurement: Our primary outcome was to evaluate the door-to-balloon time for patients with ST-segmentelevation myocardial infarction (STEMI) undergoing primary percutaneouscoronary intervention (PCI) in King Abdulla Medical Center (KAMC) under different circumstances such as arrival time, ECG receiving time and direct/indirect presentation.

Statistical analysis: All the variables were analyzed using SPSS Var 23.0 software 2015. Descriptive statistics were calculated and presented as means and standard deviations. For continuous variables such as door to

balloon time in minutes, median was calculated. While other variables reported in percentages such as gender, hypertension, diabetes mellitus, dyslipidemia, previous myocardial infarction, renal failure and smoking.

Results

Demographic Characteristic: Patients included in this study were predominantly male (87.2%, no=41). The mean age was 57 (SD ± 14.2). Majority live in Makkah (87.2%, no=41). History of hypertension and diabetes was present in 42.6% (no=20). Demographic characteristic of patients who were involved in this study are summarized in table 1.

Assessment of Door-to-balloon time: After reviewing patients' profiles, data represent around 63.6% of patients (n=7) who were arrived directly at KAMC received PCI within 90 minutes(Door-to-balloon time). The median door to balloon time was 42 minutes (IQR: 29– 67 minutes) for those patients. However, 36.4% of patients (n=4) received PCI in more than 90 Minutes (Figure. 1).

For patients transfer to KAMC from another hospital, data report 63.9% (n=23) of patients received PCI (door-to-balloon therapy) within more than 120 minutes and only 36.1% (n=13)met the guidelines recommended time for the PCI; within 120 Minutes (Figure. 1)with median door to balloon time of 61 minutes (IQR: 27 – 74 minutes).

Assessment of Door-to-balloon time according to arrival time: All patients included in this study who arrived directly to KAMC arrived on regular hours. Around 64% of those patients received PCI within 90 minutes while 36% of these patients received PCIin more than 90 Minutes(Figure. 2).

For patients who were transferred from non-PCI-capable hospital about 60% of patients received PCI in more than 120 minutes even though they arrived within regular hours compared to 40% received PCI within 120 minutes. While around 80% of patients who were transferred from non-PCI-capable hospital and arrived during off hours time, had delayed inreceiving PCI in more than 120 minutes (Figure. 3).

Assessment of door-to-balloon time according to ECG: Majority of patients(83%) who received ECG within 10 minutes received PCI within 90 minutes. However, from patients who received ECG after 10 minutes, 60% had a delay in receiving PCI in more than 90 minutes (Figure. 4).

For patients who were transferred from non-PCI-capable hospital, 43% received PCI in more than 120 minutes even though they received ECG within10 Minutes. Importantly, 77% of patients who were transferred from non-PCI-capable hospital received ECG after 10 minutes with a delay in receiving PCI in more 120 minutes (Figure. 5).

Table 1: Demographic characteristic. Table represents demographic characteristics of the study population; data presented in actual patient's numbers and percentage (%).

Demographic characteristic		Actual patients' numbers (Percentage %)
Age (Years)	30-49	15(32.9%)
	50-69	23(48.9%)
	70-89	8(17.0%)
	>90	1(2.1%)
Gender	Male	41(87.2%)
	Female	6(12.8%)
Area of residence	Makkah	41(87.2%)
	Outside Makkah	6(12.8%)
Nationality	Saudi	21(44.7%)
	Others	26(55.3%)

Demographic characteristic		**Actual patients' numbers (Percentage %)**
Medical history	Hypertension	4 (8.5%)
	Diabetes	4 (8.5%)
	Dyslipidemia and smoking	2 (4.3%)
	Diabetes and smoking	2 (4.3%)
	Hypertension and diabetes	20 (42.6%)

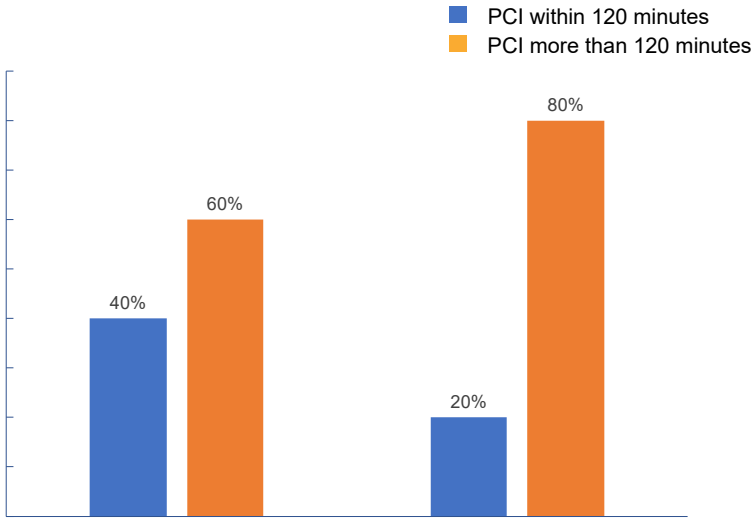

Figure 3. Door-to-balloon time for patients transferred from non-PCI capable hospital based on arrival time either regular hours or off hours (x-axis across the page) and patient percentage % (y-axis going into the page).

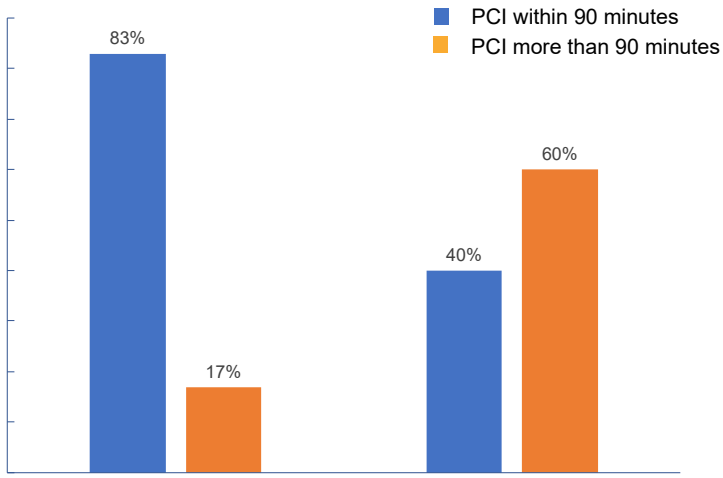

Figure 4. Door-to-balloon time for patients directly arrived at KAMC according to time needed to have ECG either within 10 minutes of arrival or more than 10 minutes of arrival (x-axis across the page) and patient percentage % (y-axis going into the page).

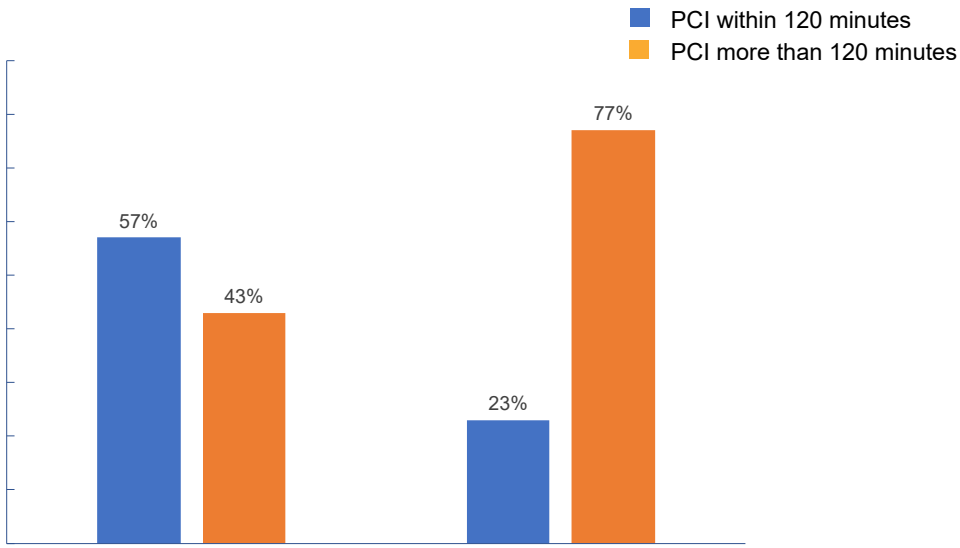

Figure 5. Door-to-balloon time for patients transferred from non-PCI capable hospital according to time needed to have ECG either within 10 minutes of arrival or more than 10 minutes of arrival (x-axis across the page) and patient percentage % (y-axis going into the page).

Discussion

According to recent guidelines, patients with STEMIshould have time-to-needle within 90 minutes if arrived directly to PCIcapable hospital or within 120 minutes if transferred from non PCI capablehospital.[8] However, our study shows high percentage of patients with STEMIhad a delay in receiving PCI. Unfortunately, 36.3% of patients with STEMI received PCI in more than 90 Minutes even though they arrived directly toKAMC. Receiving. For patients transferred from non-PCI capable Hospital such as: Al-Noor Specialist Hospital, Heraa General Hospital, East Jeddah General Hospital, King Faisal Hospital in Makkah or King Faisal Hospital in Taif, higher percentage around 63.8% of patients did not meet the guidelines recommended time forthe PCI which is within 120 Minutes.

The delay in the PCI may be due to arriving at off working hours such as weekends, holidays or after 5:00 pm. Our data shows around 20% increase in patients percentage who have a delay in PCI when they arrived off hours. Another factor that may affect the delay in PCI, the delay in the ECG per forming as the recommended time for having ECG is within 10 minutes of hospital arrival.[8]

Small Number of patients is the main limitation of this study. In addition, the effect of delaying time-to-needle in patients with STEMI patients on mortality remains unclear.

At last, hospitals should consider better strategies to ensure that patients with STEMI able to have reperfusion therapy within the recommended timeline. Easer system that accelerate patients access and simplify procedures for their entry as well as transferring between hospitals and universal healthcare system are needed to be implemented in Saudi Arabia in order to meet the international standards and guidelines.

Conclusion

High percentage of patients with STEMI at KAMC did not receive PCI within the guidelines recommended time-line. More strategies have to be applied to ensure recommended door-to balloon time achievement.

The Adsorption Effect of Pine Resin (*Pinus Merkusii*) in Reducing Hardness ($CaCO_3$) in Clean Water

Ashari Rasjid[1], Syamsuddin S.[2]

[1]Associate Professor, [2]Assisstant Professor, Department of Environmental Health, Researcher in the Center of Excellent of Urban Health, in Health Polytechnic of Ministry of Health in Makassar, Indonesia

Abstract

Globally, the quantity of land and water resources on earth is relatively fixed, while the quality progressively decreased. One of the problems with clean water quality is the hardness level caused by valence cation ions of two metals such as Ca2 +, Mg2 +, Fe2 + and Mn2 +. The purpose of this study is to determine the effect of pine resin (*Pinus merkusii*) in reducing hardness (CaCO3) in clean water. This type of research is a quasi-experimental study by testing the treatment of hard water using pine resin media (*Pinus merkusii*) measuring ± 5 cm with variations in the thickness of the media that is 20 cm, 40 cm, and 60 cm by replicating 3 times. The results of this study found that the reduction in hardness at 20 cm media thickness by 42.14%, at 40 cm thickness by 51.58%, and a thickness of 60 cm 73.78%. And the one way ANOVA test results showed the value of the comparison between hardness after filtration was sig.0.00 ≤ 0.05 so that there was a significant difference between the thickness of the pine resin (*Pinus merkusii*) 20 cm, 40 cm, 60 cm. The conclusion from the study of water management through filtration using pine resin media (*Pinus merkusii*) meets the requirements according to the Health Ministry of Indonesia Regulation Number 32 of 2017. Water treatment with pine resin if used for the community should use a thickness of 60 cm. As for researchers, it can further use other variations such as the thickness of the pine resin used.

Keywords: *Adsorption, Pine Resin, Hardness, and Clean Water.*

Introduction

Water is the essence of life. With the presence of water, all living things on this earth can grow and develop properly. Water covers 75% of the earth's surface. The presence of water on this earth covers 97% in the ocean, 2% in ice sheets or glaciers, 0.6% in the soil, 0.3 is water vapor, 0.1 is in the soil surface. In living cells, 70% or more consists of water, including the human body. In the bones, there is water as much as 22% of the bone weight and 83% in the blood and kidneys.

The importance of water for health can be seen from the percent of the amount of water in the body's organs, which is 80% in the blood, 25% in the bones, 75% in the nerves, 80% in the kidneys, 70% in the liver, and 75% in the muscles.[1]

Reducing 4% to 5% of the water in our body will be able to affect the decline in workability by 20% to 30% and greater water loss can be fatal for us.[2]

In addition to quantity, decreasing water quality is also very influential in human health, one of which is high hardness in some areas, especially in South Sulawesi.

Some areas surveyed by researchers regarding hardness levels in several areas in South Sulawesi showed that the level of hardness in clean water taken from community dug wells was 626 mg/L.[3] A survey in 2015 in Tonasa 1, Pangkep Subdistrict, the level of hardness obtained was 380.9 mg/L.[4] Another survey by in 2016 in Citta Subdistrict, Soppeng District, the level of hardness obtained was 323.83 mg/L.[5]

The hardness standard is 500 mg/L,[6] while other references stated that the hardness level> 300 mg/L is classified in very hard water.[7] To overcome this problem, it needs treatment efforts before the water is used so it will not interfere with health such as blockage of heart arteries and kidney stones or damage household cookware and household or industrial piping networks.

Hardness can be reduced by several ways such as heating to temporary hardness, adding chemicals to reduce pH in raw water such as the addition of lime soda (Na2CO3) or the addition of caustic soda (NaOH), the recarbonation process for pH stabilization, ion exchange using zeolites, or the use of resins both natural and synthetic resins.[8]

Resin is a hydrocarbon compound that can exchange ions so that the ions are often in drinking water treatment or wastewater treatment.[9] Natural resins can be obtained from plant sap such as pine trees (*Pine merkusii*) which are processed through the distillation process. This pine sap contains abietic acid (C20H30O2) and terpene acid (C5H8).[10] The use of this media only requires a relatively low cost, and is widely available in South Sulawesi and can be used many times.

Based on the description above, the authors are interested in examining how much the ability of pine resin adsorption in reducing hardness levels in clean water.

Materials and Method

This type of research is a quasi-experimental study by testing the treatment of hard water using pine resin media (*Pinus merkusii*) measuring ± 5 cm with a variation of media thickness of 20 cm, 40 cm, and 60 cm by replicating 3 times.

In this study, the sample used was clean water from residents' dug wells in the Citta Subdistrict, Soppeng Regency which had a high level of hardness. This research was conducted at the Makassar Health Polytechnic College precisely at the College Workshop on Environmental Health and laboratory analysis testing was conducted at the Chemical Laboratory majoring in environmental health Makassar Health Polytechnic.

The time of this study was divided into two stages, namely the preparatory stage, which includes the collection of secondary data that took place from February to March 2019, and the implementation phase, including research activities that took place from May to August 2019.

The sample in the study was clean water from a community dug well in Citta Subdistrict, Soppeng Regency which had a high level of hardness. Primary data using data obtained based on the results of processing with pine resin (*Pine merkusii*) in reducing hardness in clean water. Secondary data was data obtained from various references both articles, books, and other literature that were considered to be able to support existing theories, and were considered to have a relationship with this research.

The data analysis technique was carried out with the ANOVA test from observations obtained at the time of the implementation of the experiment and described in tabular form. The results of the study were accompanied by descriptions based on supporting theories.

Results

Large Decreased Hardness in Thickness of Pine Resin Media (Pinus merkusii) 20 cm. Based on research activities and examination of clean water samples in the laboratory, the average results can be described in Table 1:

Table 1: Average Hardness After Through Pine Resin Media Filtration Thickness of 20 cm in the 2019 Dug Well Water Sample

Before Treatment	Repetition	Hardness Level (mg/l)		Effectiveness of Decrease (%)
		After Treatment		
		Control	The thickness of 20 cm	
660.96	1	579,36	380.26	42.47
	2	628.32	391.68	40.74
	3	595.68	375.36	43.21
Average		601.12	382.43	42,14

Based on Table 1. above was the average yield of hardness before and after treatment with pine resin media thickness of 20 cm used in water samples from the first repetition to the third repetition. The results for hardness before treatment were 660.96 mg/l with three times repetition to control the average yield of 601.12 mg/l, after treatment on pine resin media thickness of 20 cm obtained an average result of 382.43 mg/l with the effectiveness of 42.14%.

Large Decreased Hardness in Thickness of Pine Resin Media (*Pinus merkusii*) 40cm. Based on research activities and examination of clean water samples in the laboratory, the average results can be described in Table 2:

Table 2: Average Hardness After Filtration Through Pine Resin Media Thickness of 40 cm in 2019 Dug Well Water Samples

Before Treatment	Repetition	Hardness Level (mg/l)		Effectiveness of Decrease (%)
		After Treatment		
		Control	The thickness of 40 cm	
660.96	1	652.80	328.03	50.37
	2	612.00	313.75	52.53
	3	542.64	318.24	51.85
Average		602.48	320.01	51.58

Based on Table 2 above was the average yield of hardness before and after treatment with pine resin media thickness of 40 cm used in water samples from the first repetition to the third repetition. The results for hardness before treatment were 660.96 mg/L with three times repetition to control the average yield of 602.48 mg/L, after treatment on pine resin media thickness of 40 cm obtained an average result of 320.01 mg/l with the effectiveness of 51.58%.

Large Decreased Hardness in Thickness of Pine Resin media (Pinus merkusii) 60cm. Based on research activities and examination of clean water samples in the laboratory, the average results can be described in Table 3:

Table 3: Average Hardness After Filtration of Pine Resin Media Thickness of 60 cm in 2019 Dug Well Water Samples

Before Treatment	Repetition	Hardness Level (mg/l)		Effectiveness of Decrease (%)
		After Treatment		
		Control	The thickness of 60 cm	
660.96	1	652.80	181.97	72.46
	2	530.40	178.70	72.96
	3	593.64	159.12	75.93
Average		592.28	173.26	73.78

Based on Table 3 above was the average yield of hardness before and after treatment with pine resin media thickness of 60 cm used in water samples from the first repetition to the third repetition. The results for hardness before treatment were 660.96 mg/L with three times repetition to control the average yield of 592.28 mg/L, after treatment on pine resin media thickness of 60 cm obtained an average result of 173.26 mg/L with the effectiveness of 73.78%.

The following are the results of data analysis using one way ANOVA statistical tests to determine whether there are differences in filter media used as interventions/treatments:

Table 4: Statistical Analysis Results Using One Way Anova Test Difference in Decreased Hardness Levels After Filtration Using Pine Resin Media with Thicknesses of 20 cm, 40 cm, and 60 cm in 2019

	Sum of Squares	df	Mean Square	F	Sig.
Between Groups	492731,292	5	98546.258	76,328	0.00
Within Groups	15493,054	12	1291,088		
Total	**508224,346**	**17**			

One way ANOVA test results based on Table 4 showed the comparison value between hardness levels after going through filtration where filtration results at thicknesses of 20 cm, 40 cm, and 60 cm were obtained from the One Way ANOVA statistical test results using SPSS results of Sig. if ≤ 0.05 then it showed that there was a difference but if the Sig. ≥ 0.05, it is showed that there was no difference.

The results above indicated a difference because of the Sig. 0.00. Or 0.00 ≤ 0.05 so the hypothesis was accepted this showed that for the decrease in hardness there was a significant difference between the thickness of the pine resin media 20 cm, 40 cm, and 60 cm.

Discussion

Water is one of the natural resources that have a very important function for human life and life, as well as to advance public welfare so that it is the basic capital and the main factor of development. Water is also an environmental component that is important for the survival of humans and other living things. That can be seen from the fact that 70 percent of the earth's surface is covered with water and two-thirds of the human body consists of water.[11]

Groundwater is a part of the water in nature that is below the surface of the land. The formation of groundwater follows the cycle of water circulation on earth called the hydrological cycle, which is a natural process that takes place in water in nature that undergoes a sequential and continuous displacement.[12]

The hardness standard in Indonesia Regulation is 500 mg/L[6] but another literature[7] stated that the hardness level>300 mg/L is classified in very hard water. To overcome this problem, it needs treatment efforts before the water is used so it will not interfere with health such asblockage of heart arteries and kidney stones or damage household cookware and household or industrial piping networks.

Hardness can be reduced by several ways such as heating to temporary hardness, adding chemicals to reduce pH in raw water such as the addition of lime soda (Na2CO3) or the addition of caustic soda (NaOH), the recarbonation process for pH stabilization, ion exchange using zeolites, or the use of resins both natural and synthetic resins.[8]

Hardness is classified in two ways, namely based on metal ions and based on anions associated with metal ions. Based on metal ions, hardness is divided into calcium hardness and magnesium hardness. Based on anions associated with metal ions, hardness is divided into carbonate hardness and non-carbonate hardness.[5]

Hardness is caused by excessive amounts of mineral-containing metal cations with two-dimensional cations. Usually what often causes hardness is the Ca ++ and Mg ++ cations. Total hardness is hardness caused by Ca ++ and Mg ++ together.[5]

Resin is a hydrocarbon compound that can exchange ions so that the ions are often in drinking water treatment or wastewater treatment.[9] Natural resins can be obtained from plant sap such as pine trees (*Pine merkusii*) which are processed through the distillation process. This pine sap contains abietic acid (C20H30O2) and terpene acid (C5H8).[10] The use of this media only requires a relatively low cost, and is widely available in South Sulawesi and can be used many times.

The hardness of water is different from the acidity of water, even though the two are closely related. Both can be easily distinguished. Acidic water usually shows a soft reaction. Therefore, the hardness of water is often

called the hardness of the water.[13] Hardness is the nature of water caused by the presence of valence metal ions. Such ions can react with soap to form lumps. The main cause of hardness is cation Ca2+, Mg2 +, Fe2 + and Mn2 +.[14]

Hardness in groundwater is caused by contact between groundwater and the layers of rocks. Rainwater that falls to earth cannot dissolve the large amounts of solid material contained in water. That ability can only be achieved if it has reached the soil where CO2 is released by the reaction of bacteria, this CO2 in the soil is in equilibrium with carbonic acid.

Water that contains high hardness will result in high use of soap, due to the chemical relationship between hardness ions and soap molecules, causing detergent properties of soap to disappear. Excess Ca2 + ions and CO3 ions (one of the alkalinity ions) result in the formation of scale on the pipe and pan walls caused by the deposition of calcium carbonate CaCO3.

The processing used in this research was processing with filtration which has a basis as physical, chemical, and biological filtering to separate/filter out particles that were not deposited in the sedimentation process through porous media. The filtering process was needed to separate the small/fine-sized flocks that cannot be deposited by the deposition process.[11]

One effort to overcome hardness is by softening hard water. Softening is the removal of certain ions that are in water and can react with other substances until the water distribution and use are disrupted. Theoretically, the reduction or softening of water hardness consists of various processes that exist in the process of softening hard water, namely using an ion-exchange system where water treatment uses resin or zeolite to replace unwanted ions in water such as Ca2 + and Mg2 + and replace them with N + ions and K +.[15]

This process is very fast (20-30 minutes), cannot take place with other reactions and raw water must not be turbid, installation and operation are complicated, high efficiency, price is relatively expensive (suitable for the industry). This process can be used for processing permanent and temporary hardness by separating unwanted ions contained in hard water. The material used in this process is in the form of activated carbon and or synthetic resin which is put into a column where water can already flow through the compounds.[16]

Adsorption is the capture or binding of free ions in water by adsorbents. Examples of substances used for the adsorption process are zeolites and resins which are the polymerization of polyhydric phenols with formaldehyde. For example, the binding of Ca2 + and Na2 + ions. Each gram of resin can adsorb 4-9 MeV (milliequivalent). The amount of adsorbent needed depends on the concentration of the solution. The higher the concentration of the solution, the greater the adsorbent needed to purify water.[9]

Pine resin has been through the distillation process produced by the merkusii pine tree classified as oleoresin which is a liquid resinous acid in turpentine that trickles out when the resin channel on wood or needle bark is cut or broken. The name oleoresin is used to differentiate pine resin from natural resin that appears on the skin or is contained in cavities in wood tissue as a genus of members of the *Dipterocarpaceae*, *Leguminoceae*, and *Caesalpiniaceae* families.[10]

The sap that comes from the pine tree is dark yellow and sticky, which consists of a complex mixture of chemicals. The most important elements that makeup pine resin are terpene acids and abietic acids. The mixture is dissolved in alcohol, gasoline, ether, and some other organic solvents, but it is not soluble in water. Besides, from the results of the distillation of *Pinus merkusii* sap produced an average of 64% gondorukem, 22.5% turpentine, and 12.5% impurities. The resin canal is not a part of the wood, but a cavity surrounded by parenchymal cells or epithelial cells. All layers surrounding the resin channel are called epitellium.[10]

Distilled pine sap will produce gondorukem (gum rosin) and turpentine (gum turpentine). The color is pale, clear, and sticky and when evaporated becomes brittle, it states that pine resin is composed of 66% resinous acid (resin), 25% turpentine (monoterpene), 7% neutral non-volatile material, and 2% water.[17]

Gondorukem or resinis a hydrocarbon compound that can exchange ions so that it is often used in drinking water treatment or wastewater treatment. At present, there are two types of resins, natural resins, and synthetic resins. Natural resins are processed from pine wood sap taken specifically, usually in the industry used for lacquer. Synthetic resins are made from hydrocarbons through chemical processes. This synthesis resin is widely used in the plastics industry, household appliances, toys, and decoration.[9]

The use of resin is one method to treat water by passing water to the resin media. Water treatment with this resin is one method of separation according to chemical changes by exchanging ions. The principle of water treatment with resins is to replace or exchange ions bound to the polymer filling resin with the ions that are passed. There are two kinds of ion exchange resins.

Cation exchange resin is a resin that will exchange or take cations from the solution. For example, if the water contains Fe (iron) ions the Fe ions will be bound by resin into R-Fe ions. However, the bond is not permanent so when it is saturated, the resin used for water filters can be washed with warm water that is given salt (NaCl). Furthermore, the resin will be pure again and can be reused. The resin takes the role of taking cations from the solution. Cation exchange resins take cations from the solution. Cation exchange resins contain carboxylic, sulfonic, phenolate or other groups and several equivalent cations.[9]

Anion exchange resins are used using separation based on the charge held by the solute. One example is the ion group containing sodium.[9] Ion exchange that occurs in the filtration process is also influenced by the thickness and height of the water sample when jetting thicker the pine resin media used, the higher the decrease in hardness levels in water through the filtration process with pine resin media.

The basic principle of filtration is physical, chemical, and biological particle filtering to separate/filter out particles that are not deposited in the sedimentation process through porous media.[18] The most influential filtration principle in this research is the deposition process that occurs on slow filters or filters with flow direction from the bottom up. The space between the grains of sand media functions as small sedimentation. Even small particles, as well as colloids and some bacteria, will settle in the space between the grains and adhere to the physical effect (adsorption) grains.

Filtration in a clean water treatment system is the process of removing fine particles/flocks that pass through the sedimentation unit, where the particles/ flocks will be retained on the filtering media as long as the water passes through the media. The design of the research that has been made by using a filtering device from PVC pipe that is designed so that it becomes a simple filtering device using media, the filtration process used is in the direction of up-flow which is a water treatment system by passing through a media filter with direction flow from the bottom up so that if the media used is dirty the washing process will be very easy.

Upstream flow direction requires a lot of water samples because water samples will be flowed gravity and also use pressure so that water samples will flow through the media that has been prepared.

When viewed from the effectiveness of the thickness of the filter media, filtration with a thickness of pine resin 60 cm is the most effective in reducing hardness in water samples, from 660.96 mg/L down to an average of 173.26 mg/L with the effectiveness of 73.78% compared to the thickness of pine resin 20 cm which dropped to an average of 382.43 mg/L with the effectiveness of 42.14%, and the thickness of a 40 cm pine resin dropped to an average of 320.01 mg/L with the effectiveness of 51.58%.

Based on the results of statistical tests using one way ANOVA test to determine the differences in more than two interventions with replication. On the results of hardness inspection using variations in the thickness of the pine resin media 20 cm, 40 cm, and 60 cm, the Sig. the value was obtained. 0.00<0.05 so that the hypothesis was accepted, this showed that for hardness there was a significant difference in the intervention by using variations in the thickness of the pine resin media 20 cm, 40 cm, and 60 cm.

However, if compared with Health Ministry of Health Regulation Number 32 in 2017 concerning Environmental Health Standard Quality and Water Health Requirements for Sanitary Hygiene, Swimming Pools, Solus Per Aqua and Public Baths, especially on water health requirements for sanitary hygiene requirements from total samples for hardness levels (CaCO3) nothing has passed the established quality standard of 500 mg/L, on the results of sample water that has been through filtration treatment.

Conclusion

Based on the results of research that has been done can be concluded that there was a decrease in hardness of an average of 42.14% and qualify for water through filtration treatment with the media at a thickness of pine resin (*Pinus merkusii*) 20 cm. The average hardness reduction of 51.58% and qualify for water through filtration treatment with media at a thickness of pine resin (*Pinus merkusii*) media of 40 cm. This research

found a significant decrease in hardness of an average of 73.78%, the most effective and eligible for water through filtration treatment with media at a thickness of pine resin (*Pinus merkusii*) 60 cm. The significant value between the difference in thickness of the pine resin media 20 cm, 40 cm, 60 cm is sig. 0.00<0.05.

Based on the conclusions above, the authors suggest for the Community that people who want to use this processing, preferably using a thickness of 60 cm or more so that the results of more optimal processing. Besides, if the processing is used continuously for household needs, then the filter media should be cleaned for a certain period. Other researchers can then try to do filtration by comparing variations by adding different thicknesses.

Assessment of the Knowledge and Attitude of Eligible Couples towards Tubectomy and Vasectomy

Ashish Dass[1], Jaspreet Kaur Dullat[2], Maninder Singh[3], Aanchal[4], Balpreet Kaur[4], Chandresh[4], Jahangir[4]

[1]Nursing Tutor, [2]Associate Professor, [3]Assistant Professor, Chitkara School of Health Sciences, Chitkara University, Punjab, India, [4]B.Sc. Nursing 4th Year Students

Abstract

Background: The populace is quickly expanding and has become a significant issue with the populace developing at a yearly pace of 1.2%. India will have more than 1.53 billion people before the completion of 2030 with the masses improvement rate at 1.58%.

Materials and Method: A Non-Experimental Descriptive Survey Research Design was used. A sample was comprised of 50 males and 50 females belongs to peer group of 20-45 years. Purposive sampling technique was utilized to gather sample for additional investigation. The data was aggregated by applying selected variables, Structured Knowledge Questionnaire and Attitude Rating Scale.

Results: The result showed a significant association of knowledge of males with their selected variables. The calculated p value of males and females with selected variables of knowledge and attitude was nonsignificant which showed that there was no association between the level of knowledge and attitude of males and females towards tubectomy and vasectomy.

Conclusion: It was concluded that Knowledge of the males and females regarding tubectomy and vasectomy was in average and Attitude was moderately favourable. There was not any relationship between knowledge and attitude of males and females regarding tubectomy and vasectomy.

Keywords: *Knowledge, attitude, males, females.*

Introduction

India is a second largest country because of its population that is 1,311,559,168(1.31 billion), on the other hand China is the top largest country because of its population 1,380,914,176(1.38 billion). These figures show that India came to for all intents and purposes 17.74 of the all out populace, which shows that every person out of six social orders is has a spot with India. Be that as it may, the crown of the world's most prominent nation is China's obligation from a long time. India is additionally expected to take a similar circumstance by 2030. With the people advancement rate by 1.58%, India is typical for over than 1.53 billion people before the completion of 2030[1] **(Taneja, 2014).**

According to the world health organization, 1 million conceptions takes place every day and about 50% of these contraceptions are unplanned and 25% of them are unwanted (ladipo, 1999). Everyday about 150,000 unwanted pregnancies are terminated. **(Etuk, 2003).**

In India, The national Family Planning Programme was started in 1952 to making it the first country in the world to do so. In spite of this about 56% eligible couples in India are still unprotected against contraception[3]. **(Reddy, 2003).**

Corresponding Author:

The contraception alludes to the avoidance of the origination by the utilization of different sexual practices, surgeries, synthetic compounds and medications. The main purpose of seeking contraception is to prevent the women from becoming unwanted pregnancy. That's why it is considered as a contraceptive. Its main aim is to attain privacy and comfort in the physical or sexual relationship. In the society, the couples are allowed to enjoy and fulfill their sexual desires without fear of unwanted pregnancies[4]. **(Jain R, 2011).**

So couples now a days confronting clashes with objectives of accomplishing fulfilling sexual coexistence and keeping their little family. In the event that individuals neglects to keeping their family little outcomes in undesirable pregnancies and unsafe premature births. On the off chance that the premature birth looking for is late or in unhygienic conditions or in the hands of hazardous suppliers, it can prompt conceptive horribleness just as maternal mortality. **(Jain r, 2011)**.

Methodology

This study was done in the month of February, 2019 in the Panjab state of India. A sample of 100 (50 Males and 50 Females) participated in this study with the prior permission from the sarpanches of Respective Villages. A Non Experimental Descriptive survey research design in whichMales and females aged 20-45 years having one or more children with alertness, oriented and comprehend to respond, speak and understand Hindi, willing to participate and residing in selected rural villages of Rajpura, Punjab were included. Males and Females who were not accessible at the hour of information assortment were prohibited. A Non-Probability Purposive Sampling Technique was owned for data collection from the participants through the medium of Structured Knowledge Questionnaire and Attitude Scale.

Description of Tool:

1. **Selected variables:** The selected variables include Gender, Age, Religion, Type of family, Educational status, Occupation, socio economic class, Number of children, Age at marriage, Married life, Have you ever heard about tubectomy and vasectomy, Source of information about tubectomy and vasectomy.
2. **Structured Knowledge Questionnaire:** This questionnaire was adopted to assess the level of knowledge of males and females toward stubectomy and vasectomy. It contains 20 multiple choice items regarding tubectomy and vasectomy covering the content area of:

- Concept and types
- Procedural knowledge
- Assessment
- Post care

Each correct answer was graded with one point score and every incorrect answer was graded as no point. Consequently least score was 00 and greatest score was 20. The calculated Cronbach's Alpha Internal consistency was 0.78 (Adequate range is 0.7-0.9).

3. **Structured Attitude Rating Scale:** This scale was used to measure the attitude of participants with regard to tubectomy and vasectomy. It consist of total 28 items used to measure the attitude of participants in terms of Strongly Agree, Agree, Uncertain, Disagree and Strongly Disagree and were graded from 1-5.

Out of 28 items,11 items were positive statements scored as 5,4,3,2,1 while 17 items were negative scored as 1,2,3,4,5.

Procedure: In the wake of getting the formal regulatory endorsement, the last investigation was led in the period of April 2018 at chose villages of Rajpura, Punjab. Participants were selected by purposive sampling and information was gathered by utilizing tools of the study. A prior consent was taken from the participants. Earlier data was given to the subjects about the motivation behind the investigation.

Data Analysis:

- **Descriptive statistics:** Frequency distribution was issued to show the selected variables.

Correlation Coefficient test was utilized to find out the relationship between knowledge and attitude number score of Males & females towards tubectomy and vasectomy.

Chi square Test was used to find out the Association of knowledge and attitude score of males and Females towards tubectomy and vasectomy with their selected variables.

Results

Frequency distribution in terms of level of knowledge score and Attitude scores of participants in

figure 1 and Figure 2 illustrates that further more half of the males 27(54%) had an moderate level of knowledge while 22(44%) of the males had low level of knowledge and only 1(2%) of male had high level of knowledge. Out of the 50 females, Majority of them 30(60%) had average level of knowledge while 20(40%) had low level of knowledge as shown in figure 1.

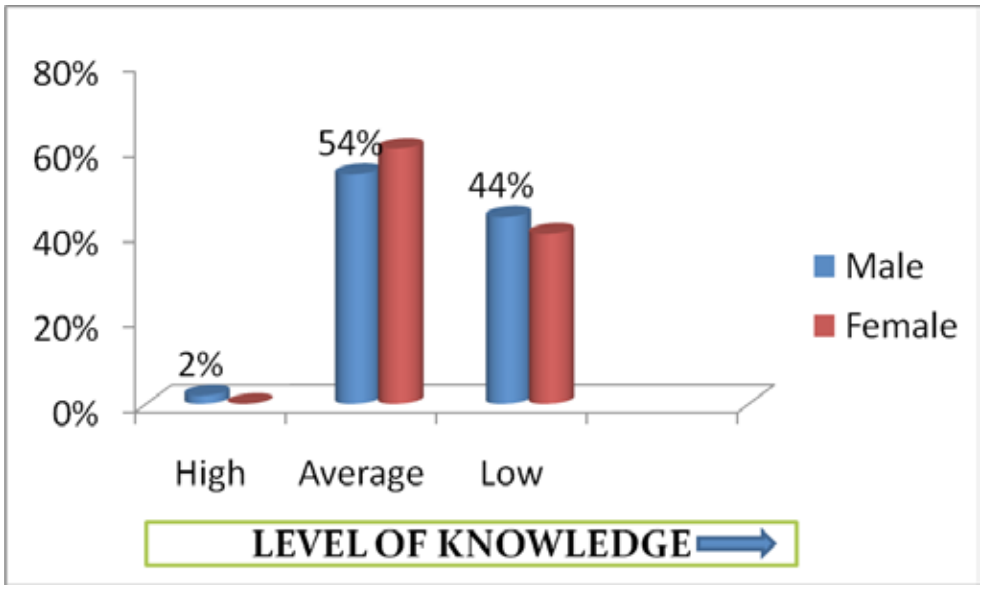

Figure 1: Percentage distribution in terms of level of knowledge among eligible couples towards tubectomy and vasectomy.

Frequency and percentage distribution in terms of level of attitude of eligible couples towards tubectomy and vasectomy. Out of 50 males, Half of the males 25(50%) had moderately favourable attitude and 24(48%) of the males had favourable attitude while only 1(2%) of the males had unfavourable attitude towards tubectomy and vasectomy. Out of 50 females, majority of the females 35(70%) had moderately favourable attitude while only 15(30%) of the females had favourable attitude towards tubectomy and vasectomy as shown in figure 2.

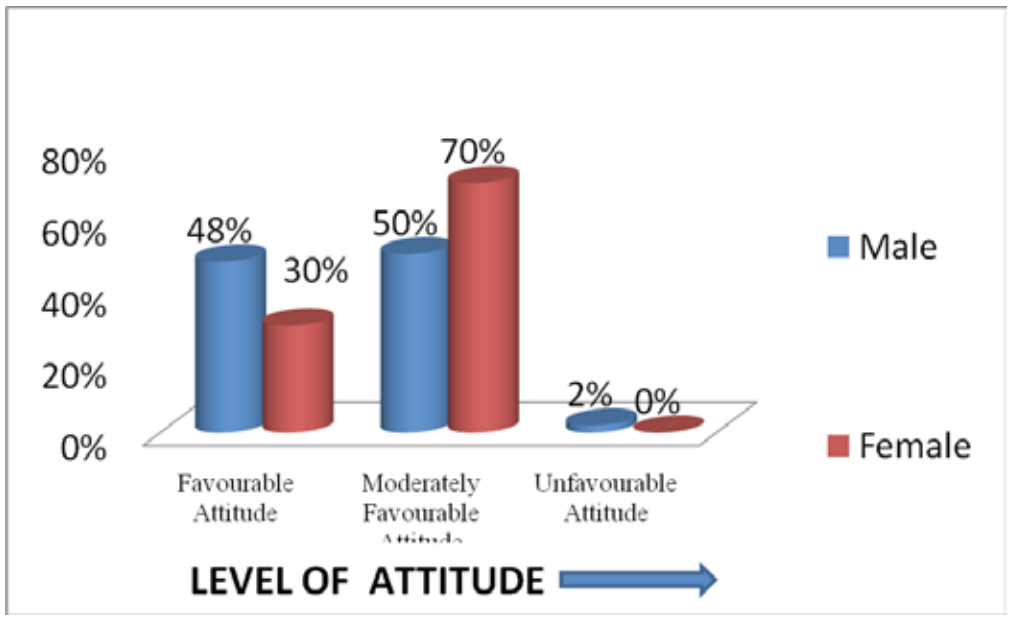

Figure 2: Percentage distribution in terms of level of attitude among males and females towards tubectomy and vasectomy.

Relationship between the knowledge and attitude scores of participants towards tubectomy and vasectomy in table 5 which shows that r value of males and females were 0.10 and 0.66 respectively which were non significant at 0.05 level of significance calculated by Co-relational Co-efficient. So there was no relationship between knowledge and attitude of participants towards tubectomy and vasectomy as shown in table 2.

Table 1: Correlation between the knowledge and attitude of males and females towards tubectomy and vasectomy. N = 100

Group		Knowledge score r(P value)	Attitude score R(P value)
Knowledge	Males	---	0.10(0.23)
	Females	---	0.66(0.06)

Chi square showing association between level of knowledge and attitude of males and females towards tubectomy and vasectomy. The findings reveals that computed p value of males and females with selected variables of knowledge and attitude found to be not significant at 0.05 level of significance. This shows there is no association between the level of knowledge and attitude of males and females towards tubectomy and vasectomy as shown in table 3.

Table 2: Chi square showing association in terms of level of knowledge and attitude of males and females towards tubectomy and vadectomy. N=100

S.No.	Variables	Males	Females	Chi square (x^2)	Df	P value
1	Knowledge			1.25	2	0.53 NS
	Good	1	0			
	Average	27	30			
	Poor	22	20			
2	Attitude			4.74	2	0.09 NS
	Favourable	24	15			
	Moderately favourable	25	35			
	Unfavourable	1	0			

NS = Not Significant (p > 0.05)

Discussion

In this study, From 50 males 22(44%) of the male's knowledge was low while more than half of the males knowledge was average i.e. 27(64%) and only 1(2%) of male had high level of knowledge. Out of 50 females, 20(40%) of the females had low level of knowledge while more than half of the females 30(60%) had average level of knowledge and 0(0%) female had high level of knowledge.

In the present study, 24(48%) of the males had favourable attitude and half of the males 25(50%) had moderately favourable attitude while only 1(2%) of the males had unfavourable attitude. Out of 50 females, less than half of the females 15(30%) had favourable attitude and more than half of the females 35(70%) had moderately favourable attitude and no females had unfavourable attitude. These results were contradictory to the study conducted by[5] **Onasoga, 2013.** The result showed that respondent's knowledge of at least one type of male family planning method, only 18(13.2%) had higher knowledge level and rest of the participants 33(24.3%) had lower knowledge regarding vasectomy. Most of the respondent also showed negative attitude towards vasectomy[5].

The mean knowledge score of males was 7.76+2.33 with obained range of 2-13 and the mean knowledge score with standard deviation of females was also 7.76+2.33; median was 8 with obtained range of 2-13 whereas the mean attitude score of males was 96.26+12.71; median was 96.50 with obtained range of 73-125 and the mean attitude score of females was 97.6+ 12.49; median was 97.50 with obtained range of 76-125. These findings were contradictory to the results of the study by **Gayathry, D., 2014** who observed that females had higher scores as compared to males which was not significant between the overall knowledge score (18.67+7.798 vs. 18.41+7.177)[6].

In the present study, the computed p values of knowledge scores of the males with their selected variables were not significant except education i.e p-value 0.02 and occupation i.e p -value 0.01 which were highly significant. Hence knowledge of males towards tubectomy and vasectomy was dependent on educational status and occupation.

In this study, the computed p values of attitude scores of males with their demographic variables were non significant except Educational status i.e p value 0.00, occupation i.e p value 0.02,No. of children i.e p value 0.05, age at marriage i.e p value 0.03 which were highly significant at the 0.05 level of significance and computed p-value of females with all demographic variables were non significant at 0.05 level of significance. The findings are partially matches with the study conducted by **Onasoga, 2013.** The findings reveals that there was no significant association of academic scores of respondents and their attitude towards vasectomy, as well as between marital status and their attitude towards vasectomy significant association was found between the level of knowledge and attitude towards vasectomy[5].

In the present study, computed p value of males and females with selected variables of knowledge and attitude was non significant at 0.05 level of significance. This shows there is no association between the level of knowledge and attitude of males and females towards tubectomy and vasectomy.

Ethical Approval: The moral leeway was gotten by taking consent from Sarpanch of Respective villages to direct the investigation in the rustic zones. The assent from the qualified Couples was gathered preceding the examination. The reason for doing research venture was clarified and affirmation of privacy was given to the members.

Nursing Intervention for Caregivers of Post Autologous Bone Marrow Transplantation Patients at Home

Asmaa Farouk Mohamed[1], Nawal Soliman[2], Hemat Abd-El-Moneem El-Sayied[2], Asmaa Talaat[3]

[1]M.Sc.N., Community Health Nursing, [2]Professors of Community Health Nursing, [3]Lecturer of Community Health Nursing, Faculty of Nursing-Ain Shams University, Cairo, Egypt

Abstract

Background: Autologous bone marrow transplantation is a curative procedure forhematological diseases and immune deficiencies. The unique and intensive nature of this treatment requires distinctive care during and post the entire transplant course. Nursing intervention for caregivers post autologous bone marrow transplantation patients at home is an important component of the care that improves and develops knowledge and practice of the caregivers, to take care of the patients in order to help them follow the demanding treatment plan to reach recovery.

Aim to evaluate the effect of nursing intervention for caregivers of post-autologous bone marrow transplantation patients at home.

Material and Method: A Quasi-experimental study was carried out among convenient sample of 143 patients and their caregivers who attended the follow up clinic during the first six months post autologous bone marrow transplantation. The study was conducted among patients and their caregivers in three different hospitals Sheikh Zayed Specialized Hospital, National oncology institute, and Nasser institute at outpatient's follow-up clinics. A self-administered questionnaire of patients and their caregivers' demographic data, and reported checklist of caregivers' knowledge and practices toward post-autologous bone marrow transplantation patients at home.

Results: There was a statistically significant difference between pre and post nursing intervention, which indicate improvement in caregivers' knowledge and practice post implementation of the nursing intervention program, and positive correlation between their knowledge and practice.

Conclusion and Recommendations: Although caregivers had adequate knowledge, practice on some aspects, gaps were identified. There is a need for educational interventions and discharge plan to upgrade knowledge and practices of the caregivers of post autologous bone marrow transplantation patient at home.

Keywords: *Autologous bone marrow transplantation, caregivers, nursing intervention, home.*

Introduction

Since the onset and progression of bone marrow transplantation it was evident from the 1950s to early 1960s that nurses play an important role within the multi professional team caring for patients and their families go through this treatment.[1] Bone marrow transplant is an umbrella term for the grouping of a variety of procedures. These transplants use stem cells from bone marrow, peripheral blood or cord blood and more recently the procedure has been called haemopoietic stem cell transplantation (HSCT) The type of treatment is then classified based on the origin of the stem cells, autologous being derived from the recipient himself.[2]

The family does need support, and need pre- and post-HSCT education and psychosocial intervention,. All stages of the transplant process will affect family members. The effect of this severe medical procedure will clearly extend beyond the person concerned to the entire family network.[3] In the post-transplant duration, it is important to have a distinct pattern of evaluation

to assess disease condition and for any post-transplant complications.[4] Increasing caregivers' confidence and competence require training in the skills they need to provide care to the patient. Past studies have repetitively shown that caregivers often express attentiveness in, and have a need for education and support programs.[5]

The population of Egypt exceeded 100 million in 2020. There are fifteen transplant centers and the transplant rate is 8.4 million. Bone marrow transplantation in Egypt began on a restricted scale in 1989. In 1997, the rate of transplantation increased significantly.[6] Specific attention has developed towards educating the long-term survivors and their caregivers in which nursing intervention plays a significant role because medical treatment activities are more in the background and day-to-day questions have to be dealt with.[1]

Research Hypothesis: The nursing intervention program will improve the caregivers' level of knowledge and practices in caring of post Autologous Bone Marrow Transplantation Patients at Home.

Materials and Method

A quasi-experimental study was carried out among 143 patients and their caregivers at outpatient follow-up clinics in three biggest hospitals in Cairo, Egypt for autologous bone marrow transplantation patients, Sheikh Zayed Specialized Hospital, National Oncology Institute, and Nasser Institute. An official written letter including the title and purpose of the study obtained from the dean of Faculty of Nursing, Ain Shams University to the get the approval form directors of the mention hospitals to conduct the study. A consent was obtained from each participant (patient and caregiver).

The 143 (patients and caregivers)were divided into 6 groups The actual process of data collection was carried out in the period from February 2019 to July 2019 The intervention program consisted of 17 hours (5 hours theoretical, 12 hours practical). Educational media were used such as poster, PowerPoint, laptop, handout Arabic booklet, videos.

The tool was developed by the researcher, based on reviewing related literatures and experts' opinions, written in Arabic language, and Completed under supervision of the researcher through group interview. A self-administered questionnaire of patients and their caregivers' demographic data includes 10 questions. Self-Reported checklist of caregivers' practices and knowledge toward post autologous bone marrow transplantation patients at home. Caregivers' Knowledge consisted of 15 questions with Cronbach's value 0.78.

Answers was coded as follow: poor = 1, good = 2. Caregivers' practices consisted of 90 questions including:- patient transfer, Central venous catheter care, Meals preparation and diet restrictions, Personal hygiene, Medication administration, and Following Infection control. With Cronbach's value 0.76.

The total score was divided into two scale: Poor > 60% Good ≥ 60%.

The collected data were organized; tabulated and analyzed using software, the appropriate statistical tests was the Statistical Package for Social Science SPSS (version 25). The statistical analysis includes; percentage (%), Chi-Square test (X^2), Proportion probability P value.

Significance of results was described as follows:

- Not-significant difference obtained at $p > 0.05$.
- Significant difference obtained at $p < 0.0\ 5$.

Evaluation the level of improvement in caregivers' knowledge, practice, was done by giving post-test similar to pre-test. Evaluation was administered to the caregivers after completion of the program in order to estimate the effect of the program on the caregivers, and recognize the benefit of the program and what are the ways of obstacles to lack of implementation.

Results

Table (1) shows that, the median and range of age of the studied patients was 48 (21-50) years, in relation to gender, 53.1% were males, and 67.1% were married, while 58% had 3-4 children, as regards educational level 42% of them had university education. Concerning occupation, 37.8% were employees, with 70.6% had sufficient monthly income.

Regarding the caregivers: Illustrates that, the median and rang of age of the studied caregivers was 47 (18-60)years. 68.5% of the caregivers were females. Regarding Kin-relation with the patient 30.8% were spouse. Related to educational level 41.9 % of the studied sample were secondary education. In relation to the marital status, 41.9% were married, Concerning of job 34.3% were employees, and 76.9% of time of care were full time.

Figure (1) displays that, pre interventional program good knowledge and practice was 27.2%, 36.4%, respectively, while post implementation of an interventional program good knowledge and practice was 87.5%, 89.3% respectively.

Table (2) Clarifies there was statistical significant relation between pre and post of total caregivers' demographic characteristics (age, gender,educational level, occupation, time of care) and total caregivers' knowledge and practice score. However marital status, kin-relation, shows no significant effects on caregivers' knowledge and practice.

Table (3) Illustrates that there was statistical significant positive correlation between pre & post-test of total caregivers' knowledge and practices at $P < 0.001$.

Table (1): Distribution of the patients and their caregivers according to their demographic characteristics (n=143).

Demographic characteristics	Patients	Caregivers
	N (%)	N (%)

Discussion

The current study illustrated that **Table (1)** the median and range of age of the studied patients was 48 (21-50) years, in relation to gender, around half of the patients were males, and about two third were married, while more than half had 3-4 children, as regards educational level less than half of them had university education. Concerning occupation, almost one third were employees, with more than two third had sufficient monthly income. This study was in agreement with previous studies.[7,8]

Regarding the caregivers Illustrates that, the median and rang of age of the studied caregivers was 47 (18-60)years. More than two third of the caregivers were females. Regarding Kin-relation with the patient less than one third were spouse. Related to educational level below than half of the studied sample were secondary education. In relation to the marital status, less than half were married, Concerning of job almost one third were employees, and more than three quarter of time of care were full time. This study was in the consistent with previous studies.[7,9,10] Similar findings also were reported in the studies conducted in USA. Becoming a caregiver was a second full-time occupation, as caregiving had become the priority in their lifetime.[11]

But another earlier study was in contrast to the current study, claiming that young caregivers typically have to juggle jobs, their own family commitments, middle-aged caregivers usually worry about missing workdays. Interruptions in work absence leave and reduced productivity. In addition to, limited income can place families at risk of care for non-compliance or of treatment related decision on the basis of income.[12]

Regarding caregivers' knowledge and practice **Figure (1)** displays that, most of the caregivers had good knowledge, and majority of them had good practice post-interventional program, indicating that the caregivers improved in their knowledge and practice after application of nursing interventional program. This could be because they got benefit of the program, and education outcomes. The level of good knowledge and practice were lower in pre-interventional program as mentioned in early study that Family caregivers often feel unprepared, have inadequate knowledge, and receive little guidance from the transplant team. Beside education should pass expertise, skills and

details. Successful delivery of education is a dynamic process that depends on sufficient timing. The primary outcome identified in the majority of health education. Respondents show increased health awareness and make healthier decisions about their patients' health following intervention. So good education also increases patient/ caregiver self-efficacy, reduces anxiety by planning for transplantation, and increase the satisfaction of the patient. More long- term education results might include improvement in survival and transplantation morbidity, accessibility of health care, willingness of patients/ caregivers to return to work, and quality of life.[12,13] other study revealed that the preparation of family caregivers for their position must include clear education, including skills training. Preparing caregivers should be an ongoing process such that benefits are maintained and education programmes develop as required.[14]

Concerning caregivers' demography **Table (2)** Clarifies there was statistical significant relation between pre and post of total caregivers' demographic characteristics (age, gender, educational level, occupation, time of care) and total caregivers' knowledge and practice score level. However marital status, kin-relation, shows no significant effects on caregivers' knowledge and practice. The finding was supported by other study conducted in USA Indicating that the caregiver does not necessarily discuss the gender position of the participants. This can be explained at least in part by the fact that the majority of caregivers are women, that caregivers themselves are viewed as a woman's position, and that male caregivers make less use of resources, including support groups, than women do.[5]

The same results were observed in early studies that educational and training needs would flow over time, driven by complex processes that characterize adult and family life trajectories. Only a few States provide financial aid to family members who perform the position of caregivers. Therefore, to give full-time care, caregiver has to leave the workforce to support the loved ones. Currently, the Health Care Management System offers some assistance to spouses who perform the function of caregivers.[5,13] With regard to time of treatment. In addition, there were statistically significant differences between the pre-and post-intervention programme, the current research in the same line of the previous study showed that full-time caregivers offer more support and can apply the information acquired by the caregiver from the programme.[14]

There were no major variations in marital status, the relationship of caregivers and their expertise and experience in the current research. The findings show that, in accordance with the previous studies. It reported that there was no significant relation between marital status, and kin-relation of caregivers and their knowledge and practice. This may be due to the nature of the intimate relationship between the caregiver and the patient. It did not rely on the relationship. However, depending on the nature of the relationship between the patient and the caregiver, it could possibly lead to a complicated situation of caregiving that could affect the delivery of care, but did not influence awareness.[5,9,13]

Finally **Table (3)** Illustrates that there was strong positive correlation between pre & post-test of total caregivers' knowledge and practices, the caregivers' total knowledge score was positively associated with the total practice score toward post autologous bone marrow transplantation patients at home. The higher the knowledge, the higher the practice, in which this shows that caregivers' practice is directly related to their knowledge as reported in the previous study[12,13] In the most recent sense, a similar study was performed in the United States, which determined that there is a substantial association between the degree of education of caregivers and their practice in post-autologous bone marrow transplantation patients. Improved awareness and/or willingness to offer treatment to United States.[12] In other previous study mentioned that Role preparedness has been studied in terms of how the development of knowledge and skills might protect the caregiver from role distress when the difficulty of care or the need for care is high.[9]

Conclusion

Based on the results of the current study and research hypothesis;implementation of nursing intervention program improved the knowledge and practices of the caregivers of post autologous bone marrow transplantation patients at home,there was statistically significant differences between pre/post-nursing intervention post autologous bone marrow transplantation regarding caregivers' knowledge, practice. In addition, there was statistically significant relations between caregivers' demographic characteristics and total score level of caregivers' knowledge and practice in some parts, beside there was positive correlation between pre & post-test of total caregivers' knowledge and practices score level. Further research with a larger sample of caregivers

from other governorates in Egypt are required in order to have a better understanding the needs of caregivers' knowledge and practices post autologous bone marrow transplantation patient at home.

Abstract

The COVID-19 is a globally problem influences in all function of life, from health to economic and political of countries. It is still to elevated in incidence and killed people specially among health workers. The study aimed to assess the psychological problems among health workers who work in health facilities at Babylon Province.

Descriptive-analytic study conducted during the era of COVI-19 by using online GHQ-12 items as instrument to measure the symptoms of psychological problems. Convenience sample included 220 health workers participated in the study. The study revealed elevated in psychological problems among health workers and found significant relationship between gender and psychological problems. The study concluded to the support and available the enough training and medical health equipment may be reduced it.

Keyword: *Psychological problems, health workers, pandemic Covid-19.*

Introduction

The COVID-19 is a global outbreak is a highly contagious and it is main cause of respiratory illness.[1] It is a viral infection recognized by fever, shortness of breath, cough and chest infection.[2] First detect to it in Wuhan, China[3], and rapidly spread in all world yet[1]. But COVID-19 is becoming an increasing public event being a rapid epidemic [4]. The World Health Organization states in the official website (March, 2020), there is 100,000 person and more are diagnosed with COVID-19 infection around of world [5]. So that any person can be affected emotionally and exposure to psychological problems symptoms during of the COVID-19 now. Most communities and people had overwhelming feelings of fear, stress and anxiety about a COVID-19 disease [6], but there is evidence reported to proof the health workers are effected by the psychological problems after the COVID-19 reach to the maximum point such as stress, anxiety, insomnia and other health problems. [7] Everyone responds to stressful circumstances and reacts differently according to experiences, abilities to adapted with it and how coping with emotional distress [8] due to the highly risks of exposure or ethical dilemma and stress of workload and work hours [9,10, 11].

Sadly, some healthcare workers can face rejection because of stigma or fear by their families or friends, so it may be make them which is a victim and increased the psychological problems on them [12].

The study goals to assess the symptoms of psychological problems among the health workers during pandemic Covid-19 at Babylon Province and find out the relationship between their characteristics and the symptoms of psychological problems among them .

Material and Method

The descriptive-analytic study design conducted at A Nonprobability convenience sample was conducted in

Babylon Province during the era pandemic Covid-19 in world generally and in Iraq especially from 20 March to 5th April 2020 by using Google samples forms online to self-reported questionnaire distributed on 220 participants (57 female and 163 male) from general health workers (24500) were work in all health care facilities in Babylon Province (see table (1)). After get consent to participated in study. The study sample is a non-probability convenience sample, included participants from all governmental health facilities of Babylon Province weather worked in isolated facilities of COVID-19 or in another governmental health facilities.

The study questionnaire had two parts. Part one related to demographic characteristics of health workers like age, gender, experiences duration with contagious diseases, level education, marital status. Part two related to General Health questionnaire (GHQ12-items) to explore the psychological problems in health workers who are not have psychological problems by self-reported. The questionnaire is translated and use in Al-Hamoody study (2019)[13] and before him it used for first time by Goldberg (1970) was use GHQ to assess psychological well-being. It has four scores (0-3) begin from much less than usual to better than usual. It has cutoff point 1.5, when a person had ≥ 1.5 that mean had psychological distress. This scale is a common used in primary health care setting.

The researchers are used descriptive statistics to describe the results of data and determine the achievements of the study goals or not by using computer programs (SPSS v.17 and Microsoft Office Excel (2010)) to reveal the results.

Results

Table (1): Total number of health workers in the health facilities at Babylon Province

Discussion

Most of health workers are participated in study are males (74%) and their aged less than 30 years old (68%) and had bachelor degree (44%) (table 2). About (65%) of participants are married and not had child (50.1%) and they are not worked previously in isolated places or practical skills with epidemic diseases (84%) (table (3)). In table (4) revealed the Level of general mental health of participants in the study according the items of general health questionnaire (GHQ-12 items) who work in health facilities at Babylon Province, but generally, half health workers are participated in study had highly incidence levels of psychological problems during the COVID-19 virus (table 5). Therefore, these result considered as a risk indicator if it is not treated and can be increased among them. These result consent with result of Zhang study (2020)[1]. These the problems had a significant complication and impairment in social and occupational functioning; and feeling overwhelmed by the demands of everyday life on them [5]. The reasons for the psychological problems may be attributed to the many factors such as the initially inadequate awareness about COVID-19 and knowledge about how prevent it and control, as well as long-term of workload, and lack the medical protective equipment. In table (6) the researchers find significant relationship between the psychological problems and gender of health workers [8] may due to the nature of male from female by how adopting and coping with the stress and events.

The researchers concluded to increase in psychiatric problems among health workers and may be elevated if it is not treated correctly. Decrease stigma, encouragement and training about how to reduce and faces stresses are very important. Finally, the support and available the medical equipment is important items to decrease the psychological problems on them.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: After the administrative arrangements are completed, acceptance of health workers participants was sought for after explaining to them the aim of the study and inform them that all the information taken will be treated confidentially and it is for research purposes only,then taken the consent from them to participate in this study. Also, an ethical approval was obtained from ethical committee of research in Faculty of Nursing University of Kufa regarding confidentiality and anonymity of participants.

Helicobacter Pylori-Associated Iron-Deficiency Anemia and Interleukins Effect

AthraaRazaq Mohammed Hindi[1], Oday MitibHadi[2]

[1]Research Scholar, College of Health and Medical Techniques, Al-Furat Al-Awsat Technical University, Al-Najaf, Al-Kufa, Iraq, [2]Professor, Corresponding Author, College of Health and Medical Techniques, Al-Furat Al-Awsat Technical University, Al-Najaf, Al-Kufa, Iraq

Abstract

Helicobacter pylori (H. pylori) is a highly prevalence microbial infection, that acts as an iron stressor in susceptible individuals the relationship between ferritin and cytokine levels in individuals infected with H. pylori remains controversial. Based on serology testing for anti-H. pylori IgG, participants (70 seropositive and 70 seronegative aged 30-60 years were enrolled. Serum iron profiles including iron, ferritin, and total iron-binding capacity, were measured. IL-1β and IL-6 serum levels were compared. The mean value of interleukin 1beta (IL-1β) level of patients and controls revealed that H. pylori patients had a significantly higher at ($P< 0.001$) mean of (IL-1β) when compared to the controls, as shown in this study there is positive correlation between gastric interleukin 1beta (IL-1β) and iron deficiency anemia (IDA) blood parameters observed in resent study could be due to the powerful capability of IL-1β in inhibiting gastric acid secretion. The mean value of Interleukin-6 (IL-6)) level of patients and controls revealed that H. pylori patients had a significantly higher at ($P< 0.001$) mean of (IL-6) when compared to the controls.

Keywords: *Helicobacter pylori, iron deficiency anemia, interleukins.*

Introduction

Helicobacter pylori is a spiral-shaped, Gram-negative bacterium that is responsible for infections affecting more than half of the world's population and is currently known to play a causative role in the pathogenesis of chronic gastritis, peptic ulcer diseases, gastric cancer and mucosa-associated lymphoid tissue lymphoma[(1)]. *H. pylori* is recognized as the most common cause of chronic active gastritis and is also an important pathogenic factor in peptic ulcer disease. The outcome of infection is thought to be related to severity and distribution of *H. pylori*-related inflammation[(2)]. Biological factors that affect clinical outcome in *H. pylori* infection have been widely studied. In addition to bacterial virulence determinants in *H. pylori* strains, immunological factors in the host are likely to play a crucial role in different clinical expression of *H. pylori*-infection[(3)]. *H. pylori* infection first induces neutrophilic gastritis, which progresses to chronic gastritis in most people . Activation and migration of these inflammatory cells into the gastric mucosa is related to increased production of proinflammatory cytokines, including IL-8, IL-1β, TNF-α and IL-6 which are believed to contribute to maintaining the gastric inflammation and causing epithelial cell damage[(4)]. the inflammation that may happened in the stomach and proinflammatory cytokines lead to anemia, Anemia induced by digestive diseases refers to anemia due to iron deficiency. Conventional gastrointestinal diagnostic workup fails to establish the cause of iron deficiency in about one third of patients[(5)]. Recent meta-analyses indicates H. pylori eradication results in improved iron status of children and adults with ID/IDA compared with iron therapy alone, this suggests underlying changes in gastric inflammation,

Corresponding Author:

Research Scholar, College of Health and Medical Techniques,Al-Furat Al-Awsat Technical University, Al-Najaf, Al-Kufa,Iraq
e-mail: kuh.aud@atu.edu.iq

or infection-related perturbations in gastric physiology may contribute to ID in H. pylori infection[6]. H. pylori infection is also associated with marked reduction in gastric juice ascorbic acid, which binds to reduced ferrous iron facilitating iron transport and uptake. In adults, hypochlorhydria in H. pylori-associated corpus atrophy has a role in ID through changes in physiology of iron-complex absorption. Although H. pylori is acquired early in life[7]. In western countries there are only some uncontrolled intervention studies showing recovery from anaemia after *H. pylori* eradication. *H. pylori* infection has been considered as a risk factor for IDA. The British Society of Gastroenterology recommends eradication of *H. pylori* infection in patients with IDA and normal colonoscopy and oesophagogastroduodenoscopy[8].

Materials and Method

The study is conducted on the Helicobacter pylori patient in digestive system center at (Al-Sadder Hospital) in Najaf province-Iraq from February to August 2019. A total of 70 H. pylori infected individual divided into two groups: males and females (males 45 and females 25) were enrolled in this study. Their ages ranged from (30 to 60) years. They were diagnosed by specialist physicians depending on the clinical features, family history and confirmed by laboratory analysis of H. pylori stool antigen. A specific questionnaire was designed to both patients and control groups.

Helicobacter pylori stool antigen test (HpSA) is noninvasive diagnostic modules for diagnosis of Helicobacter pylori (H. pylori) infection. SAT based on enzyme immunoassay was used to identify the infection as follows: the HpSA test used in this study is based on a sandwich enzyme immunoassay (EIA) and uses microtiter plates coated with polyclonal rabbit anti-H. pylori antibodies as the capture antibody and a second antibody to H. pylori, labeled with peroxidase. The minimal concentration of H. pylori determined by this kit was <0.015 mg/g of stool. The optical densities at 450 nm for negative and positive controls were <0.200 and >1.000, respectively, and the cutoff value was defined as the negative control value + 0.200[9].

Five milliliters (ml) of blood were withdrawn by vein puncture from Helicobacter pylori patients and healthy control. A tourniquet was applied directly on the skin around the arm, the skin over the vein was sterilized with 70% ethyl alcohol, then blood was collected by syringe divided into two aliquots. The first (2 ml) was added to anticoagulant containing tube (EDTA tube) for estimation of hemoglobin and packed cell volume and the second (3 ml) was put in serum separating tube (SST) which also known as gel tube, to be allowed to clot at room temperature for 15-20 minutes, and then it was centrifuged for 5 minutes at 5000 route revolution per minute (rpm), to get the serum. The separated serum was transferred into plain tube and storage it at -20 ºC until being used in ELISA test[10].

Ten micro liters (µl) of the EDTA blood sample was placed in the aspirator on the instrument Mindray BC-60s. EDTA, ethylene diamine dihydrochloride; CBC, complete blood count; Hb, hemoglobin; MCV, mean corpuscular volume; MCH, mean corpuscular volume, MCHC, mean corpuscular volume concentration, HCT, *hematocrit test*. All these test where done to evaluate the anemia(Iron deficiency anemia).

Iron, FER, serum ferritin, TIBC, total iron binding capacity, TRANS, transferrin, were used to determine the type of anemia.

IgG immunoglobulin glass G, |IL- 1β, interleukin1 beta, IL-6, interleukin 6, our studies focused on the relationship between bacteria and anemia by levels of interleukin and how effects on hepcidin production.

Data of the study participants, Helicobacter pylori patients and controls, were entered, managed and analyzed using the Statistical Package for Social Sciences (SPSS) version 25 software for windows, IBM, US, 2017. All variables were checked for errors or inconsistency prior to the analysis process. Continuous variables included the age, Hb, PCV, WBCs count, RBCs count, MCV,MCH, iron, ferritin, TIBC, transferrin, IL-1β, IL-6 and IgG titer were tested for statistical normality distribution using histogram and normal distribution curves and they all appeared to follow the statistical normal distribution. Chi-square test was used to assess the significance of differences in the frequencies of categorical variables between H. pylori patients and controls. (ANOVA) F test used to compare mean levels of these parameters across the age groups. Level of significance (P. value) of 0.05 or less considered significant. Finally, results and findings presented in tables and or figures accordingly, using the Microsoft Word application 2010 for windows .

Results

The result of immunoglobulin G (IgG) level of

patients and controls revealed thatH. pylori patients had a significantly higher at (P< 0.001) mean of IgG when compared to the controls**;** it was found that interleukin 1beta (IL-1β) level of patients and controls revealed that H. pylori patients had a significantly higher at (P< 0.001) mean of (IL-1β) when compared to the controls**;** The mean value of Interleukin-6 (IL-6)) level of patients and controls revealed that H. pylori patients had a significantly higher at (P< 0.001) mean of (IL-6) when compared to the controls **.**

Table (1): Comparison of mean values of Immunoglobulin G(IgG), Interleukin -1β and Interleukin-6 of Helicobacter pylori patients and controls

Parameters	Group				t-test df = 138	p- value
	Patients (n-70)		Control (n=70)			
	Mean	SD*	Mean	SD*		
IgG pg/ml	53.78	9.7	3.46	1.5	42.71	<0.001 sig
IL-1β pg/ml	83.24	17.02	32.79	7.86	22.50	<0.001 sig
IL-6 pg/ml	565.49	177.48	72.01	14.91	23.18	<0.001 sig

Discussion

The mean value of immunoglobulin G (IgG) level of patients and controls revealed thatH. pylori patients had a significantly higher at (P< 0.001) mean of IgG when compared to the controls, as shown in table (1) [(11)]. Serum anti-H. pylori IgG titer was measured using ELISA, subjects with high Hp-IgG antibody titer have a high H. pylori density some studies suggest that the high density of H. pylori[(12)].

The mean value of interleukin 1beta (IL-1β) level of patients and controls revealed that H. pylori patients had a significantly higher at (P< 0.001) mean of (IL-1β) when compared to the controls, as shown in table (1) . There is positive correlation between gastric interleukin 1beta (IL-1β) and iron deficiency anemia (IDA) blood parameters observed in resent study could be due to the powerful capability of IL-1β in inhibiting gastric acid secretion[(13)] . The mean value of Interleukin-6 (IL-6)) level of patients and controls revealed that H. pylori patients had a significantly higher at (P< 0.001) mean of (IL-6) when compared to the controls, as shown in table (1) .

Inflammation has a potent effect on iron homeostasis, by reducing intestinal iron absorption, and sequestering iron in macrophages, thereby decreasing serum iron levels. There is now substantial evidence that these effects of inflammation are also mediated by hepcidin. Hepcidin is a 25-amino acid peptide hormone secreted by hepatocytes that circulates in blood plasma and is excreted in the urine . Hepcidin inhibits intestinal iron absorption, iron recycling in macrophages, and release of stored iron from hepatocytes, thereby decreasing body iron availability[(14)].

Conclusion

From the present study, we can conclude that Helicobacter pylori patients are at high risk for iron deficiency. There is statistically significant positive correlation was noticed between interleukin-6 and interleukin-1 beta and iron store that cause iron deficiency anemia. The levels of interleukin-6 and interleukin-1beta in patients with Helicobacter pylori, these parameters work directly on hepcidin level which in turn affects on ferritin.

The Influences of Antenatal Care, Postnatal Care and Early Initiation of Breastfeeding on an Exclusive Breastfeeding Pattern in the Working Area of Manukan Kulon Public Health Center at Surabaya City

Azizi Pridasari[1], Lutfi Agus Salim[2]

[1]Bachelor Student in Department Biostatistics and Demography, Faculty of Public Health, Universitas Airlangga, Surabaya, Indonesia, [2]Associate Professor in Department Biostatistics and Demography, Faculty of Public Health, Universitas Airlangga, Surabaya, Indonesia

Abstract

Exclusive breastfeeding is very important for babies to maintain their immune system, brain intelligence, emotion stability and to protect babies from various diseases that are causes of death. Breastfeeding will also benefit the mother, which will reduce blood loss during menstruation, restore maternal weight as before pregnancy, reduce the risk of breast cancer, and uterine cancer. The purpose of this study was to determine the influences of antenatal care, postnatal care and early initiation of breastfeeding on an exclusive breastfeeding pattern. The samples used in this study were mothers who had babies aged 7-12 months in June to August 2018 as many as 48 respondents in the working area of Manukan Kulon Health Center in Surabaya. This study used the descriptive and bivariate analyses. The obtained results were antenatal care (p = 0.001), postnatal care (p = 0.002) and early initiation of breastfeeding (p = 0,000). During pregnancy the majority of mothers make complete antenatal care visits with a frequency of 10 times, antenatal care is very important for mothers, especially the pattern of breastfeeding. In addition to the importance of antenatal care visits, mothers who have given birth and are entering the postnatal care phase are required to make postnatal care visits. Socialization from health workers and the support of closest people are required in order to achieve the exclusive breastfeeding.

Keywords: *Exclusive Breastfeeding, Early Initiation of Breastfeeding, Antenatal Care, Postnatal Care.*

Introduction

Exclusive breastfeeding is the provision of breast milk that is given to infants without giving any additional food and drinks to the baby until the age of 6 months and given the breastfeeding as early as possible (1). Breast milk as the main food of babies is very important because breast milk contains 60% of the nutritional needs of babies. Breast milk has several benefits including the intelligence of baby's brain, the baby's emotion stability and can protect the baby from various diseases that are causes of death. Breastfeeding will also benefit the mother, which will reduce blood loss during menstruation, restore maternal weight as before pre-pregnancy and reduce the risk of breast cancer and uterine cancer. Although breastfeeding and breast milk are very beneficial, it is estimated that 85% of mothers in the world do not give an exclusive breastfeeding as recommended by WHO (2002). Many mothers in many countries do not provide exclusive breastfeeding due to various factors such as social, cultural, economic and political(2).

Breastfeeding can affect the reduction in newborn mortality from the first day of birth by 16% and will reduce death possibility by 22% if the newborn is given breast milk within the first hour after birth. In 2012, the 0-5 month's infants received exclusive breastfeeding with the percentage of 41.5%. In 2013, infants who received exclusive breastfeeding were 38%. In 2014, the coverage of exclusive breastfeeding in Indonesia did not meet the strategic plan target of 52.3% while the target to be achieved was 80%. However, in 2015, the national target of exclusive breastfeeding was reduced to the amount of 39% so that the national target was able to be reached.

In 2016, the results of nutrition monitoring in Indonesia showed that newborns received early initiation of breastfeeding with the percentage of 51.9%. The infants who were aged 0-5 months received an exclusive breastfeeding with the percentage of 54%, while infants who were aged 0-6 months get exclusive breastfeeding by 29.5%. On these results, it can be concluded that babies received a complementary food of breastfeeding at the age of 5 months on average.

According to the Isrono study in 2013, mothers who gave exclusive breastfeeding in the working area of Serpong Public Health Center were as much as 14.6% [3]. In conclusion, the information that has been given and obtained were not necessarily going to be implemented properly.

Methodology

The samples used in this study were mothers who had babies aged 7-12 months in June to August 2018 as many as 48 respondents. The technique used in this study was by carrying out the data retrieval in the working area of Manukan Kulon Public Health Center at Surabaya City by using the simple random sampling formula.

The dependent variable in this study was the pattern of exclusive breastfeeding. Meanwhile, the independent variables in this study were the influence of antenatal care, postnatal care and early initiation of breastfeeding.

Data analyses in this study were using descriptive and bivariate analyses. Descriptive analysis was used to describe the characteristics of each independent and dependent variables. Meanwhile, bivariate analysis was used to see the relationship between each independent and dependent variables using a logistic regression analysis. Through the logistic regression test, the value of p would be obtained, which in this study used a significance level of 0.05. Research between the two variables was said to be meaningful if it had a value of $p < 0,05$ which meant Ho was rejected and H1 was accepted. It was said to be meaningless if it had $p >= 0,05$ which meant that Ho was accepted and H1 was rejected. Bivariate analysis was carried out to select candidates for influential factors.

Results

Antenatal care is a midwifery service for pregnant women that aims to maintain the health of pregnant women and ensure normal birth can be carried out at least four times during pregnancy to confinement. Antenatal care visits are grouped into 2 groups, namely complete and incomplete antenatal care visits. Research result shows that the majority of respondents made a complete antenatal visit from the beginning of the pregnancy to giving birth with a total of 44 people (91.6%). Respondents who had an incomplete antenatal care visit were as many as 4 people (8.4%) with a frequency of 4 time visits.

Postnatal Care (PNC) is the period after the placenta is born and the period ends when the uterus organs returns to its pre-pregnancy state. At this time, the body is making both physical and psychosocial adjustments to the birth process that starts immediately after the placenta is born until the body can adjust to perfection and ends when the uterine organs return to their pre-pregnancy state which lasts for 6 weeks. Research result shows that all respondents take the postnatal care visit after giving birth, although with different frequency of visits. The most postnatal care visit was 2 times with a percentage of 60.4%, followed by postnatal care visits as much as 3 times by 31.3% and the least was one time postnatal care visit with a percentage of 8.3%. The percentage was very good because postnatal care visits were suggested to be done at least once after giving a birth.

The coverage of early initiation of breastfeeding among respondents in the working area of Manukan Kulon Public Health Center at Surabaya can be categorized as good, because most respondents initiated early breastfeeding immediately after the baby was born with the percentage of 91.7% and 8.3 % did not initiate early breastfeeding.

Table 1. Distribution of Breastfeeding Pattern Based on Ante Natal Care (ANC) Visits

ANC Visit	Breastfeeding Pattern				Total	
	Exclusive		Non-Exclusive			
	n	%	n	%	N	%
Complete	4	9,1	40	90,9	44	100,0
Incomplete	0	0,0	4	100,0	4	100,0
Total	**4**	**8,3**	**44**	**91,7**	**48**	**100,0**

Distribution results on the pattern of breastfeeding based on Antenatal Care visit in the table 1 shows that most respondents with complete ANC visits gave breastfeeding with a non-exclusive pattern with a percentage of 90.9% while respondents who did not routinely make ANC visits gave breastfeeding with a non-exclusively pattern by 100%.

Table 2 Distribution of Breastfeeding Pattern Based on Post Natal Care (PNC) Visit

PNC Visit	Breastfeeding Pattern				Total	
	Exclusive		Non-Exclusive			
	n	%	n	%	n	%
1 Time	0	0,0	4	100,0	4	100,0
2 Time	4	3,18	25	86,2	29	100,0
3 Time	0	0,0	15	100,0	15	100,0
Total	**4**	**8,3**	**44**	**91,7**	**48**	**100,0**

Based on the results in table 2, the majority of respondents visited Postnatal Care twice with a frequency of 29 respondents. The respondents who visited PNC twice and determined the pattern of non-exclusive breastfeeding had a lower percentage with a total of 86.2%. Meanwhile, the respondents who visited PNC once and three times and determined the pattern of non-exclusive breastfeeding to their babies had a greater percentage by 100% respectively.

Table 3 Distribution of Breastfeeding Pattern Based on the Early Initiation of Breastfeeding (EIB)

EIB	Breastfeeding Pattern				Total	
	Exclusive		Non-Exclusive			
	n	%	n	%	n	%
Yes	4	9,1	40	90,9	44	100,0
No	0	0,0	4	100,0	4	100,0
Total	**4**	**8,3**	**44**	**91,7**	**48**	**100,0**

The pattern of breastfeeding based on Early Initiation of Breastfeeding in table 3 shows that there were more respondents who did the EIB than those who did not. Respondents who did EIB mostly gave non-exclusive breastfeeding to their babies with the percentage of 90.9%. Meanwhile, the respondents who did not give an EIB tended to give a non-exclusive breastfeeding to their babies with a percentage of 100%. The analysis of the independent and dependent variables by using logistic regression analysis (a = 0,05) are as follows.

Table 4 Bivariate Analysis of Antenatal Care, Postnatal Care and Early Initiation of Breastfeeding

Variable	Sig	Explanation
Antenatal Care	0,001	Significant
Postnatal Care	0,002	Significant
Early Initiation of Breastfeeding	0,000	Significant

Based on table 4, the logistic regression analysis obtained, there were 3 variables that influenced the pattern of breastfeeding to mothers, namely antenatal care (p = 0,001), postnatal care (p = 0,002) and early initiation of breastfeeding (p = 0,000).

Discussion

Antenatal Care Factor: Antenatal care is a health service for a mother during her pregnancy which carried out in accordance with established antenatal care standards. The visit of pregnant women to health services is recommended as follows; once in the first quarter, once in the second quarter and at least 2 times in the third quarter[4]. Ideally, every woman who is pregnant wants to have a pregnancy check in order to detect abnormalities that exist or will arise in the pregnancy are quickly identified and can be addressed immediately before affecting the pregnancy by conducting antenatal care checks[5].

The results show that the respondents who did a complete antenatal care visit were as much as 91.6% while the respondents who did not make a complete antenatal visit were 8.4%. The results of the study show that most respondents were aware of the importance of maintaining pregnancy [6].

According to the Indonesian Ministry of Health (2012), ANC visits of pregnant women are influenced by several factors[7]. The factors are including internal factors such as parity, mother's age and also external factors such as mother's knowledge, attitudes, socioeconomic conditions, socio-cultural, geographical, information and also the support from both staff and family[8].

The results show that the majority of respondents with a percentage of 91.6% made a complete ANC visit, the respondents who gave exclusive breastfeeding by 9.1% and while the respondents who gave non-exclusive breastfeeding were at 90.9%. This study was in line with a research conducted by Suparmi and Ika (2012) which stated that ANC visits affect the increase in the scope of exclusive breastfeeding [9].

Postnatal Care Factor on Breastfeeding Pattern: Postnatal care is a series of treatments performed for postpartum mothers including massages, breast care, oxytocin massage, postpartum spa and so on. Postnatal care is done so that the puerperal mother can pass through the puerperium phase well without any complications[10].

The purpose of the postnatal care visit is to take care of the health of both mother and baby, both physical and psychological, to treat the patient if any complications occur, provide health education regarding self-health care, nutrition, breastfeeding, provide information to the baby and care for healthy babies and providing family planning services [11].

The results show that the respondents who routinely visited postnatal care once were 8.3%, while those who did postnatal care visit twice were 60.4% and the respondents who visited postnatal care three times amounted to 31.3%. The distribution of PNC visits is positively related to the pattern of breastfeeding. Most respondents with a total of 86.2% with the frequency of PNC visits as much as twice decided to do the breastfeeding with a non-exclusive pattern.

The results show that postnatal care visits affect the pattern of breastfeeding. This study was in line with the research conducted by Seid et.al (2013) in Bahir Dar City Administration, Northwest Ethiopia which stated that there was a relationship between the amount of PNC visits with the exclusive pattern of breastfeeding [12].

Early Initiation of Breastfeeding (EIB) Factor on Breastfeeding Pattern: Early Initiation of Breastfeeding (EIB) which stands for early initiation of breastfeeding, is the baby's active effort to suckle within the first hour of birth, both normal and cesarean deliveries. The baby is placed on the mother's abdomen and chest immediately after birth and given the opportunity to start breastfeeding herself or himself by crawling for beasts and letting the baby's skin contact with her mother for an hour. On the first hour, the baby finds his mother's breasts in the beginning of a "life-sustaining between mother and child." The World Health Organization (WHO) recommended early breastfeeding to be initiated within the first hour after the baby is born by placing the baby in the mother's chest as soon as the baby is out of the birth canal[13].

The results of this study indicate that respondents who did an EIB were as many as 91.7%, while the respondents who did not do the EIB were 8.3%. In conclusion, most mothers have understood the importance of EIB for babies. The analysis shows that EIB has a big influence on the pattern of breastfeeding. This study was in line with the study of Pongtuluran, et.al (2017) who stated that there is a relationship between EIB and exclusive breastfeeding patterns[14].

Conclusion

During their pregnancy, majority of mothers make complete antenatal care visits with a frequency of 10 times, antenatal care is very important for mothers, especially the pattern of breastfeeding. In addition to the importance of antenatal care visits, mothers who have given birth and are entering the postnatal care phase are required to make postnatal care visits. Most of the mothers did a two times postnatal care visit and the postnatal care visit in this study had a major influence on the pattern of breastfeeding.

The coverage of mothers who initiate breastfeeding early in their babies after birth (EIB) can also be categorized as good. Therefore, the early initiation of breastfeeding has an influence on the pattern of breastfeeding.

Suggestion: For couples who are going to get married are required to take counseling at a public health center or a hospital to educate themselves regarding the preparation that will be done after marriage and after they have children. Counseling can also increase the mother's knowledge, one of which is the importance of breastfeeding for infants. In addition, health workers also provide education on how to treat breast nipples and injured breasts during breastfeeding.

Medico-Legal Updates of the Adverse Threat of Cigarette Advertisements on Children

Bambang Eko Turisno[1], IGA Gangga Santi Dewi[1], Suharto[1], Ery Agus Priyono[1]

[1]*Lecturer at Faculty of Law, Diponegoro University, Indonesia*

Abstract

Advertising is an integral part of modern business activities. Information on ad serving in the form of true, clear and honest information about the condition and guarantee of goods is a consumer right that must be given by business actors. In Indonesia, cigarette advertisements in laws and regulations limit and provide several conditions. Some cigarette advertisements do not meet the conditions. The results showed that cigarette advertisements include, visual, tagline, images, placement, airtime, and content of advertisements using psychological persuasion, targeting the share of adolescents and children, who play a role in the onset of cigarette use, encouraging young people to start smoking that threatens children and teenagers.

Keywords: *Medico-legal aspects, cigarette, advertisements, adverse effect, children.*

Introduction

Advertising is an inseparable part of modern business. This fact is closely related to the way of modern industrial production which produces products in large quantities, so it must find a buyer. Advertising primarily intends to provide information on the products produced that are expected to be effective, so that products or services are in demand in the market. Gov. Reg No. 19/2003 concerning Amendments to Gov. Reg No.81 of 1999 concerning Safeguarding Cigarettes for Health, stated that cigarette advertising is an activity to introduce, promote cigarettes with or without rewards to the public with the aim of influencing consumers to use the cigarettes offered. Advertising can be divided into two functions, namely the informative function and the persuasive function. In reality there are no ads that are merely informative and no ads that are merely persuasive. However, there are advertisements with more dominant information elements, and advertisements with the most striking promotional elements. Providing true, clear, and honest information about the conditions and guarantees of goods and/or services as well as providing an explanation of the use, repair and maintenance specified in Article 7 (b) of the Consumer Protection Act is the obligation of business actors. Information that is true, clear, and honest about the conditions and guarantees of goods and/or services according to Article 4.1 is the consumer's right. Business actors have the obligation as stipulated in Article 7 to have a good intention in carrying out their business activities.

Cigarette advertising can only be done with certain requirements. The public knows that smoking can have negative effects, although on the other hand some people still consume it. The prevalence of active smokers in Indonesia is increasing very fast. Cigarettes contain an addictive substance which if inhaled can endanger health for individuals and society. Each cigarette contains nicotine and tar which are substances, compounds or substances that are addictive and carcinogenic.Forms of cigarette advertisements are widely displayed on billboards, print media and television media. A number of cigarette advertisements, targeting the share of teenagers and children, groups of children and adolescents are very vulnerable to advertisements because they can create

e-mail: bambangekoturisno@live.undip.ac.id

models that are imitated and form inappropriate dreams. Advertising, promotion, production requirements and sales of cigarettes, the settings have not been determined to the maximum. The study discusses the protection of children in cigarette advertisements which include, how the contents of cigarette advertisement loading in Indonesia and how children protect against cigarette advertisements.

Research Method: The approach method used is classified as empirical juridical and analytical descriptive research specifications, and qualitative analysis is also used. Data collection includes records, documents, articles and clippings from the mass media as well as data obtained by looking at the legislation and relevant literature. The data was also obtained directly through observations in the field observations, which were carried out directly at the research location which included brochures, banners, cigarette billboards, and cigarette advertisements on television.

Cigarette Advertisements in Indonesia: Most countries impose regulations on advertising practices. In general, industry regulations and laws in many countries are aimed at protecting companies from unfair competitive attacks[1]. Regulation is also to protect consumers against false and misleading advertising. Consumers must be protected from wrong business practices and their ignorance. Promotional activities according to Article 1.6 Law No. 8/1999 concerning Consumer Protection as an activity for introducing or disseminating information on goods and/or services to attract consumers to buy goods and/or services to be traded, is giving obligations to business actors in Article 7 to have an intention good at doing business. Obligations of business actors specified in Article 7 (b), namely to provide true, clear and honest information about the conditions and guarantees of goods and/or services and to provide explanations for the use, repair and maintenance. Information that is true, clear, and honest about the conditions and guarantees of goods and/or services according to Article 4.1 is the consumer's right.

In Indonesia, the advertising material as Article 17 Gov. Reg. No. 19 of 2003 concerning Amendments to Gov. Reg. No. 81 of 1999 concerning Safeguarding Cigarettes for Health determines that it is prohibited to stimulate or encourage people to smoke, illustrate or suggest that smoking provides health benefits, display or illustrate in the form of pictures, writing or a combination of both, cigarettepackets, cigarettes or people who are smoking or point to people who are smoking, aimed at or displaying in the form of pictures or writing or a combination of both, children, adolescents, or pregnant women, to name the product concerned of cigarettes, and be contrary to the norms prevailing in society.

Cigarette advertisements and protection for children: A report from the US Department of Health and Human Services shows that if a person does not start smoking until past the age of adolescence, he will not start smoking. of the adults who had smoked, 88% lit their first cigarette at the age of 18, and more than 44% were accustomed to smoking at that age. Some studies demonstrated that the younger a person starts smoking, the higher the likelihood of someone becoming a heavy smoker[2,3,4]. Furthermore,Bezilla, George and Gallup International Foundation show that seventy percent of teenagers who smoke regret their decision and 66% want to quit smoking[5].

Cigarette marketing is important to encourage young people to start smoking[6,7]. Teinowitzstated that exposure to advertisements and other forms of marketing communication played a role in the beginning of the use of tobacco products and 90% of smoking habits started with teenagers, according to the Institute of Health and Human Services in his research. The results of a Pollay et al, showed that brand advertising significantly influences brand selection, especially in young people[8]. Tobacco brands are more often associated with positive images than producer names. Advertising spending to increase market share is dedicated to developing brand identification and preferences rather than developing producer identification. Consumers identify and buy tobacco products through brand names instead of producer name. A number of cigarette advertisements, targeting the share of teenagers and children, not adults. The selection of media and inappropriate broadcast time tagged a number of cigarette advertisements including 'just enjoy it, and, 'no you are not crowded', targeting the share of teenagers and children, not adults. Therefore cigarette advertising is considered detrimental to children and adolescents. Cigarette advertisements display cigarette brands by including the price of cigarettes per stick, the aim is to make it easier for children to calculate the money they have to buy cigarettes.

Groups of children and adolescents are very vulnerable because advertising can create models that are imitated and form inappropriate dreams. As a visual

media, television can show something that creates a false impression through optical illusions or similar means. The strength of TV is the demonstration ability. This TV is a champion in marketing, because this media allows people to see products or services plus the demo, in an easy way. Delivered in an advertisement, one of the functions of cigarettes is to show males. Cigarettes are a man's male identity[9]. With a cigarette he feels as male as a cowboy warrior, while riding a gallant horse or associated with super busy executive work while inhaling puffs of smoke that are said to contain nuclear material. Cigarette advertisements featuring masculinity as illustrated in a contest of courage through adventure. As a result, men want to smoke to the point of smelling to show their masculinity, the assumption will be awesome when smoking. The creation of psychological consumer desires, one's desire for goods that "makes him feel personal achievement, promises social acceptance". According to John K. Galbraith, quoted by Velasquez is a manipulative advertisement[10].

Warning of the dangers of smoking contained in cigarette advertisements, Fox et al, put forward some of the results of the study as follows[7]. First, Pollayand Strasburger et al,research cited young people as being far more sensitive to advertising than adults[11,12]. Young people are easily persuaded by display ads, which are used extensively in advertising tobacco products. The nature of youth makes teenagers more sensitive than other age groups to advertising parables and promotion appeal. Many brand loyalties, according to Raphael, started in adolescence and surviving into adulthood[13]. Research from Beltramini on cigarette warnings shows that adolescents are less trustworthy[14]. According to Maluoff et al, it requires a high level of reading comprehension[15]. Teenagers tend to underestimate the risk of using dangerous products. Laventhal et al, research proves that adolescents tend to underestimate the dangers of smoking and overestimate smoking excess[16]. Teenagers see themselves as immune to the negative effects of smoking, according to Fischer et al,young people also have difficulty connecting the negative impacts that can occur in the future[17]. General provisions of Gov. Reg. No.19 of 2003 concerning Amendments to Gov. Reg. No. 81 of 1999 concerning Safeguarding Cigarettes for Health require cigarette labels, i.e. any information about cigarettes in the form of pictures, writing, a combination of both, or other forms included in cigarettes, put in, placed on, or are part of cigarette packaging.

Regarding advertising about products that are detrimental to public health, the government can limit or even ban[18]. In the United States, Fox et al,who quoted Teinowitzeven though no central regulations were applied to tobacco product advertising, the local government began to take action[7,8]. Tobacco advertising is prohibited on billboards in the Baltimore are. Baltimore regional regulations forbidding the placement of any signs from cigarette advertisements in publicly visible locations, such as billboards, building sides, and free standing signage[2].

In 1965 the cigarette warning was adopted in the United States. Cigarette warnings are one of the most widespread uses of explanation disclosure ordered by central policy and help the role of government policy in warning consumers of the dangers of smoking[7]. Warn adolescents can prove difficult. The nature of adolescence makes dependence on tobacco, making stopping smoking a very difficult thing to do later. Warning of statistics and the increasing amount of evidence of increased smoking rates in adolescents, President Clinton proposed steps to reduce smoking rates in adolescents. One such step is to further limit advertising. On August 10, 1995, President Clinton, as Press issued by the White House 1995 page 1, announced a six-step plan to limit "advertisement, promotion, distribution and marketing of cigarettes for teenagers." First, teens must prove their age with an identity card to buy cigarettes. Second, automatic sales machines will be banned. Third, smokeless cigarette or tobacco billboards near playgrounds or schools will be banned. Fourth, pictures will not appear on billboards outside the room or in advertisements noticed by many teenage audiences. Fifth, marketing to teenagers is prohibited, and the prohibition includes items ranging from selling single cigarettes, T-shirts and sports bags to sponsoring sports activities. Sixth, through education efforts, the tobacco industry must fund and implement an annual $ 150 million campaign aimed at stopping teenagers from smoking[2].

If we see in the United States there is an institution called the Federal Trade Commission (FTC) which has been involved in the continuous supervision and marketing practice of cigarette advertising, starting in the early 1940s. Cigarette advertising in the United States is more limited than other legitimate consumer products. Some regulations are mainly information (warning labels), while others affect the level of direct advertising (broadcast ban). Over a period of six decades, the FTC governed the overall direction of cigarette

marketing, including content advertising and placement, label warnings, and product development. Through the testing program, he is able to influence the types of cigarettes produced and consumed. The FTC is involved in monitoring the practice of cigarette advertisements and preparing in-depth reports on these practices. It was held with opinions on cigarette testing, advertising, and labeling, and published consumer smoking advisories. Directly or indirectly, the FTC has begun or influenced the promotion and development of products in the cigarette industry[19]. The Federal Trade Commission (FTC) has the power to regulate "dishonest and deceptive business practices," including advertisements for food and drugs. With the section on the 1967 State Law on Cigarette Labels and Ads Congress has authorized the FTC to enforce restrictions on cigarette advertising and report to Congress once a year in relation to smokeless tobacco and tobacco advertising, including recommendations for further restrictions by the agency believed to be enacted by Congress[2].

Conclusion

In Indonesia, cigarette advertising is limited by several requirements, but cigarette advertising is actually more liberal and unethical. Some cigarette advertisements are illogical and misleading. Advertisers use psychological persuasion, which advertisers are aiming for is not the use of reason by users or potential users but human emotions. Manipulative cigarette advertisements create desires in consumers who are psychological. Many cigarette advertisements do not meet the conditions. Violations at the time of display of cigarette advertisements on electronic media also on the prohibition to display advertisements for the appearance of cigarettes and or the use of cigarettes.

Cigarette ads target the share of teenagers and children. Cigarette advertisements encourage young people to start smoking which harms children and adolescents. Advertising plays a role in the initial use of tobacco products. Cigarette advertisements harm teenagers and children. To reduce smoking rates in teenagers, it is necessary to limit cigarette advertising. The beginning of the use of tobacco products by teenagers needs to be prevented. Cigarette marketing, including advertising to adolescents besides being prohibited, education efforts need to be made that the tobacco industry must fund and implement campaigns aimed at stopping youth from smoking.

Suggestion: Limiting cigarette advertisements for teenagers in addition to promotion, distribution and marketing. Reducing smoking rates in teenagers. Institutions that regulate, supervise and sanction the overall direction of cigarette marketing, including advertisements, are needed. Censored before airing on television and mass media as well as continuous monitoring of cigarette advertising practices. Local regulations should prohibit the placement of any sign of cigarette advertisements in a publicly visible location and monitor the content of advertisements on billboard advertisements.

Term Lowbirth Weight Neonate: Maternal Factors

Bashar Mukhlif Khalaf[1], Zuhair Idreas Mohammed[1], Nada Hasan Ali[1]

[1]Board Dr. Pediatrics, Department of Pediatrics, Al-qayarh General hospital, Mosul, Iraq

Abstract

The current research aims to detect the maternal risk factors that influence the birth weight of the babies. Risk factors related to the mothers like gestational age, maternal age, nutrition, and medical problems play a role in the delivery of infants with low birth weight. The sample consisted of 267 ladies give a birth to newborns. Mothers with less than or = 150cm giving low birth weight babies (62.3%) while those with more than 150cm giving low birth weight babies (37.7%) . In the normal birth weight group, working mothers represent (82.1%) while in normal birth weight group they represent (17.4%). Mothers more than or = 35 years old giving (33.1%) normal birth weight babies. Young mothers less than 20 years old gave more low birth weight babies (28.7%) than older mothers with more 20 years old.

The maternal risk factors of low birth weight babies include maternal age < 20 years old, low maternal educational level, working mothers, smoking, pre-pregnancy weight<50kg, maternal height ≤150cm, low socioeconomic status, inter pregnancy interval of less than one year, previous low birth weight babies, history of infertility and first week neonatal death, low rate of visiting to antenatal care centers.

Keywords: *Low birth weight, risk factors, antenatal care, fetal growth.*

Introduction

According to the WHO, low birth weight (LBW) is defined as the weight at birth of less than 2.5 kg whatever the gestational age [1].While, very LBW (VLBW) is the infant weight < 1.5 kg, and extremely LBW (ELBW), the infant <1kg.[2].

LBW is considered a major health concern all over the world, particularly in developing countries. Around 25 million LBW infants are born per year, and 20 % of them die globally[1].

Infants who weigh less than 2,499 gm at birth are at twenty times more risk of neonatal death than those who weigh more than 2,500 gm[3].

Corresponding Author:

Pediatrician Dr., Department of Pediatrics, Al-qayarh General hospital, Mosul, Iraq
e-mail: basharmukhlif@gmail.com

The prevalence of low birth weight in in developed regions (7%) while in developing countries (16.5%) [4].

There are many risk factors of LBW in developing countries include the age of the mother, maternal education, attendance of the antenatal care (ANC) follow-up, socioeconomic status, and maternal body mass index[5].

In general, LBW is due to genetic, nutritional, obstetric, constitutional, prenatal maternal morbidities, drugs and toxins exposure, and ANC follow-up. In addition, other risk factors have also been reported like age of the mother, smoking, birth spacing, genital infections, anemia, stress, and ill health mothers 6.

The aim of the study was to find the maternal risk factors for LBW in full term babies.

Materials and Method

This is a prospective cohort study that was carried out during the period from the 1st of March 2019 till the 1st of July 2019 that involving 267 ladies delivered at AL-Khansaa and Ibn-Alatheer Maternity and Children Teaching Hospitals in Mosulcity/Iraq.

Data were collected through a special questionnaire regarding mothers age, address, education, smoking habit, history of abortion or infertility, residency (rural or urban), antenatal care visit with the number of these visits, any supplementation of tonics, any ante-partumcomplication have been evaluated and the informed consent was taken from every mother. Newborn babies were examine for gender and presence of congenital anomalies. Gestational age was determined were the full term babies (³37 weeks of gestation)and the birth weight was measured immediately after delivery.

The newborns divided into two groups, a case group with LBW <2.5 kg and a control group with normal birth weight (NBW) of ≥2.5 kg.

- **Inclusion Criteria:** All live babies born at term-gestational age.
- **Exclusion Criteria:** Intra-uterine deaths, still-births, and twins deliveries.

The results were analyzed using Chi-squared method, where P-Value is not significant if it is > 0.05, significant if < 0.05, and highly significant if < 0.001.

Results

Out of 267 term babies, there are 166 (62.5%) with normal birth weight, and 101 (37.5%) with LBW.

Table (1) shows that a mothers where maternal age < 20 years, low maternal educational level, working mothers, smoking habit, low socioeconomic status associated with significant relation with LBW.

	Total	**101**	**37.8**	**166**	**62.2**	

*After exclusion of primiparous (114) from total number (267), the remain number (153).

As shown in **table (3)**, mothers who had delivered LBW babies previously, (68.3%) gave birth to LBW babies again. The risk of giving birth to LBW babies significantly increased in mothers with history of still birth (77.1%), previous history of first week neonatal death (57.4%) and history of infertility (61.4%).

Table (4) Distribution of the birth weight according to the mother attendance to antenatal care centers

ANC attendance		LBW		NBW		p-value
		No.	%	No.	%	
1	**Antenatal care**					
	Absent	26	25.8	24	14.5	≤0.001
	Present	75	74.2	142	85.5	
	Total	**101**	**37.8**	**166**	**62.2**	
2	**Number of visits**					
	1-3	35	46.7	11	7.7	<0.001
	4-6	21	28.0	51	35.7	
	≥ 7	19	25.3	81	56.6	
	Total	**75**	**31.9**	**143**	**68.1**	

ANC attendance		LBW		NBW		p-value
		No.	%	No.	%	
3	**Date of 1st visit**					<0.005
	1st trimester	15	20.0	59	41.3	
	2nd trimester	26	34.7	44	30.8	
	3rd trimester	34	45.3	40	27.9	
	Total	**75**	**31.9**	**143**	**68.1**	
4	Iron-folate supplementation					<0.005
	No	58	77.3	58	40.6	
	Yes	17	22.7	85	59.4	
	Total	**75**	**31.9**	**143**	**68.1**	

As shown in **table (4)**. Significant association was found between the number of visits to ANC center and giving LBW-babies. The mothers who was not received iron-folate supplementation were significantly at higher risk of giving LBW babies.

Discussion

In this study a significant association was observed between the age and fetal growth were mothers less than 20 years old gave birth to a LBW babies. Similar finding was observed by Althabe et al study[7]. This could be explained by the fact that such teenagers have not completed their physical growth and the additional caloric requirement of the pregnancy may create a competition between the mother and the fetus for nutrients.

human health may be effected by environmental exposures but no significant association was found between residence and fetal growth. This is in agreement with the study of Domple[8].

The present study showed that as the maternal educational level increases, the chance of delivering LBW neonate decreases, the same result was reported in Pakistan[9].

working mothers were more prone to deliver LBW neonates, this is partially may explained by the lack of the time needed for mother to rest and that exercise during work may reduce blood flow from the uterus to the placenta. This result coincides with study carried out in Tehran which illustrate that LBW among employed mothers was 5 times more likely than unemployed ones[10].

In our study, there is a significant association between cigarette smoking and delivering LBW neonate. This finding was consistent with the finding reported byZheng et al [11].

Maternal pre-pregnancy weight status has an important rule on fetal growth and the ability of the placenta to supply essential nutrients to the fetus depends on the nutritional status of the mother[12]. This study show that women with low pre-pregnancy weight (<50 k.g) were more prone to deliver small babies. the same result was reported byZ. He et al [13].

Maternal height also revealed significant association with LBW babies, women whose height were less than or = 150cm appeared to be significantly at higher risk of having LBW-babies. This might be explained by genetic susceptibility. This result was in accordance with the finding in study in 2015 in Nepal[14].

The LBW babies were more likely to be the first born baby. This might be explained by the fact that multiparous women know more about how to deal with their pregnancy. This finding was similar to that found byRosy et al[15].

Result demonstrated that those mothers with low SES were more prone to delivering LBW neonate when compared with high SES mothers. The logic explanation for this finding is that mothers with low SES may not attended health care and with poor nutrition. This result supports that reported by Rosy et al[15].

This study showed that there was a significant association between short spacing and LBW babies. This might be due to nutritional deprivation and incomplete

return of the maternal physiology to normal levels encountered among rapid conceivers. similar finding were reported by other studies in India[16].

Mother with history of previous LBW delivery are more likely to having LBW neonates in subsequent pregnancy. This finding was also obtained byMvunta et al[17]. The explanation of this finding may be due to the persistence of socio-demographic factors like age, poor nutritional and social status.

The study also clarified a significant risk of LBW in pregnancy preceded by history of stillbirth or first week neonatal death. This finding was compatible to that found by Feresu[18].

Compared with infants conceived within 12 months of trying, those conceived after a waiting time of 12 months have a higher risk of preterm birth and LBW[19]. Mothers with history of infertility were more prone to deliver LBW-babies. This finding was in agreement with the study of Wannous et al in Syria[20].

Regarding previous history of abortion, no significant association was found with LBW babies, this finding support the finding detected in Syria[20].

Prenatal care considered an important tools available to detect obstetric risk factors that may impact on optimal fetal development, and final birth weight[21] Mothers with no antenatal care, were more prone to deliver LBW babies this was in agreement with that found by Howlader[22].

The prevalence of LBW significantly affected by micronutrient deficiencies during pregnancy, particularly iron and folate[23]. This study detected that nutritional supplementation with iron and folate during pregnancy was associated with reducing the risk of giving LBW neonate. This finding was in agreement with that observed by Howlader[22].

Conclusion

The study showed the maternal risk factors for LBW neonates were maternal age 20 years, low maternal educational level, working mothers, smoking habit, pre-delivery weight (less than 50 kg), maternal height (≤150cm), low socioeconomic status and short-spacing (1 year), less frequent and late visits to ANC-centers and with no supplementation of iron and folate. Previous bad obstetrical history is a probable risk factor.

Detection of Heavy Elements and Pathogenic Microorganisms in the Water and Sediments of Domestic Water Tanks in the Center of AL-Nasiriyah

Basim Y. Al-khafaji[1], Hassan Abd Ali Namaa[2]

[1]Prof., [2]MBS., Thi-Qar University-Colloge of Science Thi-Qar University-Colloge of Science

Abstract

The current study was conducted to show the presence of heavy elements and pathogenic microorganisms and the quality and validity of water and sediments in the household water tanks at the city center of Nasiriyah and their suitability for household and drinking uses from the autumn 2019 to summer 2020. Physical, chemical and biological checks of water were carried out in three stations, two selected stations located in the center of Nasiriyah city (1- Erido 2- Al-Salhiya), and the third station, Al-Asalah, which is located in Al-Shatrah district. Samples were collected monthly and quarterly, with three replications per station. The study included measuring the temperature of air and water, the pH, salinity, turbidity, dissolved oxygen DO, and the Biological Oxygen Demand BOD5. In addition, the concentration of four heavy elements (cadmium, copper, lead and zinc) in the water was measured in its entirety. The study included measuring the TOC content and mixing the sediment, and also the concentration of four heavy elements (cadmium, Copper, lead and zinc) are completely sediment. The study also included investigation of bacterial contamination by detecting the total numbers of aerobic bacteria, the number of coliform bacteria, the number of fecal coliform bacteria, the numbers of fecal and Pseudomonas Aeruginosa bacteria in the water and sediments. The results of the physical and chemical tests of water in the study stations showed that the values of air and water temperatures ranged between (20.1-40) C and (17.50-30) C, respectively, and that the water of the studied stations was basic as the pH values ranged between (7.00-8.20) The salinity values ranged between (485-837) ppm, and the turbidity values were between (2.50-6.79) NTU. The dissolved oxygen values ranged between (5.39-8.01) mg/liter, and the Biological Oxygen Demand BOD5 were between (2.93-8.5) mg/liter.

Keywords: *Heavy elements, pathogenic, microorganisms, sediments, domestic water, tanks, AL-Nasiriyah*

Introduction

Water is one of the main and basic pillars of life, and the presence of water is necessary for the existence of life, so water pollution is one of the basic and main risks that threaten the lives of all living things, especially human life. Therefore, the water must be free from the chemical, physical and biological contaminants of drinking water, and this water must be acceptable for being colorless, tasteless and odorless[(1)]. Attention has been paid by the World Health Organization, the US Environmental Protection Agency and many other health institutions to diseases that could result from water pollution and to control or prevent those diseases.[(2)]

Literature Review: Measuring the concentrations of heavy elements in the water cannot give a reliable and accurate indication of the degree of pollution due to the difference in the quantities of water discharges, the suspended load and the imbalance of the sources that throw these pollutants into the water environment. Therefore, its concentration in sediments was measured because it is the main and accurate indicator of contamination with these types of pollutants, and it is the

e-mail: hsnalamry315@gmail.com

direct recipient of pollutants in the aquatic environment [3] and represents an important source of heavy elements in the aqueous phase as the role of sediments is a store and transporter of heavy elements, and through the sediments we can identify the history of pollution, due to their ability to pollute and collect heavy elements significantly. It is possible that the concentration of these elements in sediments is more than (1000-10000) times than their concentration in water.[4]

Methodology

The following were performed to 3 water samples: air and water temperatures, volumetric analysis of sediment particles, extraction of heavy elements from water, extraction of heavy metals from sediments, the culture media and isolation.[5]

Results

- **Air and Water Temperature:** It was found that there are no significant differences. Among the stations, as no significant differences were found, as for the seasons, significant differences were recorded for all seasons. The temperatures showed a clear seasonal change during the study period, as the lowest values were during the winter season and the highest during the summer, and this can be explained by the nature of the climate in Iraq.[6]
- **The pH Values:** Results of the statistical analysis showed that there were no significant differences between the stations. This narrow range of values may be attributed to the pH in the stations during the seasons of the year refers to the amount of industrial water that is discharged and its dissolved salts that are directly proportional to the pH value and thus be basic[7].
- **Turbidity:** Results of the statistical analysis showed that there were no significant differences between the stations. The suspended matter that causes turbidity is organic and includes phytoplankton, animal and microscopic organisms, or inorganic materials such as soil, clay and silt particles, and turbidity is responsible for water color changes[8].
- **Dissolved Oxygen (DO):** Results of the statistical analysis showed that there are no significant differences between the stations, but in the seasons, there are significant differences for all seasons. The highest value was recorded in the third station during the summer of 2020 and the reason for this increase may be attributed to the fast water currents, good ventilation and the continuous mixing of water[9].
- **Biological Oxygen Demand (BOD5):** It was noticed that there were no significant differences, but in the seasons, there are significant differences for all seasons. From the results, the highest BOD5 values were observed in the third station, which is due to the arrival of organic wastes that were discarded in the river water or human and industrial activities near the first station. This may be due to rainfall and high water levels, and this result is identical to what Naji (1988) stated, and they agreed with him[10].

- **Sediment Total Organic Carbon Content (TOC %):** The statistical analysis revealed that there are significant differences between the stations. Human activities and natural processes lead to an increase in the carbon concentration of total organic matter in the sediments. Likewise, organic carbon in sediments increases with small grain size (silt) and has great affinity for new crystalline deposits[11].

Table (2): TOC% rates for study stations for the period from Fall 2019 until Summer 2020

TOC	Autumn		Winter		Spring		Summer	
	M	SD	M	SD	M	SD	M	SD
St1	2.41b	.44	2.18b	.09	3.56a	.12	4.12a	.16
St2	3.24a	.85	3.61a	1.26	3.50a	.48	3.86b	.05

- **Volumetric Analysis of Sediment Particles:** The statistical analysis showed statistically significant differences of sediment mixture between the stations. The results showed that the sediment mixture was Clay-silty in all the stations studied. The percentage of soil plays an important role in determining the quality of the sediment, as it affects the ability of the sediment to retain the ions of heavy elements, organic matter and salts in quantitatively and qualitatively[12], the more small-diameter granules are, the more quantities are preserved.

Table (3) showed mixing rates of sediments%

		St.1	St.2
Autumn	Sand	10.3	17.5
	Clay	48	50
	Silt	41.7	32.5
Winter	Sand	5.1	6.2
	Clay	54.8	55.1
	Silt	40.1	38.7
Spring	Sand	1.7	2.4
	Clay	50.1	56.7
	Silt	48.2	40.9
Summer	Sand	18.1	22.4
	Clay	40.9	50.4
	Silt	41	27.2

- **Heavy Elements in Water:** The results of the current study showed that the average levels of concentrations of heavy elements in the water for the three study stations of cadmium, copper, lead and zinc (5.32, 0.46, 0.00432, 0.0052) mg/liter, respectively, as an input of heavy elements in the aquatic environment changes over time, and the main factor that effects on this change in element concentrations is the receipt of water for untreated household, agricultural and industrial wastes, and the highest concentrations of elements were recorded in the summer and the lowest in the fall. This may be due to differences in water levels between seasons, as high water leads to dilution and dispersion of elements, and that the change in the level of water level It contains two-fold concentrations of heavy elements, for example, high water levels reduce the concentrations of heavy elements in the water, and their decrease leads to an increase in the concentrations of these elements[13].

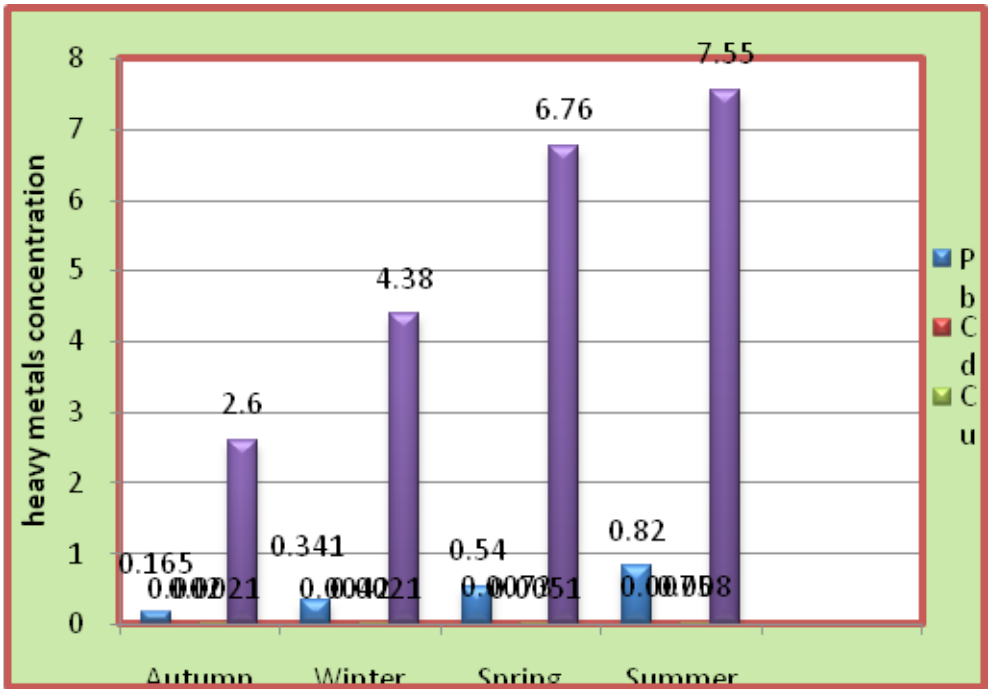

Figure (1) Shows the annual rate of heavy elements in water

- **Total Number of Aerobic Bacteria (TBC):** The results of the statistical analysis recorded the presence of significant differences between the stations. This group represented mostly the bacteria that enter the water from sewage waste and the types of bacteria that wash with the soil into water bodies during the rainy and flood seasons, in addition to the original bacteria present in the water and the types of pathogenic bacteria, including optional aerobic and anaerobic bacteria[14].
- **Total Coliform Bacteria Count (TC):** The results of the statistical analysis recorded the presence of significant differences between the stations. Coliform bacteria are usually found in the intestines of human and warm-blooded animals and are associated with pathogenic bacteria, which is an appropriate microbial indicator to determine the quality of drinking water due to its ease of detection and calculation[15].
- **Number of Fecal Coliform Bacteria (FC):** Statistically, significant differences were recorded between stations except for the second and third stations. No significant difference was recorded between them. Bacteria E. coli is a fecal source due to its permanent presence in human feces and other mammals and birds in large numbers and is rarely found in soil or water not contaminated with fecal waste[16].
- **Counts of Fecal Coliform Bacteria (FSb):** Statistically, a significant difference was recorded

between the stations, as no significant difference was recorded between the second and third stations. The current study recorded the highest rates of fecal coliform bacteria in the first station during the summer of 2020, and this may be due to the previously mentioned reasons about the rates of coliform bacteria and the plant itself. Seasonal changes also play a role in increasing the numbers of this bacterium[17].

Appraisal the Quality of Drinking Tap Water in Different Regions of Kirkuk City

Batool Kh. Mohammad[1], Kameran Sh. Husien[2], Israa Zainal[1]

[1]Assistant Lecturer. College of Science, Kirkuk University-Kirkuk, Iraq,
[2]Professor, College of Science, Kirkuk University-Kirkuk, Iraq

Abstract

This study was conducted to demonstrate the suitability of drinking tap water from different regions of Kirkuk city byanalyzing some chemical and physical properties included (temperature, pH, turbidity, electric conductivity, total soluble solids, total hardness, total suspended solids, nitrates, calcium, magnesium, chloride, sulfate, sodium and phosphate) and eight heavy metals concentration including (Cd, Cr, Cu, Fe, Zn, Ni, Mn and Mg) which have been detected in drinking water. The drinking tap water of Kirkuk city processed by the Directorate of Kirkuk's water for human consumption, all data compared with (IQS 417/2001) except for temperature. The results offered that the concentrations of 8 studied metals are little than National Standards Organization of Iraq (IQS) except for (Ni) which is found to be high (12.267mg/L) dose which not meet specifications, the results were analyzed using the analytic Jena AAS NOVAA 350. The results of chemical and physical properties compared with drinking water standards displays that the concentration of studied chemical and physical are little than the estimated levels that were announced by the National Standards Organization of Iraq(IQS) except for two analysis(turbidity and total soluble solids) were found to be highest rate(6.9NTU) and (79mg/L) respectively which does not meet specifications.

Keywords: *Heavy metals, drinking tap water, water quality.*

Introduction

Water pollution is one of the most important challenges. It has been proven that half of the world's rivers were severely polluted with decrease in the level of water. Water pollution include two sources: (point and non-point) source.[1] Point sources are effectively identifiable sources, including: oil effuse from a tanker, igniter from a factory, wastewater streaming (both municipal and manufacturing) and storm sewer discharges and affect mostly the area near it, while, non-point sources are those of different sources of origin and the number of ways in which pollution has occurred in groundwater or surface water and in the area near it like runoff from agricultural fields, urban waste…etc. Sometimes environmental pollution in one place has an influence hundred or even thousands of miles away, which is known as trans-border pollution.[2] Water pollutants may be organic pollutants (comprise of insecticides and herbicides, organo -halides and other forms of chemicals; bacteria from sewage and lives tocks farming; food processing wastes; pathogens; volatile organic compounds … etc.) and inorganic pollutants (may emerge from heavy metals which arise from acid mine drainage; silt from surface run-off, logging, slash and burning practices and land filling; fertilizers from agricultural run-off which include nitrates and phosphates... etc. and chemical waste from industrial manufacturing effluents).[1] Heavy metals are known as metallic elements that have a comparatively high density and specific gravity (about five times) compared to water,[3,4] they exist on the earth with different ratios in rocks and soil depending on their location. They are released from rocks by weathering processes to form soil

Corresponding Author:
Kameran Sh. Husien
Professor, College of Science, Kirkuk University-Kirkuk, Iraq
e-mail: kamerandalo@uokirkuk.edu.iq

and are bio-geochemically cycled to form rocks again in a natural cycle. Inorganic heavy metals as pollutants cannot degrade like organic pollutants and turn to harmless products but continue and accumulate in the soil.[5,6] Naturally water contain different concentrations from heavy metals,[7, 8] some of them are essential for the aquatic life, and others are toxic. Accumulation and distribution of metals in the aquatic system dependent on the sediment texture, mineralogical composition and physical transport.[9] Heavy metals sources in water may be from waste water without treatment, industries effluents and contamination with heavy metals ions.[10] Surface water is much exposable to contamination by heavy metals due to untreated sewage and factory waste into rivers and lakes.[11] The importance of heavy metals is getting more for their accumulation through tropic level and non-degradable nature causing a deleterious biological effect.[12, 13] The deadlier diseases like edema of eyelids, tumor, congestion of nasal mucous membranes and pharynx, stuffiness of the head and gastrointestinal, muscular, reproductive, neurological and genetic distortions caused by some of these heavy metals have been documented.[14] Subsequently, monitoring heavy metals is important for safety assessment of the environment and human health in particular.[12, 15]Also, to evaluate the status of the river water quality with respect to drinking and agricultural irrigation purposes.[16]Heavy metals are absorbed through the orally, inhalation and/or skin. Regardless of the manner of heavy metal entry in the body, the blood circulatory system is possibly the first to be affected following exposure and adverse effects on blood coagulation can lead to associated thrombotic disease.[17] The aim of this study is to evaluate the quality of water, with respect to its heavy metal contamination index method for drinking tap water quality in different regions of Kirkuk city.

Materials and Method

The Studied Regions: Kirkuk city located in the north part of Iraq, between ((44° 15′00″ -44° 30′00″E) and (35°19′00″-35° 32′00″ N)[18] (figure 1).

Khassa is Crisp River flux from north - east to south-west across the central of Kirkuk city. The study region is characterized by arid to semi-arid climate. And the main river that requires the major water source to Kirkuk governorate is Lasser Zab. The length of Lesser river is 400 km, and its catchment area is about 22,250 km2.19 Generally, this region consists of industrial, domestic, agricultural and oil fields site. Oil is the major source of its economic efficacies.

Kirkuk City (1) Gharnata. (2) Quria. (3) Hazir. (4) Shorja . (5) Shurau. (6) Raheem Awa. (7) Arafa. (8) Khadraa. (9) Wasty.

Figure 1. Map of Iraq showing the sample region in Kirkuk city.

Samples Collection: The samples of drinking tap water were collected by following the quality sample assortment protocol and tips given inCentral Organization for Quality Control and Standardization, Council of Ministers, Republic of Iraq (IQS 417/2001) results,[20] in November 2019 from regions which is next: Gharnats, Quria, Haziran, Shorja, Shurau, Raheem Awa, Arafa, Khadraa and wasty. Drinking water sample were collected in 1 liter capacity plastic bottles. Before sampling, the special precautions were taken throughout the sampling of water within the elite places of study regions. Before the gathering of the samples, the bottles were washed with cleaner directed by tap water and different times rinse with distilled water. The water at the sample locations were allowed to rinse for several time then the bottles were rinse thrice with this water and 1 liter was taken as sample from each source of water. The samples were preserved at 4°C until used.

Sample preparation and experimental analysis

Samples were prepared by following two steps: [1] The first step including determination of physico-chemical properties (pH, electrical Conductivity (E.C°), temperature (C°) and total dissolved solid (T.D.S)) for drinking tap water. The pH of the drinking tap water samples was measured using a pH meter, which calibrated, with two standard solutions (pH 4.0 and 7.0). The conductivity, temperature and total dissolved solid of the samples was measured using a conductivity meter. The probe was calibrated using a standard solution with a known conductivity. [2] The second step including the laboratory performed which include: The analyses of eight heavy metals including (Cu, Zn, Mg, Fe, Cd, Mn, Cr and Ni) using Flame atomic absorption spectrophotometer (AA-6800 AAS coupled with GFA-EX7 graphite furnace atomizer and ASC-6100 auto sampler from Shimadzu (Koyoto, Japan), for samples. The standard solution for each tested element was prepared according to its concentration and used to calibrate the system before analyzing each water sample. The device automatically recorded focus and results of statistical analysis in Standard Deviation (SD) and Relative Standard Deviation (RSD).

Concentrations of elements were estimated using the analytic jena AAS NOVAA 350, which uses acetylene gas as fuel for both Cd, Mg, Mn, Fe, Cu, Ni, Zn, Cr respectively, and used air as a Catalyst for all elements. The Liquid spray rate 4ml/min at wavelengths was 228.8, 285.2, 279.5, 248.3, 324.8, 232, 213.9, 357.9 (nm) respectively. Also, Standard analytical chemistry method and EDTA were used to measure the Ca and total hardness, Argentometric method is used to measure the Cl and the Mg using calculation method. The phosphate was measured Vanadomolybdo phosphoric acid colorimetric method, Flam emission Photometer is used to measure the Sodium and the sulfute using Gravimetric method. For the turbidity used turbidity meter. Measurement of the TSS by gravimetric method. Finally, using Brucine method to measure nitrate.

Results and Discussion

Table (1) shows the values of the analyzed physiochemical parameters of drinking tap water from different regions in Kirkuk city.

Table (1): Physiochemical parameters of drinking tap water from different regions in Kirkuk city

Region	pH	T (C°)	EC° (µs/cm)	*TDS (mg/l)	Turbidity (NTU)	**TSS (mg/l)
Gharnata	8	20.9	388	179	5.9	69.3
Quria	7.8	20.6	386	177	6.4	73.7
Haziran	7.9	19.9	410	185	6.9	79
Shorja	7.9	20.2	386	175	6.1	71.3
Shurau	8	21.5	556	259.3	4.4	54
Raheem Awa	7.9	20.4	411	188	5.6	68.7
Arafa	7.7	24.2	397	195.3	4.8	58
Khadraa	8.1	20.6	410	188	6.5	68.3
Wasty	8	20.2	407	181.3	5.8	75

*TDS :total Dissolved solids, ** TSS :total Suspended Solids.

The obtained pH values ranged from 7.7 to 8.1 with an overall mean of (7.9), the permissible limit of pH is given as (6.5-8.5) by IQS/417. The highest value found in Khadraa region and the lowest in Arafa region of Kirkuk city, note that it conform to the specification, indicating that the during tap water in Kirkuk city is alkaline (pH >7). Furthermore, there are no remarkable variations in sampling sites, and thus, it can be concluded that the water treatment and purification method had only a small effect on the hydronium ion concentration.[21] The temperature results indicated that the highest temperature of drinking tap water were found in the Arafa region while the lowest in the Haziran region, the temperature ranges between (19.9 - 24.2C^{o}) with an overall mean of (20.9C^{o}), the water temperature changes with the change in weather. Measurement is necessary because it affects various water properties such as (viscosity, density, solubility) of chemicals and bacteriological activity. The temperature affects chlorine effectiveness in water sterilization where chlorine is more effective in sanitizing water with increasing water temperature,[22] as cleared in the table (1). The E.C^{o} of the regions to drinking tap water of Kirkuk city was measured and found that the highest value in Shurau region while the lowest value in Shorja and Quria regions, where the E.C^{o} ranged between (386 – 556) µs/cm with an overall mean of (416) µs/cm as presents in table (1), the permissible limit of E.C^{o} is given as 1000 µg/cm by IQS/417, note that it conform to the specifications. There is a relationship between turbidity and water quality, also a between turbidity and bacterial content in water, the turbidity lower the chlorine's effectiveness in sanitizing the water and therefore water need more chlorine to eliminate the bacteria and pathogens.[23] The analysis showed that the rang value of turbidity within the range of (4.4-6.9) NTU with an overall mean of (5.65) NTU as in presents table (1), the regions of drinking tap water Kirkuk city results found that the highest value in Haziran region and the lowest value in Shurau region. the permissible limit of turbidity is given as 5 NTU by IQS/417 and found that it does not comply with the specifications. The T.S.S consists of organic and clay materials, and contains some microorganisms such as algae and bacteria. In the current study the values of T.S.S ranged from (54 to 79) mg/L and TSS an overall mean of (68) mg/L of the regions to drinking tap water of Kirkuk city and found the highest value in Haziran region and the lowest value in Shurau region as cleared in table (1). The permissible limit of T.S.S is given as 0mg/L by IQS/417, and it does not comply with the specifications. The T.D.S of the regions to drinking tap water of Kirkuk city was measured and found that the highest value in Shurau region while the lowest value in Shorja and Quria regions, where the T.D.S ranged between (175 – 259.3) mg/L with an overall mean of (191) mg/L as presents in table (1).

Table (2): Chemical analysis of drinking water in the city of Kirkuk:

Region	Po_4^{-3} (mg/l)	Total Hardness (mg/l)	Ca^{+2} (mg/l)	Mg^{+2} (mg/l)	Cl^{-} (mg/l)	Na^{+} (mg/l)	So^{-2}_4 (mg/l)	NO_3^{-} (mg/l)
Granda	1.98	178	37.3	21.3	16.7	9.3	38	7.076
Quria	2.383	182	38.7	20.8	16.7	9.33	38.1	7.64
Haziran	1.7	182	38	21.13	16.6	9.5	36.7	7.25
Shorja	1.45	182	38.7	20.9	16	9.3	36	7.125
Shurau	1.323	195	47.3	18.63	23.3	14.7	46	7.162
Raheem Awa	1.625	178	36	21.5	13.3	9.3	33.3	7.458
Arafa	1.348	182	38.7	20.8	16	9.7	35.3	7.69
Khadraa	1.953	183.7	37.7	21.83	17.3	10.7	34	7.209
Wasty	1.653	185	38.7	21.6	17.3	10.3	34	6.758

The PO_4^{-3} of drinking tap water regions of Kirkuk city, found to be higher value in Quria region and lower rate in Shurau region, where the PO_4^{-}ranges between (1.323 – 2.383) mg/L with an overall mean of (1.7) mg/L as in table (2). The permissible limit of PO_4^{-3} is given as 3 mg/L by IQS/417, it conform to the specifications. The total hardness and Ca^{+2} of the above regions drinking tap water of Kirkuk city was measured and found that the

highest value in Shurau region and the lowest value in Raheem Awa region, where the total hardness is between (178 – 195) mg/L with an overall mean of (183) mg/L, Ca^{+2} is ranges between (36 – 47.3) mg/L with an overall mean of (39) mg/L as clear in table (2), the permissible limit of total hardness is given as 500 mg/L and Ca^{+2} is concentration equal to 50mg/L by IQS/417 and it conform to the specifications. The measuring Mg^{+2} of drinking tap water in different regions of Kirkuk city cleared that higher value in Khadeaa region and the lower value in Shurau. The Mg^{+2} ranges between (18.63 –21.83) mg/L with an overall mean of (20.94) mg/L as in table (2), the permissible limit of Mg^{+2} is given as 50 mg/L by IQS/417, note that it conform to the specifications. Measuring the Na^{+} and Cl^{-} concentration of the drinking tap water of Kirkuk city, the results indicated that the Higher value were in shurau region and the lower value in Raheem Awa region, where the Na^{+} ranges between (9.3 - 14.7) mg/L with an overall mean of (10) mg/L, and Cl^{-} ranges between (13.3 – 23.3) mg/L with an overall mean of (17) mg/L as in table (2), the permissible limit of Na^{+} is 200 mg/L and Cl^{-} as 250mg/L by IQS/417, they conform to the specifications. The SO_4^{-2} concentration of the drinking tap water regions of Kirkuk city found that the higher value in Shurau region and the lower value in Raheem Awa region, where the SO_4^{-2} ranges between (33.3 – 46) mg/L with an overall mean of (37) mg/L as in table (2), the permissible limit of SO_4^{-2} is given as (250) mg/L by IQS/417 and it conform to the specifications . The NO^{3-} concentration was measured of the drinking tap water regions of Kirkuk city and found that the higher value in Quria region and the lower value in Wasty region, where the NO_3^{-} ranges between (6.758 – 7.69) mg/L with an overall mean of (7.2) mg/L as in a table (2), the permissible limit of NO_3^{-} is given as (50) mg/L by IQS/417, it conform to the specifications. The concentration of Cu in the drinking tap water samples ranges from (0 - 0.526) mg/L with the average of (0.2012) mg/L as in a table(3). The permissible limit of Cu is specified as 1 mg/L by IQS/417, it conform to the specifications.[24]

Table (3): The values of (Cu, Ni, Zn) by Flame atomic absorption spectrometer of drinking tap water in different regions of Kirkuk city:

Region	Copper			Nickel			Zinc		
	mg/l	SD	RSD[%]	mg/l	SD	RSD[%]	mg/l	SD	RSD[%]

Arafa	0.08715	0.161935	201.085	3.901	0.583733	14.02333	N.D	N.D	N.D
Khadraa	N.D	N.D	N.D	5.6755	0.9523	14.8515	N.D	N.D	N.D
Wasty	N.D	N.D	N.D	0.9442	0.7812	133.075	N.D	N.D	N.D

The concentration of Ni in the drinking tap water samples ranges from (0.9442– 12.267) mg/L with the average of (6.5759) mg/L as in a table (3). The permissible limit of Ni is given as 0.02 mg/L IQS/417 for drinking tap water, all samples did not meet the permissible limits of IQS/417. The high Ni concentration was sound in samples of Shorja, Huzairan and Quria regions and the lower region in Wasty region.[25] The concentration of Zn of the different regions drinking tap water of Kirkuk city, did not reach the percentage of Kirkuk city regions as in table (3). The permissible limit of Zn is given as 3 mg/L IQS/417 for drinking tap water. Each specimen was within the permissible limits of IQS/417.[26] The concentration of Fe in the drinking tap water samples ranged from (0- 0.0205) mg/L with the average of (0.01907 mg/L) mg/L as in a table (4). The permissible limit of Fe is given as 0.3 mg/L IQS/417 for drinking water. Each the specimens

were within the permissible limits of IQS/417. The high Fe concentrations were noticed in Gharntaa and Quria samples of the study regions but there are not in Wasty, Khadraa, Arafa, Raheem Awa, Shurau and shorja of the study regions.

Table (4): Measurement of (Cd, Mn, Fe) by Flame atomic absorption spectrometer of drinking

Region	Iron			Cadmium			Manganese		
	mg/l	SD	RSD[%]	mg/l	SD	RSD[%]	mg/l	SD	RSD[%]

Khadraa	N.D	N.D	N.D	N.D	N.D	N.D	0.007591	0.0000297	0.390333
Wasty	N.D	N.D	N.D	N.D	N.D	N.D	0.007587	0.0000577	0.767667

The concentration of Mn in the drinking tap water samples ranges from (0.00299- 0.007591) mg/L with the average of (0.005452) mg/L as in a table (4). The permissible limit of Mn is given as 0.1 mg/L IQS/417 for drinking water. Each the specimens were within the permissible limits of IQS/417. The higher Mg concentrations were noticed in samples khadraa and Wasty of the study regions and the lower rate in Gharnata of the study region. The levels of Cdpresent in drinking tap water of Kirkuk city appeared that did not get a percentage in the different regions of Kirkuk city as in a table (4). The permissible limit of Cd is given as 0.003 mg/L IQS/417for drinking tap water. Each the specimens were within the permissible limits of IQS/417. The Cr levels of the drinking tap water regions of Kirkuk city did not get a percentage in the regions of Kirkuk city as in a table (5). The permissible limit of Cr is given as 0.05 mg/L IQS/417 for drinking water. Each the specimens were within the permissible limits of IQS/417.[27]

Table (5): Mg and Cr concentration by Flame atomic absorption spectrometer of drinking tap water of Kirkuk city.

Region	Magnesium			Chromium		
	mg/l	SD	RSD[%]	Mg/l	SD	RSD[%]
Gharnata	0.450333	0.003441	0.770667	N.D	N.D	N.D
Quria	0.380933	0.003969	1.042	N.D	N.D	N.D
Haziran	0.5796	0.003767	0.745333	N.D	N.D	N.D
Shorja	0.450967	0.003913	0.803	N.D	N.D	N.D
Shurau	1.187667	0.016068	1.777	N.D	N.D	N.D
Raheem Awa	0.628867	0.002311	0.392333	N.D	N.D	N.D
Arafa	0.622	0.010647	1.579333	N.D	N.D	N.D
Khadraa	0.635067	0.006713	0.849	N.D	N.D	N.D
Wasty	0.3641	0.001564	0.431333	N.D	N.D	N.D

The level of Mg of the drinking tap water samples ranges from (0.3641- 1.187667) mg/L with the average of (0.5888) mg/L as in a table (5). The permissible limit of Mg is given as 50 mg/L IQS/417 for drinking water. Each the specimens were within the permissible limits of IQS/417. The higher Mn levels were noticed in samples Shurau and Khadraa of the study regions and the lower value in Wasty of the study region. Likewise, Mg, Mg^{+2} was measured in search and these was a large difference between atom-shaped Mg and ion-shaped magnesium, the reason for this relates to some of the interference that has been challenged due to the presence of some element ions that lead to interference with the magnesium ion.[28]

Table (6) cleared the water quality characteristics according to Iraqi specifications, (minimum, maximum and average) concentration of heavy metals, chemical and physical properties of drinking tap water sample of the studied regions.

Table (6): Classifying water quality characteristics of drinking tap water sample of the studied regions.

Parameters	Unit	(IQS 417/2001)	Min	Max	Average
pH	-	6.5-8.5	7.7	8.1	7.9

Conclusions

Twenty-seven samples of drinking water were collected in Kirkuk region. From the samples analysis the following heavy metal, chemical and physical properties (range) were obtained (in mg/L): pH(19.9-24.2), T.D.S(175-259.3), T.S.S(54-79), No_3^{-2} (6.758-7.69), Mg^{+2} (18.63-21.83), Ca^{+2} (36-47.3), So_4^{-2} (33.3-46), Cl^- (13.3-23.3), Na^+ (9.3-14.7), Po_4^{-3} (1.323-2.383), Cd (0), Cu(0.0655-0.5258), Cr(0), Fe(0.01833-0.0205), Zn(0), Ni(0.9442-12.2673), Mn (0.0029-0.0076), Mg (0.3641-1.1876), $E.C^{o}$ (386-556), total hardness (178-195), Turbidity (4.4-6.9NTU) and temperature (19.9-24.2C^{o}). The results showed that the concentrations of 8 studied metals are little than (IQS) except for (Ni) which is found to be high (12.267mg/L) dose which not meet

specifications, the mean concentrations of the metals were observed in the order: Ni>Mg>Cu>Fe>Mn>Zn>Cd>Cr. The results of chemical and physical properties compared with drinking water standards displays that the concentration of studied chemical and physical are little than the estimated levels that were announced by the (IQS) except for two analysis(Turbidity and total soluble solids) were found to be highest rate(6.9NTU) and (79mg/L) respectively which does not meet specifications. But a tap water and equipped by the Directorate of Water Kirkuk has been found to occur large variations between regions in the physical, chemical characteristics and heavy metal despite being processed from the same source was due to the poor quality of networks, processing and leaks in pipelines causing water pollution.

Conflict of Interest: None of the authors have any conflicts of interest to declare.

Source of Funding: The research was performed independently, there is no funding

Ethical Clearance: The project was approved by the local ethical committee in University of Kirkuk.

Strategies Adopted by Women of Rural and Urban Areas for Weight Losspost-Pregnancy

Blessy Mohandass[1], Amanpreet Kaur[2]; Timsy[2]; Nitika Choudhary[3], Shivani Rana[3], Sonaly Robinson[3]

[1]Nursing Tutor, [2]Assistant Professor, [3]B.Sc. Nursing IVth Year Students, Chitkara School of Health Sciences, Chitkara University, Punjab, India

Abstract

Pregnancy is the most important and pleasurable moment in a woman's life when along with the bliss of motherhood, they also tend to gain extra weight. In the field of medicine, health, or physical fitness, weight loss refers to a reduction of the total body mass utilizing various weight loss techniques. Gaining an adequate amount of weight during pregnancy is essential, but it is also crucial that one should lose the extra pounds to decrease the chances of obesity. The study was conducted to assess the strategies used by nursing mothers to reduce their weight after pregnancy residing in rural and urban areas. The study was conducted to find out the strategies adopted by nursing mothers for weight loss. A self-structured checklist having 27 items of common strategies used for weight loss was used to collect data from the participants. The results revealed that nursing mothers residing in the urban area adopted a higher number of weight-loss strategies as compared to nursing mothers residing in the rural area. The findings of the study that the nursing mother residing in the urban area adopted more weight-loss strategies as compared to nursing mothers residing in the rural area. Level of Evidence: Level III, Evidence obtained from well-designed cohort or case-control analytic studies

Keywords: *Diet, Exercise, Gestational Weight gain, Obesity, Postnatal Weight loss, Pregnancy,Weight Loss.*

Introduction

In the field of health, medicine or physical fettle, weight loss means a decrease in total body mass by a mean decrease in fluid, body fat or adipose tissue or lean mass, i.e., bone mineral deposits, muscle tendon, and other connective tissues. Weight loss can occur either inconspicuously because of malnutrition or disease or even because of a conscious effort emends an actual or perceived overweight or obese condition. "Unexplained" weight loss not due to a drop in calorific intake or exercise is called cachexia and may be a symptom of a severe medical condition. It is commonly known as slim intentional weight loss. "Intentional" weight loss is the loss in total body mass due to efforts to improve fitness & health or by slimming to change one's physical appearance. Weight loss in plus size or rotund individuals reduces health risks,[1] increases fitness[2], and can delay the onset of diabetes.[1] Weight loss also happens when the body utilizes more energy in work and metabolism than it absorbs from food or other nutrients. It will then utilize stored reserves of fat or musculature, resulting in gradual weight loss. [3] There is also a known dietary modification called 'balanced percentage diets,' which are low-calorie diets. Nutritionists most commonly recommend these types of diets because of their minimal detrimental effects. Besides limiting the intake of calories, a balanced diet regulates the consumption of macronutrients. Research states that 55% of the total number of allocated daily calories are from carbohydrates, 15% from protein, and 30% from fats with no more than 10% of total fat coming from saturated forms. A recommended 1,200 calorie diet would provide approximately 660 calories from carbohydrates, 180 from proteins, and 360 from fats, for example. Some studies suggest that increased

Corresponding Author:
Blessy Mohandass
Nursing Tutor, Department of Nursing, Chitkara School of Health Sciences, Chitkara University, Punjab, India

protein consumption can help alleviate hunger pangs associated with lower calorie intake by increasing the sensation of safety.[4] Depression, stress, or boredom can also contribute to weight gain [5], and people are advised to seek medical assistance in these cases. A 2010 study found that dieticians who had a full night's sleep lost more than twice as much fat as dieticians with sleep deprivation.[6][7] Although vitamin D supplementation might help, studies have not supported this [8], a majority of dieters regain the lost weight.[9] According to the American Dietary Guidelines, those who and manage a healthy weight do so most successfully by being careful to consume just enough calories to meet their needs and be physically active.[10] Very few studies are conducted in India that explore post-pregnancy weight control by women. The proportion of women holding 5 kg or more after six months of post-partum ranged from 14% to 20 % in various studies.[11] Recent studies suggest that gestation, along with physical activity behavior among females, can be a powerful teachable movement to promote a healthy diet and eating practices. Appropriate physical exercise and a balanced diet for nutrition might help cut extra pounds. Managing obesity can include lifestyle changes, medications, or surgery. The first intervention for obesity is dieting and physical exercise. [12] Diet modifications may produce weight loss over the short term, [13] but maintaining this weight loss is often complicated and many times requires making exercise and lower-calorie diet, a permanent part of an individual's lifestyle [14] [15] The success rates of long-term weight loss maintenance with lifestyle changes are low, ranging from only 2 to 20%.[16] Dietary and lifestyle changes have also been found to be effective in preventing excessive weight gain during pregnancy and improve the outcome for both the mother and the child. The National Institute of Health recommends a total weight loss goal of 5% to 10% of the person's current weight over six months.[17] The present study aims to find the different strategies adopted by nursing mothers of rural-urban areas for weight loss post-pregnancy and delivery.

Materials and Method

A Non-Experimental Comparative Design was used to find out the strategies adopted for weight control by Nursing Mothers residing in rural and urban areas. Using a Non-probability convenient sampling technique, 50 subjects from rural and 50 from an urban area, a total of 100 nursing mothers were selected. Willing nursing mothers, who were breastfeeding, their child from 03 months up to 01 years after delivery, who were available during data collection, were selected. The investigators developed a self-structured tool after the extensive review of the literature on the relevant topic after discussion with experts and research guides. It consisted of two parts; Part A consisted of demographic variables such as age, education, number of children, mode of delivery, height, type of family, employment status and Part B consisted of self-structured checklist to assess the strategies adopted by nursing mothers for weight control was given to the participant to respond to by tick marking the appropriate point. The checklist had three domains, namely; Exercise having 05 items, Dietary modification having 16 items, and Lifestyle modification containing 06 items. The reliability of the Practice Checklist was checked by Inter- method, which was found to be 'r' =0.9. Formal permission obtained from the office of the Municipal Corporation. The participants were assured of anonymity and confidentiality regarding the data collected. The objectives of the study were explained to the mothers before the data collection, and the checklist was distributed, and data was collected using the paper and pencil method. Ethical clearance was obtained from the Institutional Ethical & Research Committee.

Results

Analysis and interpretation of the data were made according to the objectives of the study. Descriptive and Inferential statistics were utilized to interpret the data. They were further explained under various sections. Table 1 shows the frequency and percentage distribution of sample characteristics. It shows that a maximum of 29 (58%) nursing mothers from rural areas were in the group 25-31 years. On the other hand, a maximum of 24 (48%) nursing mothers from urban areas were in the age group above 32, and the minimum 6 (12%) were in the age group 18-24. When asked about the number of children, 29 (58%) of nursing mothers from rural areas had two children, and 21 (42%) women had one child. On the contrary, urban areas maximum 25 (50%) of nursing mothers from urban areas had two children, and only 1 (2%) had three or more children. On applying the Chi test for homogeneity between the samples, it was found that there was significant homogeneity in Age, Education Mode of Delivery, and Employment status of the nursing mothers residing in rural and urban areas. Out of a total of 50 nursing mothers, Only four mothers residing in the rural area said that they 'went to the gym,' whereas 14 mothers residing in the urban area chose 'to go to a gym' for weight control. There was a

significant association (p< 0.05) between the two groups and the 'use of Yoga' as a strategy for weight control in nursing mothers. Out of a total of 50 nursing mothers, 36 mothers residing in the rural area said that they 'drink water before taking meal' whereas 21 mothers residing in the urban area choose to' drink water before taking meal' for weight control. Only ten mothers residing in the rural area and from the urban area 'consulted a dietician' to control their weight. When asked about 'eating calculation/diet chart,' almost the same number of mothers residing in rural are as 13 and 14 in the urban area responded affirmatively. About 32 nursing mothers residing in the rural area and 30 mothers residing in the urban area said that they 'skipped their meals' to control weight. A similar finding was seen where 34 mothers from rural areas and 33 mothers residing in the urban area 'took short and frequent meals.' Less than half 36 residing in rural areas responded that' they opt for healthy snacking (home-cooked less oily food),' while 41 mothers residing in the urban area using the same strategy to control weight. Both mothers residing in rural 33 and urban areas 36 said that they preferred to 'eat at home than outside' to control weight. Twenty-one nursing mothers residing in rural areas' opted for high fiber diet' while 34 mothers residing in the urban area using the same strategy to control weight. Also, 26 mothers residing in the rural area and 44 from urban areas 'included fresh fruit and vegetables in their diet' to control their weight. When asked, more than half of 36 mothers residing in rural areas responded that they 'take green tea every day' while 41 mothers are residing in the urban area using the same strategy to control weight. About 24 mothers residing in a rural area 'took warm water with few lemons regularly drops' on the other hand, only 16 mothers residing in the urban area used the same approach to control weight. There was a significant association (p<0.05) between the two groups and 'drinking water before taking meals,''consulting a, ''opting for high fiber diet,''including fresh and vegetables in my diet,''take warm water with few lemons drops regularly,''stopped taking Oily foods and Caffeine' as a strategy for weight control in nursing mothers. Out of a total of 50 nursing mothers, only 20mothers residing in the rural area said that they take dinner early evening, whereas 10mothers residing in the urban area chose to take dinner in the early evening for weight control. Only 11 nursing mothers of a rural area and 29 from the urban area took chemical agents/ medication to control their weight. About 20mothers residing in the rural area used to check their weight regularly; on the other hand, 40 mothers residing in the urban area checked their weight regularly. 30nursing mothers residing in the rural area and 34mothers residing in an urban area were motivated to reduce weight. 20mothers from rural areas and 32 mothers residing in urban are as' slept for 6-8 hours straight regularly' to control weight. Only seven mothers residing in rural areas responded that they tried to 'remain stress-free by indulging in leisure activity' while 34 mothers residing in the urban area using the same strategy to control weight. Half, 26, mothers residing in rural areas responded that they drank at least 8-10 glasses of water/ daily, while 34mothers residing in the urban area used the same strategy to control weight. It was therefore clearly evident that nursing mothers residing in urban areas chose more strategies to control weight such as, take dinner in the early evening, take chemical agents/ medications, check their weight regularly, motivated to reduce weight, sleep for 6-8 hours straight regularly, try to remain stress-free by indulging in leisure activity as compared to nursing mothers residing in rural areas. There was a significant difference (p<0.05) between the two groups and 'taking medications for weight loss,' 'checking weight regularly,' and 'being motivated to reduce weight' as a strategy for weight control in nursing mothers. Table 2 reveals the comparison of significant difference between the two groups trying exercise as a strategy adopted for weight control; it was found that there was a significant difference (p< 0.05) between the two groups and 'use of Yoga' as a strategy for weight control in nursing mothers. Table 3 reveals the comparison of significant difference between the two groups trying dietary modification as a strategy adopted for weight control by, on the application of Chi-square test, it was found that there was a significant association (p< 0.05) between the two groups and 'drinking water before taking meals,''consulting a, ''opting for high fiber diet,''including fresh and vegetables in my diet,''take warm water with few lemons drops regularly,''stopped taking Oily foods and Caffeine' as a strategy for weight control in nursing mothers. Table 4 reveals the comparison of the significant relationship between the two groups trying lifestyle modification as a strategy adopted for weight control by, on the application of Chi-square test, it was found that there was a significant difference (p> 0.05) between the two groups and 'taking medications for weight loss,''checking weight regularly,' and 'being motivated to reduce weight' as a strategy for weight control in nursing mothers.

Table 1: Frequency and Percentage distribution of Sample Characteristics N=100

	Urban n = 50	32	18		

* Significant, NS non significant

Discussion

The investigator found that there was a non-significant relationship between the numbers of strategies adopted for weight with socio-demographic variables. Investigators also find that the nursing mothers residing in the urban area adopted more strategies for weight control as compare to nursing mother residing in the rural area. A study of 2,464 in the U.S. similarly found that the women who tried to lose or maintain their weight had adopted exercise more as a strategy than dietary changes. Women who were advised to maintain or gain weight were less as compared to women who were trying to lose weight.[18]

Conclusion

The finding shows that the number of strategies adopted for weight control by nursing mothers residing in the urban area was higher than mothers residing in the rural area. Controlled trials can be conducted to evaluate the effectiveness of specific strategies.

Assess the Knowledge, Practice and Attitude Regarding Nosocomial Infections and their Preventive among Health Care Staff

Blessy Mohandass[1], Amanpreet Kaur[2], Timsy[2], Harmeet Kour[3], Navneet Kaur[3], Pema Choden[3], Aishwarya Thakur[3]

[1]Nursing Tutor, [2]Assistant Professor, [3]B.Sc. Nursing IV[th] Year Students, Chitkara School of Health Sciences, Chitkara University, Punjab, India

Abstract

Nosocomial infections are diseases acquired within 48 hours or more of hospital admission or within 30 days of discharge. The objectives of the study were to assess the knowledge, attitude and practice regarding nosocomial infection and their prevention among health care workers. To determine the relationship between knowledge, attitude and practice regarding nosocomial infection and their prevention among health care workers. To find out association between the knowledge, attitude and practice regarding nosocomial infection and their prevention among health care workers. The research design selected for the study was descriptive research design and a total 100 health care staff were selected as study sample tool was used for data collection. Self-introduction was given and purpose of gathering the information and nature of study was explained before taking information through non probability convenient sampling technique. A self- structured questionnaire, consent was signed by participants. The result revealed that the most of the health care staff 76(76%) had excellent knowledge regarding nosocomial infection and their prevention less than half, 43(43%) had positive attitude regarding nosocomial infection and their prevention. On the contrary, 74(74%) had excellent practice regarding nosocomial infection and their prevention. On applying the spearman correlation test, relationship between knowledge and attitude was found to be significant at $p<0.05$. Hence, researchers concluded that the present study was undertaken to identify the level of knowledge, attitude and practice regarding nosocomial infection and prevention among health care staff in selected hospitals of Punjab. The finding showed that majority of the participants had excellent knowledge and practice. There were gaps in relationship between knowledge and practice and attitude which is found to be not significant at $p<0.05$.

Introduction

Hospital acquired infections which are acquired or caught by a patient in a special location i.e. hospital and acquired after 48 hrs. On patient admission, 3 days of discharge and 30 days after surgery.[1-2] Hospital-associated infections also include occupational infections due to occupational hazard in health care workers.[3-6] There is varioussort of transmissions of these microorganisms and virusacquired through direct contact between patient and doctor as well from patient to nurses and vice versa associated with nursing infected surface, through air such as droplets, aerosols etc. and also commonly through by common vehicles as food and water.[7-9] Nosocomial infections go beyond their effects on morbidity and mortality in every country and have so many economic implications. Infection management should be a part of implementations for all health care workers, not only for their health purpose but also to decrease the prevalence of nosocomial

Assistant Professor, Chitkara School of Health Sciences, Chitkara University, Punjab, India

infections and thus improve patient safety and risks of acquiring infections.[10] Hand washing process leads to complete hand hygiene by healthcare staff has essential importance in the control of infections.[11] Nosocomial infections increase the morbidity, mortality and duration of patients who stay at hospital prices. It is estimated that Nosocomial infections comprise more than 2 million patients per year. Negative outcomes of nosocomial infections differ by type of infection and their related costs.[12] During the 1950s, programs for the surveillance, prevention and control of nosocomial infections were created. However, questions regarding the efficiency and cost-effectiveness of these programs still exist.[13] That is why, this shows that knowledge regarding the effectiveness of nosocomial infection surveillance, prevention, and control is must emphasise on public health: screening, preventing and managing nosocomial infections.

Materials and Method

Research approach for the study was a quantitative research approach, as it allows the investigator to collect and cover data. In this analysis, the Descriptive research design was used, and a non-experimental research design was used to determine the knowledge, practice and attitude regarding nosocomial infections among health care workers in selected Hospitals of Punjab. A total 100 health care staff were selected as study sample tool was used for data collection. Self-introduction was given and purpose of gathering the information and nature of study was explained before taking information through non probability convenient sampling technique. A self- structured questionnaire, consent was signed by participants. In Inclusion Criteria all the health care worker i.e. Doctors, Nurses, Physiotherapist, OT Technician, Lab Technician, Radiologists who are in direct contact with the patient was selected for this study and in exclusion criteria health care staff that were not willing to participate was excluded. Using Non-Probability Convenient sampling technique was selected to select a group of 100 healthcare staff who will be representative of the population being studied.

Results

The study revealed that present research was selected to assess the knowledge, practice and attitude of nosocomial infections and prevention for their health care staff in hospitals. The descriptive research design was selected. Non-Convenient sampling technique was selected for the study. The data was obtained from 100 health care workers who were analysed. The finding of the study for the showed that out of 100 subjects 76(76%) had excellent knowledge regarding nosocomial infection and their prevention and also74 (74%) had excellent practice regarding nosocomial infection and their prevention. So, this concludes that majority of the participants had excellent knowledge and practice and less than half had positive attitude. The second objective of the study findings revealed that relationship between the knowledge, practice and attitude of health care staff regarding nosocomial infection. In current study, on applying spearman's correlation test, relationship between knowledge and attitude was found to be significant at $p<0.05$. The relationship between knowledge and practice and attitude was found to be not significant at $p<0.05$. The findings of the study showed that there was a linear correlation between knowledge and attitude at $p < 0.05$. Overall, there was no correlation between attitude and practice scores of individuals with regard to nosocomial infection prevention and control. The third objective findings revealed that the chi-square value showed that there was a significant association between knowledge and highest educational qualification. No significant association with the selected demographic variables was noted between attitude and practice. The results showed that nurses with a master's degree showed higher mean scores of knowledge than the other two groups.[14] An important statistical difference in mean information scores was found at $p < 0.05$.

Discussion

Discussion deals with the results of the study. In the discussion, the investigator ties tighter all the loose ends of the study. The results and the discussion of the study are investigators opportunity to examine the logic of theoretical framework, the method and analysis. The present study was selected to assess the knowledge, practice and attitude regarding nosocomial infection and their prevention among health care staff in selected hospitals. Descriptive research method was selected and data was collected by self-reported paper and pencil. Data was collected from 100 health care staff that were analysed and interpreted. The relationship between knowledge and practice and relationship between attitude and practice was not significant at $p<0.05$. Chi square value revealed that there was a significant association between knowledge and highest educational qualification. No significant association was seen between attitude and practice with their selected demographic variables.

Table 1: Percentage and Frequency distribution of Knowledge, Attitude and Practice score of healthcare staff regarding nosocomial infections and their prevention N=100

Level of Knowledge Score	**Percentage**	**Frequency**	**Mean**	**S.D.**
Excellent knowledge (9-12)	76%	76	9.64	1.77
Good knowledge (4-8)	24%	24		
Inadequate knowledge (<4)	0%	0

Conclusion

The study concluded that 76 (76%) of the healthcare staff had excellent knowledge and prevention of nosocomial infection Less than half, 43(43%) had positive attitude regarding nosocomial infection and their prevention. On the contrary, 74(74%) had excellent practice regarding nosocomial infection and their prevention. On applying Spearman's Correlation test,

relationship between Knowledge and Attitude was found to be significant at $p< 0.05$. The relationship between Knowledge and Practice and the relationship between Attitude and Practice was found to be not significant at $p< 0.05$. The Chi-square value showed that there was a significant association between Knowledge and Highest Educational Qualification.

Abstract

Cancer is a major health enigma all over the world. In Iraq, cancer caused a large number of deaths and significant morbidity. Nevertheless, limited information is available on how cancer–related literature has developed. This study aimed to analyzethe published research on cancer carried out by Iraqi authors by assessing a bibliometric analysis. Data from 1955 to 2019 was retrieved from Scopus and Google Scholar. The findings of the current study showed significant growth in recent research output regarding cancer, particularly after the 2000s, and more than half of Iraqi publications were internationally published as 79.4% of them. Breast cancer was the type of cancer most targeted by researchers in a percentage of (29%), and the degree of collaboration of Iraqi authors was high(0.808) according to the Subramanyamin method. This study is the first one to analyze Iraqi publications regarding cancer. Our results can help to direct a national knowledge program, planning, and funding assessments. Moreover, to establish new national and international organized collaborations.

Keywords: *Cancer, Lymphoma, Malignancy, Leukemia,Tumor, Iraq.*

Introduction

Cancer is an important reason for morbidity and mortality worldwide regardless of the level of human development. The GLOBOCAN estimates indicated that there were 18.1 million new cases of cancer and 9.6 million deaths from cancer in 2018[1,2]. The percentage of cancer increased by 33% during the period between 2005 to 2015 as a result of population growth and aging[3]. Presently, cancer is the second cause of death internationally and is predicted to hit 27.1 million individuals by 2030 particularly in high-income countries. In Iraq, also cancer is the second leading cause of cancer death following cerebrovascular diseases[4,5]. It is known as an important and growing public health burden in Iraq. Currently, Khoshnaw.et al.,[4] found an increase in annual cancer incidence rates in Iraq, owing to increase of cancer with age and high proportions of hematological malignancies. This increased proportion of leukemia in most Iraqi towns was related to the exposure to depleted uranium, which was used during the wars against Iraq from 1990 until 2010[6-10]. Moreover, Al-Shammari[11] pointed out that the sand particles of Iraq contain toxic substances, which dates back to the pollution resulted from military activities that disassemble the desert sands and change it into light dust. This dust spreads to cities by dust storms. Also,the occurrence of depleted uranium in the Iraqi food chain is proved by evaluating the uranium in animals' organs in various Iraqi cities with the highest level in the south of Iraq. One of the mainlocations of pollution in Iraq is the Al-twaitha nuclear research site. Other researchers recorded that cancer incidences per 100,000 populations of Baghdad have increased; also, it is raised in Basra. Besides,total incidence of breast and lung cancer, Leukemia and Lymphoma, has doubled even tripled. The situation in Mosul governorate is like other regions and the percentage of cancer has further amplified since the Gulf War[12]. Previous review of

Iraqi scientific publications regarding environmental pollutants concluded that Basrah, Baghdad, Falluja, Mosul and Thi-Qar are the most affected towns in Iraq[11].

Productivity in the area of medical terms and research can be measured by some variables. The number of research publications is one of the parameters that can be used to evaluate productivity as well as the quality of research. This can be achieved by using bibliometric analysis[13, 14].

Abibliometrics is a systematic method for assessing research productivity which can help map alterations in the interest of a scientific community over time[15], and can provide visions into both qualitative and quantitative research trends. In bibliometric analysis, a large database, such as Scopus, is used to retrieve, analyze and present the data. In addition, bibliometric analysis shows citations and research collaboration. A citation is accounted for when research is referenced by another peer reviewed research. Citation analysis includes ranking and assessing an article or journal based on the sum of citations it collects. As well as to recognize the highest frequently cited research; bibliometric is also used to determine the impact of journals[16].

Method

Analysis of published researches regarding cancer in Iraq was conducted to analyze the trends of publications.

The Database Used: In this study data from Scopus (Elsevier) was used. Also, Google was searched to gather more articles that not present in Scopus. As well as Scopus and Google Scholar were dependent to collect the citation number of articles.

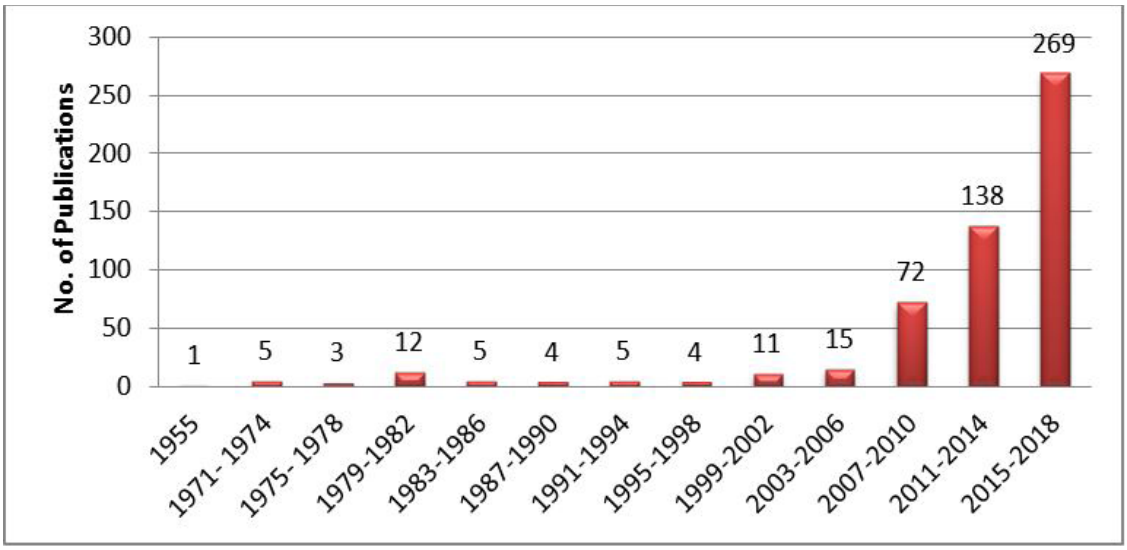
Bibliometric analysis was performed on March 2019 by downloading all the cancer papers related to Iraqi researchers published between 1955 and 2019, using the keywords including ‘‘Cancer’’, ‘‘Malignancy’’, ‘‘Lymphoma’’, ‘‘Leukemia’’, “Tumor”and “Iraq’’. As in any bibliometric study, the retrieved data were arranged as MS Excel file, analyzed and tabulated for presenting the results. The following information was obtained for each article: title, journal name, date of publication, author, number of authors, type of journal, affiliation, and abstract. The data presented to show the annual growth of Iraqi cancer researches, most frequent keywords to explain research interest and publications gaps, national and international research collaboration, most active researchers, journals, governorates and institutions, and the most cited articles among the cancer researches that have the Iraqi affiliation. For calculating the degree of author’s collaboration, the mathematical method of Subramanyamin[17] was followed. C = Nm/ Nm + Ns, Where, C = Degree of collaboration, Nm = number of multi-authored articles and Ns = number of single-authored articles.

Statistical Analysis: T-test was applied to determine the significant differences in the current results at level of 0.05% or less.

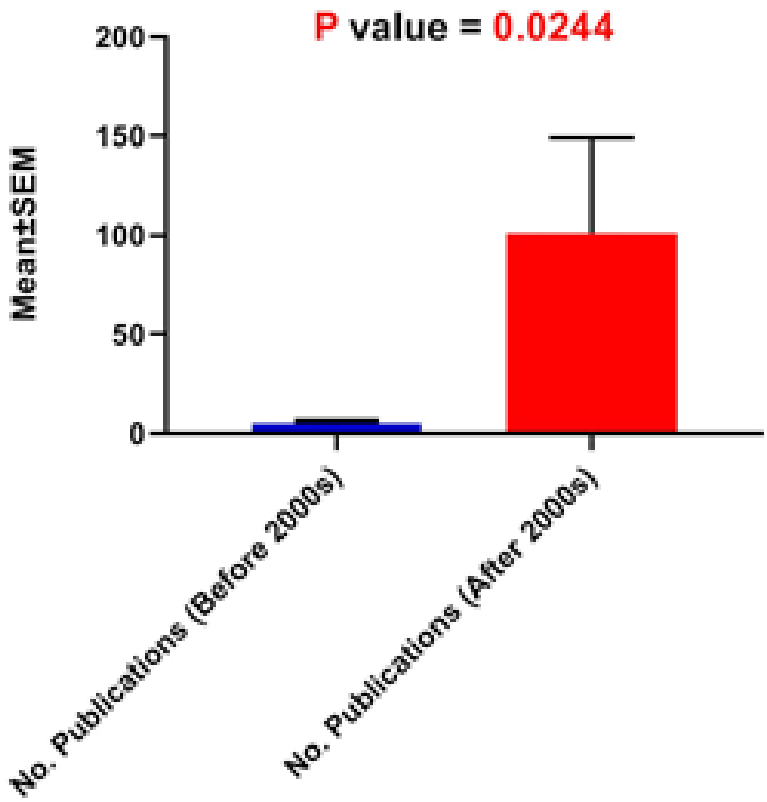
Results

The initial search showed 736 references from both of the considered databases, and the final number of the researches was 544 after removing the duplicates.

The annual growth of Iraqi publications regarding cancer is represented in Figure 1, A. Thegraph shows that the number of publications remained low, followed by a steady phase until 2004. There was a noticeable sharp increase in the number of publications after 2005, which reached a maximum of approximately 269 publications in the last 4 years of the study period, and represented 49.4 % of the published articles concerning cancer by Iraqi authors. The statistical analysis of the present finding confirmed the occurrence of highly significant differences (P-value= 0.024)between Iraqi cancer publication before 2000 and that published after this year as in Figure 1,B.



A



B

Figure 1. A. Distribution of publications by years, B. Comparison between number of publication before and after 2000s.

Breast cancer was the type of cancer most targeted by Iraqi researchers 29.04 %, followed by the articles that cover: cancer as general,female reproduction system, intestinal, and cell line as 17.27%, 6.6%, 6.06%,5.8% respectively, and then the articles that focused on the other types of cancer as shown in Figure 2. There was a significant difference between the number of publications regarding breast cancer and that related to the other types of cancer ($P<0.05$).

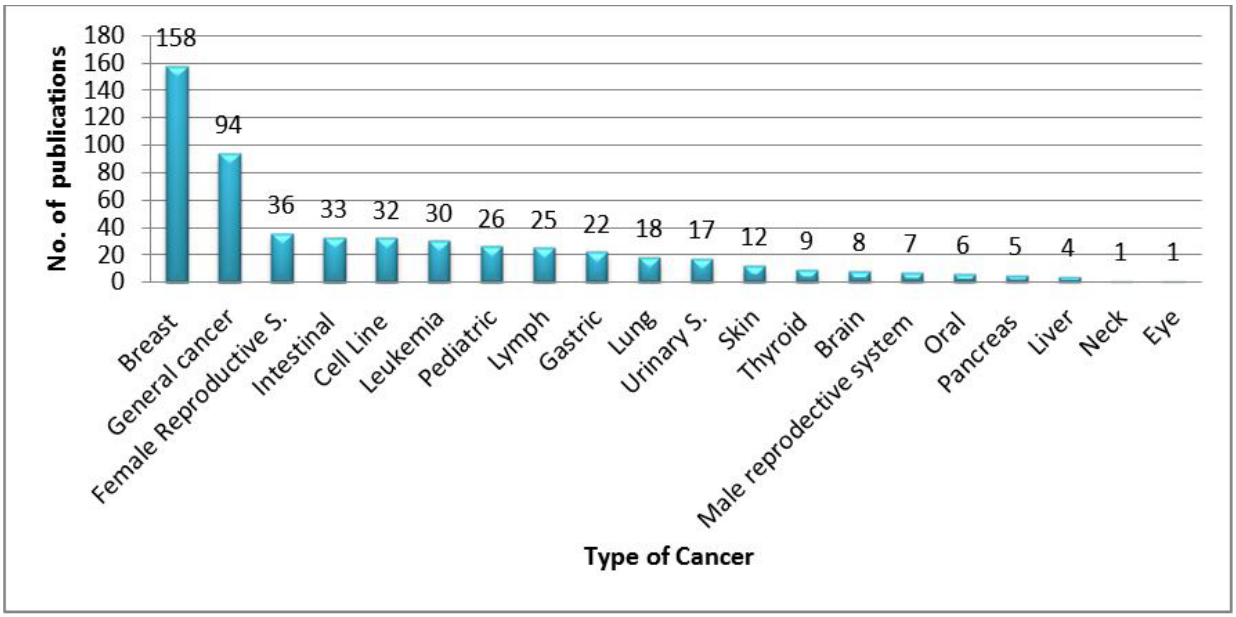


Figure 2. Number of publications by the type of cancer

Moreover,the current study revealed that the majority of articles were published by three authors as 29.59 %, followed by a single researcher as 19.1, and double authors as 17.4% %, these results are summarized in Figure 3. The degree of collaboration of Iraqi authors was high as 0.808.

	Single Author	Two Authors	Three Authors	Four Authors	Five Authors	Six Authors	Above Six Authors
Records	104	95	161	63	43	27	51
%	19.12%	17.46%	29.60%	11.58%	7.90%	4.96%	9.38%

Figure 3. Number of publications related to authority

Regarding the relationship between the number of articles and location, the current finding showed that most publications included all Iraqi patients and didn't restrict to one area which reached 57.5 %,followed by the articles that related to cancer patients of Baghdad (13.7%), Kurdistan (11.3%), and Basrah (7.7%) as shown in Figure 4.

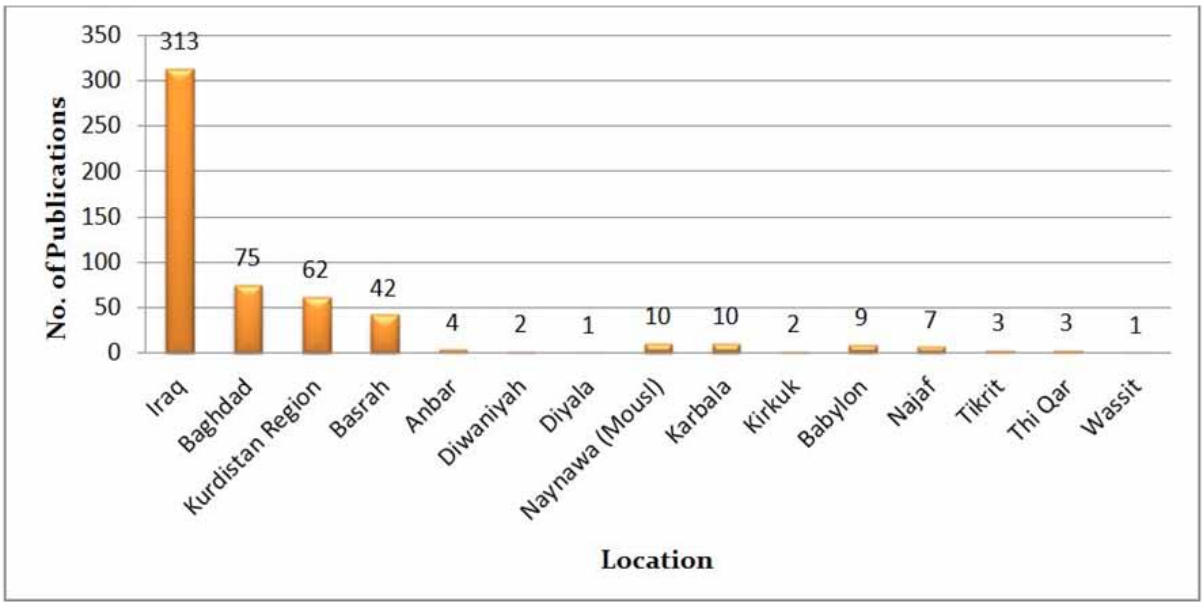

Figure 4. Iraqi cancer publications related to location

Moreover, the majority of Iraqi articles regarding cancer was published in the international journal, in the percentage of 79.4 % compared to national journals as, 20.5 % as shown in Figure 5. The number of internationally published publications significantly differing from that published in national journals ($P < 0.05$). Also, the Asian pacific journal of cancer prevention and the journal of Faculty medicine - Baghdad University have recorded as the journals with most publications.

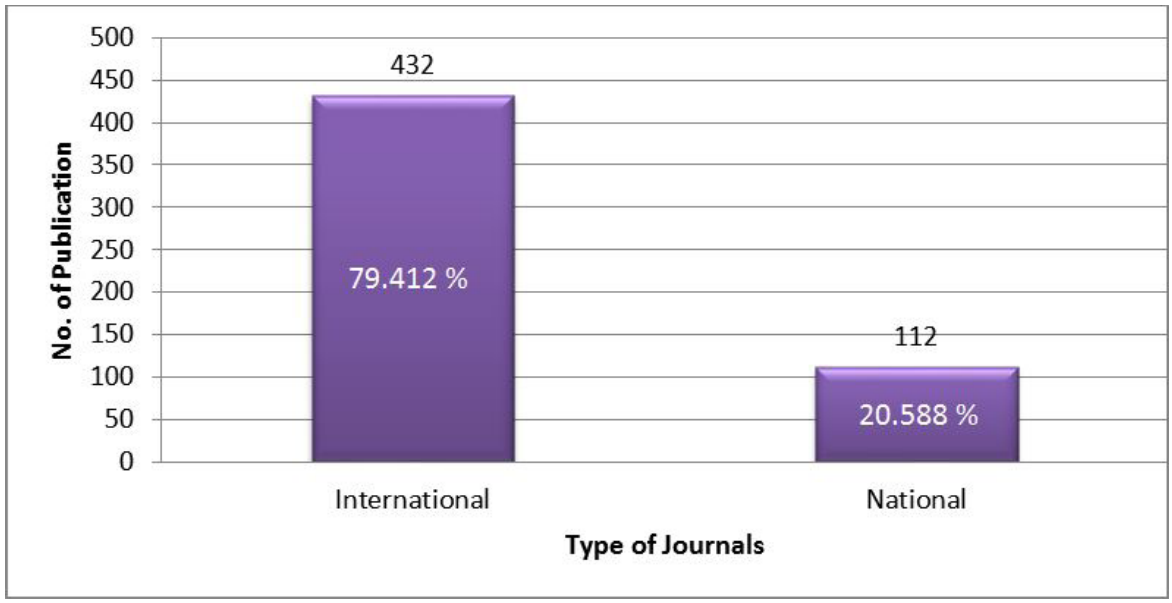

Figure 5. Iraqi publications related to the type of journals

Concerning citations, the current results showed that a total of 213 articles had citations and 331 papers without citations as shown in Figure 6. The top twelve research that ranked by the total number of citations has recorded. The highest citation of the publications was 465 times, that captured by a study related to gastric cancer, published in Gastroenterology in 2007.

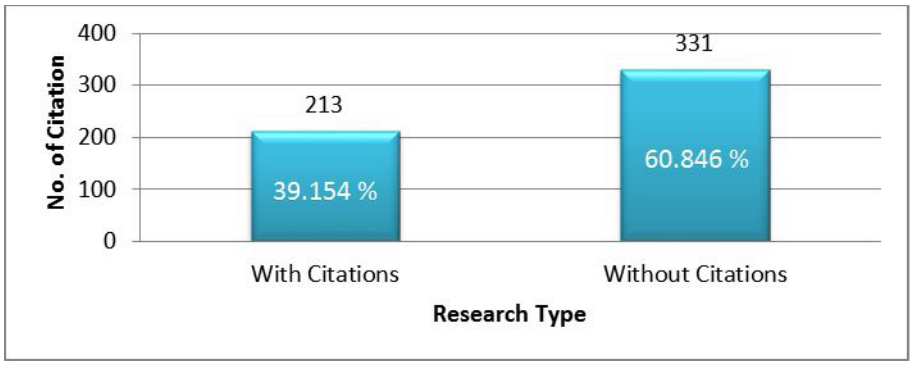

Figure 6. Classification of Iraqi cancer articles depending on citations

Discussion

The current work is the first bibliometric research to analyze the Iraqi publications. Scopus (Elsevier) has used owing to it is inclusive of MEDLINE. Also, Scopus has a huge number of indexed journals (about 23,000 journals). So, the literature recovered from Scopus will be higher than that collected from the Web of Science and others. It is concluded that PubMed remains an important resource for medicine and biomedical sciences[18]. Moreover, Scopus has many characteristics that simplify citation analysis, calculating research partnership, and data arranged by Microsoft Excel for more tabulation and mapping. In fact, several published bibliometric researches have depended upon Scopus to collect their specific data[19-21]. Whereas; Cabral. et al.[22] performed their study using data from the Web of Science Core Collection. The finding of the current study showed that the number of Iraqi articles on cancer was significantly increased over the last years. Several factors may have contributed to this increasing trend. One Important factor for this growth is that the global increase of cancer burden and particularly owing to the noticeable increase in the incidence of cancer in Iraq. Depending on the latest report of the Iraqi ministry of health in 2016, cancer resulted in 9.05% of all death, and it is the second leading cause of death in Iraq after cerebrovascular diseases[23]. Iraq, a war-torn country since the 1980s nowadays has several life challenges that have an impact on the population's development and its civil services. Medical health services and supplies considered as the most affected sectors in this country. In cancer care, for instance, there is deficiency in radiotherapy machines, inadequate funding, and infrastructure[24-25]. Intensity Modulated Radiation Therapy (IMRT) is one of the recent radiotherapy method next to the 3- Dimensional-Conformal Radiation Therapy which became available early 2000s in the developed nations. Despite all the challenges, IMRT was dependent in Iraq in 2013 and it is still running[26]. Furthermore, the degree of collaboration of Iraqi authors as high as 0.8,it is obvious from the present study that co-authorship and teamwork is a common phenomenon among cancer researchers in Iraq.

Regarding cancer types, the present data showed that there was a significant increase in the number of publications related to breast cancer. This finding confirmed the fact that the incidence of breast cancer in Iraq is relatively high, and has been increased during the previous few years, as concluded by a recent epidemiological investigation[27]. Since 2008, breast cancer incidence has amplified by more than 20%, although death has increased by 14% (522,000 deaths in 2012[28]. Similar to many other developing countries, Iraq struggles against the rising burden of breast cancer, the incidence in Iraqi females has risen in the last two decades and the frequency of the disease directed to younger age. *Owing to* lacking the healthcare, infrastructure required to identify,early diagnose, and the availability of treatment for the disease[29-30]. The cases in Iraqi female samplified from 26.6/100,000 in 2000 to 31.5/100,000 in 2009[31]. Moreover, it has been described that the average age at presentation of breast cancer in women from the Arabian region is about a decade earlier than the Western countries[32]. Results of recent investigation suggest that a comprehensive strategy to improve community awareness, surveillance, diagnosis, medication, and palliative careis required to decrease the emergent burden of breast cancer in Arab countries[33].Further more, civilconflicts, added to the already existing social, political, and economic instabilities, certainly increase the burden of breast cancer in some Arab countries[34]. Also Abood[35] concluded that breast cancer onset at

least a decade earlier and at a late stage in Iraqi females when compared to patients of Western countries. Similar findings were documented in comparative research on the characteristics of breast cancer between Iraqi and British women. They pointed out that the mean age of the Iraqi patients at the time of diagnosis was 12 years younger than patients of Britainand also showed ahigher tendency to infect advanced stages[36].

Approximately 79% of Iraqi publications have published in international journals, which represent a high percentage in comparison with articles published in national journals (20.5%). In this context, the current study has some limitations because some articles have published in national journals were underestimated. Furthermore, numerous numbers of Iraqi publications have citation which reflected the importance of these studies, specifically which harvested a large number of citations like Rhead et al.,[37]. Recent findings suggested that in all subject areas, Google Scholar citation data is fundamentally a superset of Web of Science and Scopus, with considerable extra coverage[38].

Conclusion

This study showed that 49% of the number of publications was achieved during the period from 2015–2019. The occurrence of highly significant differences between Iraqi cancer publication before 2000 and that published after this year was also documented. The current study provides valuable insight into the cancer research productivity of Iraqi researchers. Also, it has clarified the trends among the investigation area. Besides this, the high degree of collaboration of Iraqi authors in this aspect, it was highlighted. This work proposes an evidence-based framework on which to initiate future research approaches and academic directions. Highlighting the causative agents of cancer, and how to develop effective control programs, are highly recommended.

Abstract

Covid-19 is a dreadful communicable disease which brought dramatic changes in the Education system globally. Online zoom classes are conducted all over the world to teach and guide the students, so that the academic year will not be wasted. The present study aims to explore the learning experience of nursing students regarding online classes during Covid-19 lockdown periods and to associate the learning experience of nursing students with the demographic variables. A single blinded quantitative study with purposive sampling technique, 250 B.Sc. Nursing students were enrolled in this study. Demographic variables and 23 questions on teaching, learning and difficulties of online classes were used in a 5 point likert scale. Data was collected by sharing the questions in Google dox format to the students. The result of the study revealed high level of satisfaction with maximum score of 63.0 and minimum score of 26.0. This result was significant with the mean value of 46.21 and the standard deviation of 7.32. The association of the learning experience of nursing students with the demographic variables was significant with the year of study of the participants. Hence the research hypothesis formulated in this study was proved.

Keywords: *Covid-19, Online classes, Lock down period, Teaching, Learning, Difficulties, Nursing students experience.*

Introduction

Now a days Covid-19 virus is predominant globally. It is a dreadful communicable disease causing severe morbidity and mortality. Educational system is facing multiple challenges to complete the academic curriculum of 2020. Meticulous planning and guidance from the academician, professor's and teacher's is essential to shift the classroom teaching to online Education. The online Education has several technological advancement which has to be adapted by the teachers and students. India is a developing country giving the best education for all age groups. Online classes through media is valuable. Students are able to communicate with video and audio and clear all doubts with teachers. Home environment will be good to concentrate without emotional and physical strain[1]

In our daily work technology is used in maximum areas and it is the part and parcel of our life. Since the schools and colleges are closed due to lockdown digital and Microsoft zoom classes can be promoted by the universities. It will be flexible and economical[2]. Virtual education is emerging all over the world. Faculties and students has to develop skills to online teaching mode. The parents has to understand and cooperate. So that the academic curriculum can be completed without any loss for the students.[3]

Worldwide around 1.5 billion students are learning in on line mode. Many students do not have wifi connection and high-fi cell phone. The parents must buy the necessary gadgets and they should supervise their children to gain maximum benefit from on line classes. Most of the students are interested in virtual education. The teachers has to provide adequate content in advance. So that the students will be aware of their lessons. Many new advancement are available which can be used by the teachers.[4,5]

Previous studies revealed the control method of influenza. That time school education were modified. [6] Since this online education is new to the students few students reported eye strain and head ache. It can be solved by adjusting the class time.[7]

One of the study done on the impact of Covid-19 and higher education revealed that students were unaware of the classes and there was lack of personal touch and interaction. It can be tackled by the teachers by enquiring the students individually. The parents has to give their full support and motivate their students to cooperate with the current scenario.[8]

Another study done in Maharashtra, India stated that some of the students reported positive impact on online classes and few students reported about lack of concentration. However online classes are very useful except network issues which can be rectified. It is the responsibility of the Universities to support their professor's and teacher's in completion of the curriculum and conduction of on line examination to promote the students.[9] with this great vision the faculty of SRM College of Nursing intended to assess the Nursing students experience regarding online classes during Covid- 19 lockdown period. This study was done after 4 months of online education.

Material and Method

The study was conducted through online among B.Sc. Nursing students of SRM College of Nursing in the month of August 2020. B.Sc. Nursing students 250 were enrolled by purposive sampling technique. Demographic variables include were age, gender, course of study, device used by students to attend online classes, online media used by teachers.

Arround 23 self-structured questions were developed in Google dox form on 3 domains such as teaching, learning and difficulties of online classes in a likert scale with 5 points. In teaching dimension effectiveness of teaching method used by the faculty, response to online classes and the students satisfaction on the online teaching were included. In learning dimension effectiveness of understanding learning process, positive effect regarding university exam, ideas on future online classes and their interest to traditional learning were included. Regarding online difficulties the students over all stress level in online classes, stress due to Covid -19 disease condition, students feelings on online versus traditional lectures, problem on internet issues, time to read and physical problems experienced were included. One open ended question on their suggestions regarding teaching, learning and difficulties faced in virtual classes was included.

After the correction of the tool by the experts in Medical Surgical Nursing, pilot study was done among 10 students in online. The reliability of the tool was tested by test retest method and the r value 0.8 was found to be reliable. The questionnaire was found feasible to proceed to the main study.

The Google form questionnaire was shared to the students in on line to the participants. The collected raw data was spread in the Excel master coding sheet and it was analysed using statistical package for social sciences (spss- 16). The p value of 0.05 level was used for statistical significance.

Results

Regarding the frequency and percentage distribution of the demographic variables revealed majority of the participants among 250 B.Sc. Nursing Students 204 (81.6%) belongs to 18-20 years, females were 206 (82.4%), majority of them 240 (96.0%) used smart phone for the online classes and around 10 (4.0%) students used laptop. Regarding method of teaching majority of the teachers 241 (96.4%) used the zoom app and the Google class room on line was used by 7 teachers (2.8%).

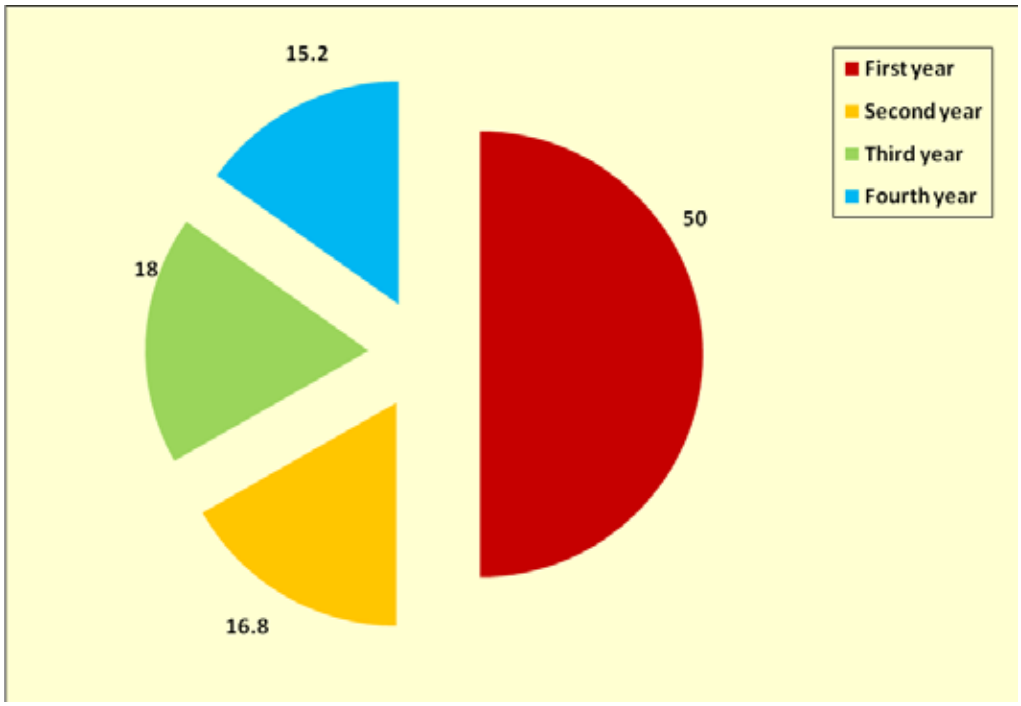

Fig. I. Percentage distribution of year of study of nursing students

Table 1: Frequency and percentage distribution of level of learning experience among nursing students. N = 250

Learning Experience	No.	%
Unsatisfied (1–21)	0	0
Satisfied (22–42)	71	28.4
Highly satisfied (43–63)	179	71.6

The above table reveals majority of the students 179 (71.6%) were highly satisfied and 71 (28.4%) of the students were satisfied with the on line classes done by the teachers.

Table 2: Assessment of mean and standard deviation of learning experience score among nursing students. N = 250

Variables	Score
Minimum Score	26.0
Maximum Score	63.0
Mean	46.21
Standard Deviation	7.32

The above table reveals high level of satisfaction with maximum score of 63.0 and minimum score of 26.0. This result is significant with the mean value of 46.21 and the standard deviation of 7.32. Hence the study is significant.

The association of the learning experience of nursing students with their demographic variables was significant with the year of study of the participants. Other variables like age, gender,course of study, device used by students to attend online classes, online media used by teachers were not associated with the demographic variables.

Discussion

The present study on assessing the experience of Nursing students about online classes during Covid -19 lock down period is the need of the hour. This is the first time the Nursing faculty and students of SRM College of Nursing were exposed to online classes. It is believed that during this lock down period students are having many difficulties to understand the classes. There is no motivation, no social interaction and the students are psychologically upset due to the distraction and lack of support at home. Some of the students have very poor net work coverage and the students had head ache due to continuous online education mode. The students were convinced by the teachers and by weekly 3 classes and individual phone calls and watsup messages students were happy to cooperate with the classes.

In this study 250 B.Sc. Nursing students participated. The findings of the present study revealed that majority of the students 179 (71.6%) were highly satisfied and 71 (28.4%) of the students were satisfied with the on line classes done by the teachers. The result of the study revealed high level of satisfaction with maximum score of 63.0 and minimum score of 26.0. This result was significant with the mean value of 46.21 and the standard deviation of 7.32. The association of the learning experience of nursing students with the demographic variables was significant with the age group of the participants. Hence the research hypothesis formulated in this study was proved.

This result is supported by the study of**Dr. Anjana kannankara** (2020) on E-learning the Best Bet during lockdown. The study states that online learning will facilitate to face the challenge of working in this new environment as well as embrace the new opportunities to everyone. Hence, this study can be done in other areas of education to facilitate the online education.[10]

Conclusion

The present study high light the success of the online teaching and learning programme of B.Sc. Nursing students during this Covid-19 pandemic period. The teaching faculty and the students has to adapt new learning method for the completion of the curriculum. The parents has to help and motivate the students in continuous learning process during this critical situation. This study can be done in other areas of education to develop knowledge and confidence among the students.

Acknowledgement: The Dean and team of Medical Surgical faculty conceived and designed the study and collected the data. Analysis was done by Mr. Arvind statistitian. Interpretation and drafting of the article was done by Dr. T. Suseelal, P. Malarvizhi and Mr. P. Vijai Daniel Raj. Dean, college of Nursing has done the final revision and approval of version to be published.

Conflict of Interest: The authors declared no competing interest.

Ethical Clearance: Ethical approval was obtained from the SRM University research committee who follows WHO standards and the 1964 Helsinki declaration and its later amendments.

Study of Anxiety Levels among Occupational Therapy Students During Various Academic Assessments

Chirag Pincha[1], A.V. Anuja[2], A. Sangeetha[3], M. Karthika[4], Samuel Sundar Doss[5]

[1]MBBS Student, [2]Assistant Professor, [3]Assistant Professor, Department of Physiology, Saveetha Medical college & Hospital, Thandalam, Chennai, [4]Assistant Professor, Department of Physiology, Dhanalakshmi Srinivasan Medical college & Hospital, Perambalur, [5]Tutor, Department of Physiology, Saveetha Medical college & Hospital, Thandalam, Chennai

Abstract

Test anxiety among university graduate students is significant and generates public interest. Test anxiety leads to cognitive symptoms such as racing thoughts, nausea, blankness and difficulty in retrieving information. When stress is experienced in excess it contributes to anxiety before and during exams and eventually affects academic performance.

Aim: The aim of the study is to evaluate the anxiety levels among occupational Therapy students during various academic assessments.

Method: A total of 160 Occupational Therapy Students participated in this study. The Anxiety Inventory was used to evaluate the anxiety level.

Results: The results indicated that anxiety affects students performance during theory & practical assessments and was found to be statistically significant ($p<0.0001$).

Recommendation: It is suggested that the pattern of conducting examinations may be modified to reduce student test anxiety.

Keywords: *Test anxiety, Academic Assessments, Occupational Therapy Students.*

Introduction

One of the most pervasive reactions that students have to encounter during different types of academic assessments is test anxiety[(1)]. Test anxiety by definition is a set of phenomenological, psychological, and behavioural responses that accompany possible negative consequences in a person[(2)]. Academic stress is an emerging problem across countries, cultures and must be viewed in detail[(3)]. Every student has a dream to lead success, family pride & social mobility [(4)]. Test Anxiety is a bi-directional structure of affective & Cognitive elements[(5)]. The cognitive component is Self cretinism and negative effects of failure during exams[(6)]. The student anxiety during the test causes an inability to recall information, rise in heart rate, nervousness, sweaty palms[(7)].

Stress is not necessarily harmful, stress can motivate and it is a state of mental or emotional strain due to adverse or demanding circumstances[(8)]. The signs of stress which is experienced by most students before and during the examination are irregular sleep, tiredness, stomach upset, loneliness, feeling restless, difficulty in recalling whatever studied, panic when the question paper is given and difficulty answering it. The most stressful factors identified in educational institutions

Mobile No.: 9710702121

are evaluations and competitions between students and students' academic failures[9]. Identifying the influencing factors on student academic performance is a challenge for teachers[10]. Since the test scores are very significant for academic and carrier progress, the students are naturally under immense pressure to achieve high scores so the test anxiety becomes an universal experience in contemporary society, there seems to be some connection between the level of anxiety, experienced by the learners and their scores[11].

Aside from academic factors, other influencing factors include financial factors, health problems[12]. This anxiety during or before exams have a major impact leading to lack of decision making and gives rise to nervousness and might also lead to suicide[13]. It is perceived that to reduce anxiety levels in students before & during exams constructive learning method only will help the students to become independent and develop their own concepts pertaining on the subjects[14]. This anxiety many of the students face before their exams may interfere with their ability to score marks[15]. This study focuses on the anxiety levels of different age groups among occupational therapy students.

Materials

A cross-sectional questionnaire based study was conducted among occupational therapy students during the academic year 2019-20 at Saveetha Medical College and Hospital after obtaining ethical approval by the board of the institute (SMC/IEC/2019/22). Informed consent of the participants were obtained. A total of 160 students between 18-24 yrs participated in the study. Students on depression medication or any physical anxiety and depression were excluded from the study. The Test Anxiety Scale Questionnaire by Nist and Diehl (1990) was used to measure the level of anxiety. This scale consists of 10 items. Each item is scored based on how often they have experienced the mentioned signs of test anxiety. The scoring consisted of a 5-point scale, in which 1 was (never), and 5 (always) Items were then summed for a total score, which ranged between 10 and 50, where low scores between 10-19 indicated that students do not suffer from test anxiety, mid-scores between 20-35 indicated that although students exhibit some of the characteristics of test anxiety, the level of stress and tension is healthy and high scores over 35 showed that students experience unhealthy levels of anxiety. The questionnaire included demographic details, age, sex and symptoms before and during exams. Students those who are having history of neurological disorders, psychological disorders were excluded from the study. Signs of nervousness such as sweaty palms, shaky hands right before the test and panic attack before exam, going blank and not able to recall before the exam, trouble sleeping the night before the exam were collected. The data was analyzed using SPSS 20.1.

Results

The present study was done to assess anxiety among Occupational therapy students during different academic assessments and the results are as given below.

Table I : Demographic details

	Theory	Practicals	Mean & SD
Age:			
18 yrs	11	11	19.5 ±0.92 (Theory)
19yrs	21	24	19.5 ±0.89 (Practicals)
20 yrs	44	44	
Sex:			
Male	11%	12%	
Female	66%	71%	

Table I show that more students were in the age group of 19 and 20 yrs with mean age 19 ±0.92 years. of the participants >65 % were females.

Table II: Comparison of Anxiety scores between Theory and Practical Assessments

Assessment	Low score	Moderate score	High Score	Chi-Square (x^2)	P Value
Theory n = 77	1%(0.96)	4%(16.84) (9.79)	72% (59.19) (2.77)	24.333	<0.5
Practical n = 83	1% (1.04)	31% (18.16) (9.09)	51% (63.81) (2.57)		

Table II indicates a high degree of anxiety level (High score > 36-50) among occupational therapy students during theory and practical assessment. The results show statistically significant. ($x^2 = 24.223$, $p < 0.5$).

Table III: Comparison of test anxiety among Occupational students during Theory & Practical assessment.

Parameters	Theory (Mean±SD)	Practicals (Mean±SD)	t-test
1. Do you have any viable signs of nervousness such as sweaty palms, shaky legs, right before the test?	2.18±0.93	2.44 ± 1.00	p = 0.1150 t = 1.5946
2. Do you experience butterflies in your stomach before the exam	2.00±0.86	2.32±1.04	p = 0.039* t = 2.0744
3. Do you feel nauseous before the exam?	1.49±0.87	2.90±0.94	p = 0.0001 * t = 9.8069
4. Does your mind go blank before the test?	2.43±0.87	2.35±0.89	p = 0.5672 t = 0.5734
5. Do you remember the information that you blanked out in the exam hall and remember as soon as you get out of the exam hall?	2.41±0.82	2.60±0.93	p = 0.2253 t = 1.2225
6. Do you feel panicked knowing that the exam is time-limited and get more nervous and write the exam worse	2.20±0.80	2.11±0.87	p = 0.4566 t = 0.7483
7. Do you feel that you have done your test badly as soon as you leave the exam?	1.93±0.60	2.15±0.88	p = 0.0399* t = 2.0915
8. Do you feel nervous if the teacher stands next to you and then You can no longer answer the questions?	2.01±0.92	2.23±0.92	p = 0.1290 t = 1.5348
9. Do you feel you take most of the time in answering the questions or to decide to hand in the paper or not?	2.12±0.73	2.07±0.78	p = 0.6890 t = 0.4018
10. Do you feel constantly restless throughout the test (moving your feet playing with your pen looking around the room and looking at the clock)	2.12±0.92	2.57±1.13	p = 0.0183* t = 2.4123
11. Do you feel that the invigilator/teacher is watching you?	2.00±1.83	2.27±0.96	P = 0.0864 t = 1.7376

Table III explains the student mean score of test anxiety relation between theory & practical assessment.

The students faced the dreaded stomach before practical exam (p= 0.039*), nausea (p= 0.0001*), felt bad that they performed badly once they left the exam hall (p=0.0399*) and the students were constantly restless throughout the test **(**p =0.0183*). The results were found to be statistically significant. The study also showed that students were more nervous to practical viva when compare to theory 52.4% were always nervous, 24.4% were often nervous and 18.3% were nervous sometimes during practical exam. A majority of participants never felt 51.2% that viva is easier to score marks than theory and practical exam 39% and 8.5% sometimes and often felt that viva is easier to score respectively. The results also showed that 30 % of participants during Theory exam never felt has forgotten everything and may fail while the remaining 70 % has forgotten and felt may fail. Also only 23.7% of participants do not feel more nervous sitting in first row during the exam remaining 76.3% feel more nervous sitting in first row.

Discussion

Exam anxiety may cause cognitive changes like difficulty in memorizing, inability to recall information's etc[16]. Exceeding level of test anxiety results in mental, physical discomfort leading to focus problems and mental disruption[17]. Diversity of findings found in various researches indicates that different factors cause test anxiety in students[18]. Some authors suggest that test anxiety may worsen cognitive resources like attention and working memory, thus preventing students from concentrating on the exam[19]. The present study revealed that majority of participants were female in the mean age group of 19.5 ±0.92 yrs (Table I). Studies repeatedly found due to higher levels of emotion in females generally report higher levels of anxiety[20]. Arch reported a very high prevalence of anxiety and depression (70%) among medical students in Pakistan[21]. Another study has shown that academics and taking exams are the most powerful stresses in medical and paramedical students[22]. The result of this study was identified to have a high level of anxiety score and the

highest mean score during practical examinations. This result is similar to David & Ross[23] who proposed that a very high proportion of students had some form of test anxiety. More recent explanations refer to the fact that anxiety may affect students' motivation and undermine their learning strategies [24]. Whatever the cause, test anxiety may reduce students' academic achievement by interfering with their exam preparation, their performance while taking an exam, or both.

Conclusion

The study shows that anxiety affects students' performance during theory & practical assessments and was found to be statistically significant. Hence it is suggested that the pattern of conducting examinations may be modified or certain relation techniques can be applied before exams to reduce student test anxiety.

Limitation of the Study: Further studies including a large number of medical and paramedical students should be done.

Plasma CD4 Count and Duration ARV as a Predictor of Virological Failure Amongst AIDS Patients

Choirina Windradi[1,2], Erwin Astha Triyono[1,3], Musofa Rusli[1,3]

[1]Faculty of Medicine, Universitas Airlangga, Surabaya 60131, Indonesia, [2]Senior resident of Department of Internal Medicine, Faculty of Medicine- Dr. Soetomo Teaching Hospital, Universitas Airlangga, Surabaya 60131, Indonesia, [3]Tutor of Tropic and Infection Department of Internal Medicine, Faculty of Medicine- Dr. Soetomo Teaching Hospital, Universitas Airlangga, Surabaya 60131, Indonesia

Abstract

Background: The 90-90-90 strategy to overcome the HIV/AIDS (*Human Immunodeficiency Virus/Acquired Immunodeficiency Syndrome)* epidemic in the world still has challenges because 20% of people live with HIV/AIDS (PLWHA) received anti retroviral (ARVs) are at risk of virological failure. This study describes and analyzes the factors that influence the occurrence of virological failure in AIDS patients who have taken ARVs.

Method: A hospital based cross-sectional study and retrospective medical record review in Dr. Soetomo Teaching Hospital Surabaya from January 2017 until December 2018. Virological failure is plasma viral load greater than 1000 copies/ml.

Result: According to data analysis for each variable, we used a CD4 (*Cluster of Differentiation)* cut-off of 134 cells/µl and ≥ 20.5 months for virological failure. There was a statistically significant relationship between CD4 cell count 95% CI (1.33-11,281) p 0.010 and duration of ARV (1,396-11.78) 95% CI p 0.01. Summation of total score from both variables has a p value <0.001 which means the total score of the two variables is significant as a predictor of virological failure. The total area of the ROC curve is 73.6% with a sensitivity of 81.5% and specificity of 44.4%.

Conclusion: The duration of ARV consumption and CD4 cell count have an effect and can be an initial evaluation of the occurrence of virological failure.

Keywords: *Virological Failure, HIV, AIDS, ARV.*

Introduction

Human Immunodeficiency Virus (HIV) is a virus that causes serious health problems in the world. In Indonesia, in 2018 an increase in the prevalence of people with HIV/AIDS (Acquired Immunodeficiency Syndrome) (PLWHA). The strategy in the world to overcome the epidemic is 90-90-90 which means that by the end of 2020 90% of all patients is diagnosed of HIV, get antiretroviral (ARVs), and suppression of viral load (viral load/VL)[(1)]. Yet, Indonesia could only reached 47% to diagnose of HIV status, 31.9% of ARV accesses, and 0.6% suppression of viral load[(2)].

ARVs play an important role in achieving the 90-90-90 target. However, one of the challenges in the management of HIV is virological failure. About 20% of PLWHA experience virological failure despite taking ARVs[(2)]. Meanwhile, virological failure is associated with a 40% risk of death[(3,4)].

Extensive research on the factors associated with virological failure has been carried out. In a case control study in Ethiopia, CD4 counts <200 cells/mm^3, first-line ARV regimens and adherence had an important role in the occurrence of virological failure[5]. Thus, the existence of other known risk factors in the population from this study is expected to provide a new perspective in the management of PLWHA as well as interventions, especially in Indonesia.

The results of this study are expected to be able to explain the factors that influence virological failure in PLWHA who has received ARVs.

Materials and Method

Study area, design, time,population: A hospital based cross sectional study with a retrospective approach in HIV patients at outpatient clinic UPIPI (Intermediate Care Unit and Infectious Diseases) Dr. Soetomo Hospital Teaching Surabaya. This study is conducted from January 2017 until December 2018.

We collect medical record of HIV/AIDS patients aged ≥21 years who suspicious suffered from virological failure based on the criteria of clinical, immunological, virological failure, and non-compliance with taking ARVs at least for 6 months. We ruled out patients who did not have plasma CD4 count and viral load data at the time of study. Sample was carried out in a consecutive manner from population met the inclusion criteria and there were no exclusion criteria.

Terms of Operational: Virological failure is a condition in PLWHA that shows failure to suppress the amount of virus in the blood after taking ARV for at least 6 months, a viral load of more than 1000 copies/ml. Good adherence is the number of drugs taken compared with the drugs given every month ≥95%.

Result

Sociodemographic Characteristic of Patients: A total of 72 patients met the inclusion and exclusion criteria were included in this study. of these, 51 were men while 21 were women. The average age (SD) of patients in this study was 39.04 (9,964) (range 24-67 years). The average duration of ARV consumption was 29.3 (32.3) (range 6-156 months). 54 patients had primary education (75%) while 18 (25%) patients continued through college. 48 (66.7%) patients received FDC and 24 (33.3%) patients received regimens based on TDF/NVP, ZDV/NVP, ZDV/EFV, ZDV/LPV, TDF/LPV, TDF/RPV, and FTC/LPV. The majority of patients in the study had risk factors for unsafe sex (heterosexual or homosexual) (93%). 55 patients (76%) were in stage III-IV. Opportunistic infections that accompanied the patients in this study were hepatitis C 3 (4%), Toxoplasmosis 8 (11%), PCP 13 (18%) and tuberculosis 13 (18%) **(Table 1).**

Virological failure and Associated Factors: Of the variables associated with virological failure, CD4 cell count and duration of antiretroviral drugs have a significant relationship. The normality test from the CD4 data shows p> 0.05 which means that the CD4 data has a normal distribution while the duration of ARV consumption has an abnormal data distribution (p <0.05). The CD4 test was then continued with Mann Whitney **(Table 2)** data analysis while the duration of ARV consumption used an independent t-test **(Table 2)**.

Using data analysis, the cut-off for CD4 ≤134 cells/ul was obtained while the duration of ARV consumption was ≥ 20.5 months. Statistical analysis for CD4 data and ARV duration using the SPSS 20 program showed a significant relationship between CD4 cell count (p <0.05) and duration of ARV consumption (p <0.05) with virological failure. We use logistic regression analysis to calculate SE and β to formulate a predictive total score **(Table 3)**. From the results of the analysis, each score of 1 was obtained for CD4 cell count and duration of ARV.

Summation scores to each of the research subject variables was described as total scores that passed on to logistic regression analysis. The next assessment is the discrimination of the scoring model obtained p value <0.001 with an area under curve (AUC) of 73.6%. The cut-off of this model shows a sensitivity value of 81.5% and a specificity of 44.4% **(Picture 1)**.

Table 1. Factors Contribute to Virological Failure

Variable	Group		p-value
	Failure n (%)	Non Failure n (%)	
Gender			
Men	18 (35,2%)	33 (64,8%)	0,598
Woman	9 (42,8%)	12 (57,2%)	
Education			
Primary	21(38,9%)	33 (61,1%)	0,782

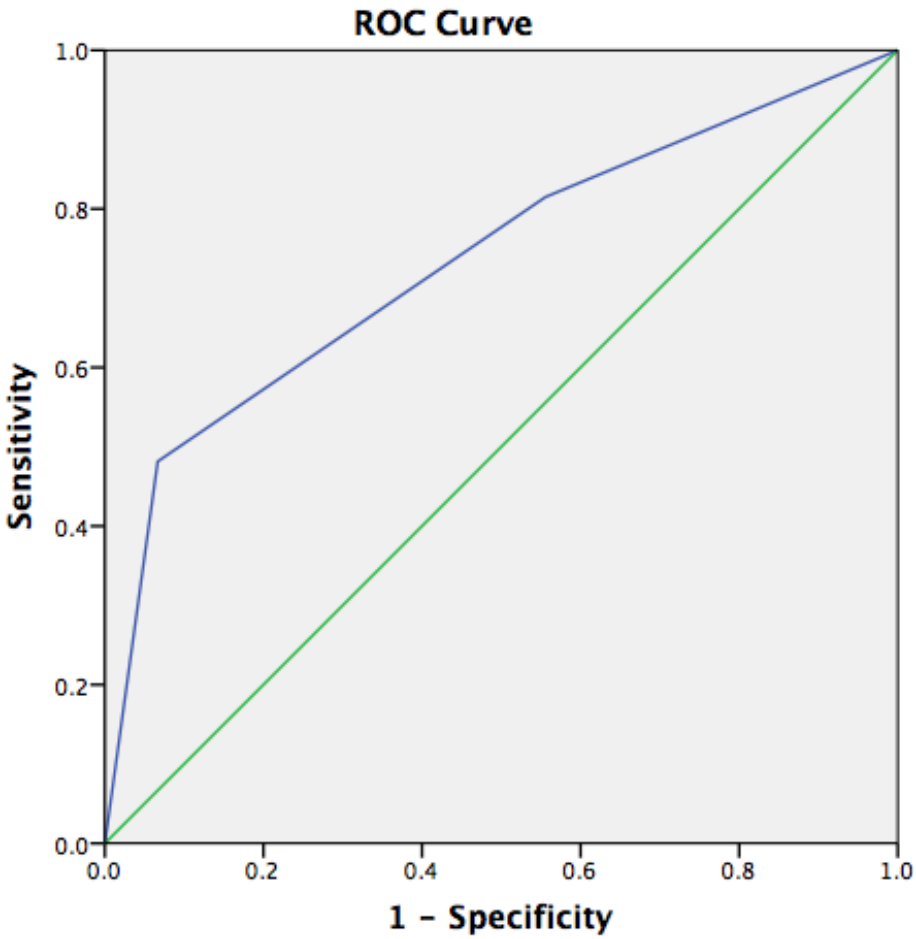
CD4 Count	1.400	0.544	2.573	1.03	1
Total score					**2**



Picture 1. ROC Curve For Total Score of Plasma CD4 Count and Duration ARV Consumption

Discussion

The results of data analysis for each variable that affects virological failure, only CD4 and duration of ARV have a significant relationship. The total predictor scores of the two variables have significant results so that the score model can assist clinicians in evaluating suspicion of virological failure. The assumption of this score is that patients with CD4 counts ≤134 and duration ≥ 20.5 months have a risk of virological failure with a sensitivity of about 81.5%.

CD4 T cells are known as components of the humoral and cellular immune responses to exogenous antigens. HIV binds to CD4 molecules on the surface of helper T cells (Th cells) and replicates on them. This causes damage and decreases in CD4 T cell counts[6].

Several hypotheses in 1980 stated that the decrease in the number of CD4 T cells was caused by rapid damage due to resistance to HIV. Through this theory there is a balance of homeostasis when CD4 T cells are damaged by HIV, it will be offset by T cell production. However, this balance mechanism will be disrupted when there is no production response to T cells due to the burden of T cell production. Therefore, during HIV infection, around one billion HIV particles are produced each day, causing an increase in the number of infected CD4 T cells. Every time a memory CD4 T cell is infected, it will undergo an elimination process that causes a decrease in the number of CD4 T cells. The mechanism of apopotosis of infected CD4 T cells supports this hypothesis but naïve CD8 T cells and uninfected CD4 T cells that participate in elimination in the asymptomatic phase cannot be explained by this process[6].

The second hypothesis that causes CD4 T cell decline in HIV is chronic immune activation under hyperimmune conditions. This condition induces an increase in the division of CD4 cells, CD8 cells, NK cells, and B cells. T cell division also increases the

ability to renew itself which can increase the number of cells. The hypothesis of the number of T cells decreases due to activation because the activated CD4 has a short life and disappears due to apoptosis. HIV causes its targets and increases replication through chronic immune activation. HIV activates immunity through Nef, Tat, Vpr, Vpu and pro-inflammatory cytokines. The presence of HIV DNA in the cytoplasm will activate pro-inflammatory cytokines so that the HIV virus will cause chronic immune activation[6].

Patients with low CD4 cell counts have a nine-fold risk of virological failure than patients with high CD4 cell counts (> 200 cells/mm^3). This finding is consistent with research in Switzerland and Uganda. In theory, there is an inverse relationship between CD4 cell count and replication and viral load. Patients with impaired immune status have a risk of opportunistic infections as well as low immune status and high levels of viral replication. Patients with CD4 counts ≤199 have a risk of virological failure OR 10.09 95% CI (2.47-41.29), CD4 200-349 OR 2.94 95% CI (0.86-10.07), CD4 350 -499 OR 0.83 95% CI (0.18-3.8). CD4$^+$ T cells are the majority of cells infected with HIV. The HIV virus causes adverse effects on the level and proportion of these cells in lymphoid tissue and blood. Some of the mechanisms adopted by viruses that cause a reduction in CD4$^+$ lymphocyte counts include dysregulation of cell proliferation and homeostasis. HIV-1 infection alters CD4 T-cell homeostasis, which is a balance between the rate of production and cell death. This results in a higher rate of cell damage compared to production, contributing to a decrease in CD4$^+$ T cells. HIV infection also interferes with the production of thymic and hematopoietic progenitor cells, causing cell death through the release of the gp120 virus protein. HIV infection causes a cycle that involves activation and death of the immune system then drives HIV replication[7].

Adherence is an important factor for the success of therapy in AIDS patients. Interruption of ARV consumption, especially the NNRTI regimen, causes an increase in virological failure and antiretroviral resistance. This observation reflects the low genetic barrier to antiviral resistance to NNRTIs, such as prolongation of the plasma half-life of NNRTI, which causes the plasma concentration of NRTI therapy to decrease. In areas with limited access to antiretroviral therapy, interruption of therapy causes the total cost of treatment to be more expensive due to difficulty accessing health services, distribution difficulties and drug storage. The risk of non-compliance leads to virological failure OR 3.6 95% CI (1.2-11)[8]. Unfortunately, bivariat analysis of adherence in this study did not show a significant relationship.

When adherence decreases, the dose of the drug becomes intermittent, causing exposure to single and multiple drugs to have a longer half-life. A similar situation occurs when PLWHA stop all antiretroviral drugs[9]. In this study, if the duration of antiretroviral drugs was assessed based on the duration of antiretroviral consumption, a significant relationship was found ($p < 0.001$) which means that the longer the patient took antiretrovirals the lower the adherence to antiretroviral consumption.

Limitation of this study were this research was conducted at the outpatient clinic UPIPI Dr. Soetomo Teaching Hospital Surabaya, which is a tertiary referral health facility so that the exclusion inclusion criteria cannot describe the condition of HIV/AIDS patients extensively, CD4 evaluation data and viral load are not all tested periodically so they cannot describe the tendency of failure and suppression of virological, incomplete medical record data regarding reasons for selection, replacement of antiretroviral drugs and side effects of antiretroviral drugs in patients, unable to evaluate virological failure based on patient adherence every 6 months and the underlying reasons. Furthermore, the total score predictor model shows an area under curve of only 73.6% indicating that there are other variables that can affect virological failure.

Researchers hope that with these findings an evaluation of virological failure can be carried out intensively. This will have an impact on the patient's clinical course, the risk of drug mutations and the mortality of AIDS patients. A study with patient compliance interventions is needed to study the relationship of adherence to virological failure in HIV/ AIDS patients.

Conclusion

Patients with CD4 ≤134 cells/ul and duration of ARV consumption ≥ 20.5 months have a risk of virological failure.

Acknowledgments: We would like to express our deepest gratitude for the patients who participated in the study and the work of the Outpatient Clinic UPIPI Dr. Soetomo Hospital Teaching and support research. The

tremendous contributions on the part of the counselors, medical records staff, have been essential to the success of this study.

Conflicts of Interest: The authors declare no conflicts of interest in this HIV/AIDS research.

Source of Funding: This research did not received any endorsement or funded by specific grant. All the funding came from researchers.

Ethical Consideration: Ethical clearance was obtained from Ethics Committee Dr. Soetomo Teaching Hospital Universitas Airlangga and official letter was submitted to the Dr Soetomo Hospital administration prior to data collection.

Physiotherapy Students Willingness to Report Misconduct to Protect the Patient's Interests in Chennai

D. Malarvizhi[1], Bhagya Lakshmi K.[2], Hariharan S.[2]

[1]Prof. Dean, [2]BPT IV YEAR Student, SRM College of Physiotherapy, SRM Institute of Science and Technology, Kattankulathur, Chengalpattu, Tamil Nadu, India

Abstract

Background: Applying the ethics in practice is more essential than just learning it. Any sought of misconduct to the patient is not just an ethical issue but it will also degrade the professionalism and it brings a sense of insecurity in patients and this will slow down the progress of treatment. So it is not only important to avoid the ethical issues and misconduct but it is also necessary to stand against ethical issues that happen within the organization that may done by colleagues or higher authorities without any dilemma. **OBJECTIVE:** This study aims to find out the difficulties and dilemmas of the physiotherapist in ethical decision making and disclosing the misconduct of their colleagues without any hesitation. **METHODOLOGY:** A close ended questionnaire was used to assess the willingness of the student physiotherapist to expose the misconduct which might be an internal or external disclosure. The questionnaire consisted of two clinical scenarios which were most likely to arise in a work place. Each scenario consisted of 5 questions that rated the severity, likelihood of confronting, internal disclosure, external disclosure to the association and external disclosure to media. The scoring was based on five point likert scale. It was a study that was done with convenient sampling method. The questionnaire was given to 100 Physiotherapy students in Chennai of both the sexes who were willing to participate in the study.**RESULT:** From the statistical analysis, there is a significant difference obtained for the likelihood of reporting the manager's misconduct than colleague's misconduct. Also their willingness to report internally within the organization is greater than that of reporting externally to the association and to the media.**CONCLUSION:** Ethics being a part of Physiotherapy curriculum, these students have well understood the ethical and professional behavior and have good ethical acceptance. Hence we conclude that the students do understand the seriousness of any misconduct of a therapist to the patient and are willing to expose any misconduct they encounter to the internal or external environment.

Keywords: *Ethics, Students, Physiotherapy, Misconduct, Ethical dilemma*

Introduction

Whistle blowing is usually defined as the reporting "by organization members (former or current) of illegal, immoral, or illegitimate practices under the control of their employers to persons or organizations that may be able to effect action" [1]. Reporting any sought of unethical behaviour is more inevitable and essential in the field of health sciences as it is concerned with human lives. Whistle blowing largely helps in the reducing the rates of misconduct in future [2,3].But still blowing a whistle against the organisation or colleague or a superior is a major dilemma faced by an individual because when blowing a whistle, it not only involves the whistle blower and the organisation but it also involves the patient who is actually affected, this will lead to deterioration of the hospital's fame. This will put the whistle blower at risk[1,2]. All though whistle blowing is a moral behaviour, it will risk the life of the one who reports the misconduct. The person who voluntarily reports the misconduct might be exploited and might end up in losing his livelihood[1,4]. Despite these consequences it is to be noted that those who are with high self-ideals are the one to report the misconduct as they are ones intolerable to the unethical behaviour[4]. It must also be noted that a person will hesitate to report his friend if found guilty because of their bond or because of the fear that they might get caught one day[5].

When a person is dishonest or unethical during his student life then there are high chances that he will be more deviant during his professional life [5]. Any unethical behaviour as a professional will lead to distrust of patients and a sense of insecurity which in turn reduces the progress in the patient condition that will lead to ending up of the professional's career [6]. This is the reason why any sought of unprofessional behaviour has to reported and stopped immediately.Since ethical acceptance begins at the college level[7], it is important to know level of ethical knowledge and their willingness to follow ethics and their ability to make decisions in critical cases and their willingness to report the unethical behaviour that is either conducted by their superior or their colleague.Though this subject is of high importance there are not enough researches done in India to find out about the ethical dilemmas and decision making related to physiotherapy. Our study aims to find out how well the students are able to understand the seriousness of the misconduct of the therapist to the patient and how willing are they to expose any misconduct they encounter to the internal or external environment. Internal disclosure implies reporting misconduct to an higher authority within the organization. External disclosure implies reporting misconduct outside the organization such as law enforcement or media

Materials and Methodology

Based on the selection criteria only physiotherapy students of UG final year, PG first and second year and interns those who were pursuing their degree in Chennai were selected as participants. Departmental ethical committee approval was obtained. A total of 100 participants were aimed and a closed ended questionnaire was sent as google forms. Students from colleges without ethics as a part of curriculum were excluded. Initially the participants were asked to fill the demographic data that included the name, age, college they belonged to, and the year they were studying. The questionnaire consisted of 2 clinical scenarios and 5 set of questions were asked under each scenario. The first scenario was related to colleague's misconduct and the second one was concerned with the misconduct by the higher official. The first question dealt with how far the students were able to understand the seriousness of the situation while the second question dealt with the student's willingness to confront the misbehaviour to the one who committed it and insisting him to correct what he did. Question 3 and 4 dealt with blowing whistle to the internal environment. Question 5 is related to the blowing of whistle to the external environment. All the questions were rated according to 5-point likert scale. The answer for the first question ranged from "very serious" to "not serious at all". The answers for the remaining four questions ranged from "strongly agree" to "strongly disagree".

Results

The mean differences between the groups were assessed using the paired sample's test. The data were analyzed using SPSS statistical software, PC version 20.0

Table 1: Comparison between the respondents' scores for the two case stories regarding the severity of the misconduct, the likelihood of taking action to change the situation and the indices of internal and external whistle blowing.

	Sample	Case story 1 colleague misconduct (n 100)		Case story 2 director misconduct (n 100)	
		Mean	SD	Mean	SD
1. Severity of the misconduct	100	3.75	0.989	4.03	0.915
2. Likelihood of taking action by confronting the person responsible for the wrongdoing to repair the harm done	100	3.84	0.861	4.04	0953
3. Internal whistle blowing: likelihood of reporting the misconduct to someone in the workplace	100	3.51	1.010	3.78	1.069
4. External whistle blowing: likelihood of reporting the misconduct to the Physical Therapists' Association	100	3.43	1.037	3.64	0.802
5. External whistle blowing: likelihood of reporting the misconduct to the media	100	3.15	1.086	3.65	1.029

Table 1 shows the comparison between the respondents' scores for the two case stories regarding the severity of the misconduct, the likelihood of taking action to change the situation and the indices of internal and external whistle blowing.

Table 2: Paired sample test

Paired Samples Statistics					
		Mean	**N**	**Std. Deviation**	**Sig.**
Pair 1: Internal whistle blowing reporting to a superior in the work place	If you decide not to talk to your colleague, or if you have talked to her about the matter and not succeeded in getting her to report the incident, how likely is it that you will go to someone at the center who has the power to intervene, such as the head of physiotherapy ward or ethics comitee,or if snyone is at the rehablitationcentre	3.51	100	1.010	.010
	If you decide not to talk to the director, or if you have talked to her and not been able to change her mind, how likely is it that you will report the directorâ€™s intentions to someone at the center who has the power to intervene, such as the centerâ€™ s genral director or ethics comitee if any one is at the centre	3.78	100	1.069	
Pair 2: External whistle blowing reporting to the physical therapists association	If you decide not to approach anyone at the centre, or if you do talk to someone and he or she does nothing to intervene, how likely is it that you will turn to the Physical Therapists' Association, an external body	3.43	100	1.037	
	If you do not refer the matter to an authority at the centre, or if you do and he or she does not intervene in the director's decision, how likely is it that you will turn to the Physical Therapists' Association, an external authority?	3.64	100	0.802	.016
Colleague's report to media	If you decide not to report the matter to the Physical Therapistsâ€™ Association, or if you do talk to them and they do nothing, how likely is it that you will report the matter to the media?	3.15	100	1.086	.056
Pair 3: Director report to media	If you decide not to report the matter to the Physical Therapists Association, or if you do talk to them and they do nothing, how likely is it that you will report the matter to the media?	3.65	100	1.029	

Table 1 shows the comparison between the respondents' scores for the two case stories regarding the severity of the misconduct, the likelihood of taking action to change the situation and the indices of internal and external whistle blowing. From the scores obtained, the likelihood of reporting director's misconduct is higher than that of colleague's misconduct.

Table 2 shows the comparison between the scores of the internal and external whistle blowing to the association and to media. From the scores obtained, the likelihood for internal whistle blowing is higher than that of external whistle blowing. There is a significant difference (0.010) between the internal whistle blowing for colleague and director misconduct. There is a significant difference (0.016) between the external whistle blowing for colleague and director misconduct in reporting to the physical therapy association. There is a non-significant difference (0.056) between the external whistle blowing for colleague and director misconduct in reporting to the media.

Discussion

The purpose of this study is to find out how well the students are able to understand the seriousness of the misconduct of the therapist to the patient and how willing are they to expose any misconduct they encounter to the internal or external environment. Totally 100 physiotherapy students with ethics as a part of curriculum were taken into consideration out of which 58 female and 42 male students have participated. From the study it is found that the physiotherapy students witnessed the situations that are harmful to the patients to be very serious. In such situations, they are likely to report to the higher authorities in both cases

of misconduct by their colleague as well as manager. However the rate of likelihood to report varied between both the case stories. Hence there was a significant difference obtained by the statistical analysis of the obtained data. From the scores obtained the likelihood of considering the severity of misconduct, confronting the person responsible for the wrongdoing, reporting the misconduct to someone in workplace, to the association or to the media for the director's misconduct was higher than that of colleague's misconduct. This shows that the students give more importance to the interest of patient rather than supporting the misconduct of colleague or manager. In situations where such misconduct arises their willingness to report seems to be expressed rather than supporting the misconduct. Similarly the scores obtained for internal whistle blowing was higher than that of external whistle blowing. The reason for this might be because the students prioritize to report to the superior authority within the organization than disclosing it outside the organization[8]. Also **Abraham Mansbach et al., (2011)** has stated that the students prefers and follows a pattern of internal whistle blowing after which the external whistle blowing is being is approached rarely[9]. **Anna Myers., (2008)** has also stated that it is wiser to whistle blow first internally and then externally outside the organization. It is more ethical and also being loyal to the organization[10]. While also expresses that whistle blowing to an unethical or a deviant act is a core component of an employee and that at all costs whistle blowing to root out a criminal activity which is possibly harmful to the client or the reputation of the institution must be encouraged[11].

Conclusion

Ethics being a part of Physiotherapy curriculum, these students have well understood the ethical and professional behavior and have good ethical acceptance. Hence we conclude that the students do understand the seriousness of any misconduct of a therapist to the patient and are willing to expose any misconduct they encounter to the internal or external environment.

The limitation and recommendation of the study are The answer that was recorded by the participants was just their interest and opinion towards whistle blowing as a student. But the actual response that they give when they are into the situations might vary. In future studies can be done with a comparison between physiotherapy students with and without ethics as a part of curriculum. In future studies can be done with a comparison between physiotherapy students and practitioners.

Ethical Clearance: Departmental Ethical clearance was obtained.

Effect of Phase 1 Cardiac Rehabilitation to Non-Invasive Hemodynamics in Acute Myocardial Infarction Patients

Desi Natalia Trijayanti Idris[1], Dian Taviyanda[1], Srinalesti Mahanani[1]

[1]Lecturer of Nursing Study Bachelor Program, STIKES RS Baptis Kediri

Abstract

Cardiovascular emergencies often occur suddenly, delays in treatment cause the condition to worsen. One of the cases of cardiovascular emergency is acute myocardial infarction (AMI). AMI patients must have stable hemodynamics in order to improve their condition. Management of nursing care that can be done to maintain hemodynamic stability of AMI patients is the implementation of Phase 1 Cardiac Rehabilitation. The purpose of this study was to analyze the effect of Phase 1 Cardiac Rehabilitation on Non-Invasive Hemodynamics for Acute Myocardial Infarction Patients in the ICCU Room of Kediri Baptis Hospital. The research design used a quasy experiment one group pre post test design. Population in this study were all AMI patients who were treated in the ICCU Room of the Kediri Baptist Hospital who were taken using a quota sampling technique with a sample size of 35 respondents. The instrument used was an observation sheet including: systolic - diastolic blood pressure and heart rate. Phase 1 cardiac rehabilitation program intervention was carried out for 2 consecutive days, with 2 training sessions/day (morning and evening). Each training session with a duration of 15 minutes. The data analysis of this study used the Paried T-Test statistical test. The results of this study showed that p = 0.026, p = 0.014 p <0.05 and that p = 0.024 p <0.05, which means there is an effect of phase 1 cardiac rehabilitation on cytolic, diastolic blood pressure and heart rate in acute myocardial infarction patients in the ICCU room of Kediri Baptist Hospital. Conclusion Cardiac Rehabilitation Phase 1 has a significant effect on heart muscle function based on the results of blood pressure checks seen from systolic and diastolic and heart rate. Where the greatest significance is on heart rate compared to blood pressure.

Keywords: *Cardiac Rehabilitation Phase 1, Non-Invasive Hemodynamics, Blood Pressure, Heart Rate.*

Introduction

Acute Myocardial Infarction (hereinafter referred to as AMI) is myocardial necrosis caused by an imbalance between the supply and demand for oxygen to the heart muscle[1] and or AMI is a disease that attacks the heart organ. Which causes cell death in the heart muscle due to a long myocardial ischemic process in the heart[2]. Patients with AMI must receive therapy for at least 24 hours, and preferably for the index hospitalization duration, up to 8 days or until the patient does not feel the symptoms of infarction, namely no chest[3]. Myocardial ischemia will occur in the initial state if reperfusion action is not taken immediately, this can lead to permanent (irrevesible) heart necrosis. AMI can cause complications due to ventricular remodeling and ultimately can lead to cardiogenic shock, congestive heart failure, and persistent ventricular dysrhythmias. Management of action on AMI cannot be delayed if there is a delay every 30 minutes it can increase the risk of death by about 80%[4]. During treatment it is necessary to observe to see whether the patient's hemodynamics have increased or decreased. It is hoped that the hemodynamic condition after an AMI attack can be maintained at normal levels/ conditions.

Based on data from the American Heart Association in 2014, heart disease is the cause of 1 in every 6 deaths in the United States in 2010[5]. Heart disease causes 7.2 million deaths per year worldwide[6]. AMI and its associated functional disorders can cause heart failure affecting 2-3% of the population in industrialized countries with an increase in age> 65 yr. A combined estimate of 20 million people have heart failure in Europe and the US and its prevalence is increasing. The highest Case Fatality Rate (CFR) occurred in AMI (13.49%) and

then followed by heart failure (13.42%) and other heart diseases (13.37%)[7]. This phenomenon is supported by the results of the Basic Health Research in 2013 which showed that AMI is one of the diseases diagnosed by many doctors compared to other heart disorders[8]. According to the medical record data of the ICCU room at Kediri Baptist Hospital (November 2019), 45 patients came with an AMI medical diagnosis.

AMI patients experience atherosclerotic plaque in the blood vessels, this can play an important role in the occurrence of total or almost total occlusion, either due to the thrombus blockage that is formed or by platelet aggregation and inflammatory responses that can cause a decrease in coronary blood flow, this results in failure of contractions ventricles, decreased cardiac output (hemodynamically unstable) and compensatory mechanisms that will overwork the heart and can cause the area of necrosis to expand[9]. Increased heart rate rhythm usually does not occur continuously, parasympathetic stimulation (mostly inferior) can reduce heart rate and blood pressure[10]. Blood pressure has an important role in determining risk stratification and effective prognosis information, where low blood pressure is associated with a poor prognosis, although there are several studies reporting different results[11]. Hemodynamic treatment in AMII patients aims to improve oxygen delivery in the body which is affected by (Cardiac Output/CO), hemoglobin (Hb), and oxygen saturation (SaO2). If oxygen delivery is impaired due to decreased cardiac output (CO), proper handling is required, cardiac output is an important hemodynamic variable and is often assessed by one of them based on NIBP and on the calculation of the MAP value (Mean Aeterial Presure), by measuring pressure. Blood and mean arterial pressure (MAP), can indicate conditions of cardiac output.

AMI management requires a holistic approach, both in prevention and treatment. The management of AMI can be divided into two, namely pharmacology and non pharmacology. In general, the pharmacology that can be done is to give nitroglycerin tablets if pain complaints persist, aspirin, Clopidogrel, morphine sulfate, and reperfusion therapy. For AMI patients, the principle of pharmacological management is to make a prompt and precise diagnosis, determine whether there is an indication for immediate reperfusion with thrombolytics, restore coronary blood flow with primary thrombolytics to save the heart from AMI, limit the extent of AMI, and maintain heart function[12]. Research that supports this Patrick, (2013) states that AMI patients undergo reperfusion with fibrinolytic therapy for at least 48 hours, and preferably for the duration of hospitalization index, up to 8 days or until the patient does not feel the symptoms of infarction, which is not feeling chest pain[3]. Non-pharmacological management can be provided with bed rest, oxygenation, and cardiac rehabilitation[13]. In addition to fibrinolytic therapy, post AMI patients need to be rehabilitated by the heart, so that they can return to optimal conditions physically, medically, psychologically, socially, emotionally, sexually, and vocational, cardiac rehabilitation is also useful for exercising mobility and heart work and restoring conditions to meet needs everyday life. It is possible that if cardiac rehabilitation is not carried out then the heart muscles periodically decrease activity, expand ischemia or infarction and trigger repeated attacks, this can lead to death. The rehabilitation program for people with heart problems is a multiphase program designed to restore heart problems, especially those with coronary artery disorders. This program includes physical activity training, psychological counseling, and behavioral therapy towards a healthy lifestyle[14]. This program aims to optimize heart function, eliminate psychological problems, and improve the quality of life of patients[15]. Rehabilitation is an integral part of the holistic management of heart disease, in addition to standard medical therapy and cardiac intervention measures for some sufferers. Cardiac rehabilitation is basically a process that aims to restore the physical, psychological, and social functions of an AMI patient to an optimal level. This is supported by research[16] which explains that when cardiac rehabilitation is carried out there needs to be a doctor's control as the person in charge of care and it is necessary to observe vital signs and evaluate heart records. Cardiac rehabilitation is carried out by doctors, physiotherapists, nurses, psychologists, nutritionists and social workers. The cardiac rehabilitation program consists of four phases, namely phase I during which the patient is hospitalized which focuses on early ambulation and health education. Phase I cardiac rehabilitation is the initial recovery after an acute phase attack carried out in the ICCU room for 2-3 days, in infarct patients without complications, and 5-7 days in infarct patients who have complications. Phase II immediately after the patient is discharged from the hospital which is carried out under the supervision of the rehabilitation team. Phase III immediately after phase II is still under supervision and phase IV is a long-term maintenance phase. The goal of rehabilitation in phase

I is to accelerate the recovery process and minimize the risk of prolonged rest and immobilization, such as deep vein thrombosis and muscle weakness[17].

Method

The research design used a quasy experiment one group pre post test design. The single research variable is non-invasive hemodynamics, namely blood pressure and pulse frequency. Population in this study were all AMI patients who were treated in the ICCU Room of the Kediri Baptist Hospital who were taken using a quota sampling technique with a sample size of 35 respondents. The action that will be given to the patient is cardiac rehabilitation phase 1 which is performed 1x24 hours after the patient does not feel chest pain. Prior to the implementation of phase 1 cardiac rehabilitation, the patient was measured blood pressure and pulse frequency as measured variables. Researchers were assisted by assistants or research assistants (ICCU room nurses) to select predetermined respondents and then provided informed consent and explanations of research procedures. The instrument used was an observation sheet including: systolic - diastolic blood pressure and pulse frequency. Hemodynamic monitors are used to measure the patient's blood pressure, pulse rate. Phase 1 cardiac rehabilitation program intervention was carried out for 2 consecutive days, with 2 training sessions/ day (morning and evening). Each training session with a duration of 15 minutes. Hemodynamic assessment was done pre-test (before intervention), and post-test every day after the intervention in the afternoon. The data in the study consist of two demographic data and respondent hemodynamic data. The data analysis of this study used the Paried T-Test statistical test. Before the statistical test was carried out, the data normality was tested and declared normal. The study was conducted after obtaining ethical clearance from the Health Research Ethics Commission (KEPK) STIKES Baptis Hospital Kediri. This research has passed ethics with letter number 076/30/III/EC/KEPK-3/STRIKES WSBK/2020.

Result

Description of Sample Characteristics: Characteristics of acute myocardial infarction patients based on gender with the most frequent male 21 respondents, namely 60%, age with a maximum frequency of 56-60 years 21 respondents, namely 34.3%, with a mean of 60.00 and a standard deviation of ± 7.985, a history of hypertension with a frequency of more than 50% had a history of hypertension 20 respondents that is 57.1%, a history of diabetes mellitus with a frequency of more than 50% had a history of hypertension 19 respondents that is 54.3% and family history with the frequency of AMI at most have a family history with AMI 24 respondents that is 68.6%.

Non-Invasive Hemodynamic Data (Blood Pressure and Heart Rate):

Table 1. Statistical Test of the Effect of Phase 1 Cardiac Rehabilitation on Systolic Blood Pressure in Acute Myocardial Infarction Patients in the ICCU Room at Kediri Baptis Hospital April - August 2020 (n = 35)

		t	df	Sig. (2-tailed)
Pair 1	Difference in systole before intervention - difference in systole after intervention	2.333	34	.026

Table 2. Statistical Test of the Effect of Phase 1 Cardiac Rehabilitation on Diastolic Blood Pressure in Acute Myocardial Infarction Patients in the ICCU Room at Kediri Baptis Hospital April - August 2020 (n = 35

		t	df	Sig. (2-tailed)
Pair 1	Difference of Diastole Before Intervention - Difference of Diastole After Intervention	2.590	34	.014

Table 3. Statistical Test of the Effect of Phase 1 Cardiac Rehabilitation on Heart Rate in Acute Myocardial Infarction Patients in the ICCU Room at Kediri Baptist Hospital April - August 2020 (n = 35)

		t	df	Sig. (2-tailed)
Pair 1	Difference of Diastole Before Intervention - Difference of Diastole After Intervention	2.363	34	.024

Based on table 1, the results show that p = 0.026 p <0.05. Based on table 2, the results show that p = 0.014 p <0.05 and based on table 3, the results show that p = 0.024 p <0.05, which means that there is an effect of phase 1 cardiac rehabilitation on cytolic, diastolic blood pressure and heart in acute myocardial infarction patients in ICCU room Kediri Baptist Hospital.

Discussion

Mortality and morbidity of cases of cardiovascular emergencies often occur suddenly, delays in handling brought to the emergency room cause the condition to worsen. Cardiovascular disease is a disease that involves the heart and blood vessels. Heart disease is estimated to be the leading cause of death worldwide, this is evidenced by the rapidly increasing prevalence of cardiovascular disease in developed and developing countries. The prevalence and incidence of this disease is quite high and is increasing from year to year[18].

Heart problems are health problems whose incidence has increased from year to year. One of the heart disorders is Acute Myocardial Infarction (AMI). Globally, this is the first major cause of death in developing countries, replacing the death rate due to infection, another thing stated by Waly et al (2014) is that one of the cardiovascular diseases that is the leading cause of death in the world is Acute Myocardial Infarction (AMI). The case fatality rate (CFR) of the IMA is the highest compared to other heart diseases. Intensive systematic efforts are needed to prevent increased morbidity cases that can be handled by cardiac rehabilitation programs. Patients with heart problems need a comprehensive rehabilitative program to develop post-attack physical abilities and prevent recurrent attacks. Heart disorders are pathological conditions in the heart where there are abnormalities that cause physiological disorders of the heart.

IMA is a condition in which the blood supply to a part of the heart stops so that the heart muscle cells die[19]. This situation refers to the process of damage to the myocardial tissue of the heart which experiences necrosis due to inadequate blood supply so that coronary blood flow is reduced. The cause of decreased blood supply may be due to critical narrowing of the coronary arteries due to atherosclerosis or total blockage of the arteries by embolism or thrombus. Therefore, in each case there is always an imbalance between the supply and demand for cardiac oxygen[20].

This disorder can be asymptomatic (asymptomatic), mild, to severe. Heart attack (myocardial infarction) is a serious disorder in which heart blood flow stops, causing the death of some heart cells. Heart problems are the number one cause of death in adults in developed countries. The factors that trigger a heart attack are smoking, consuming high cholesterol foods, lack of movement, and laziness to exercise, stress, and lack of rest[21]. In coronary heart disorders, there are variations in the level of atherosclerosis, the degree of myocardial ischemia, impaired heart ventricular function, the frequency and degree of heart symptoms such as dysrhythmias, increased blood pressure and heart rate response to exercise and fatigue[22]. These conditions need to be evaluated to estimate the risk of further infarction, cardiac arrest and heart failure. The clinical judgment regarding the exercise program, type and type of exercise is mainly based on the calculation of the risk (prognosis) and the functional capacity of the patient.

Hemodynamic treatment in AMI patients aims to improve oxygen delivery in the body which is affected by (Cardiac Output/CO), hemoglobin (Hb), and oxygen saturation (SaO2). If oxygen delivery is impaired due to decreased cardiac output (CO), proper handling is needed, cardiac output is an important hemodynamic variable and is often assessed by one of which is based on NIBP and on the calculation of MAP (Mean AeterialPresure), by measuring pressure. Blood and mean arterial pressure (MAP), can indicate conditions of cardiac output. Hemodynamics is divided into 2, namely invasive and non-invasive. No invasive hemodynamics consists of indicators as a measure. Two of them are blood pressure and pulse rate. High and persistent blood pressure will cause direct trauma to the walls of the coronary arteries, thereby facilitating coronary atherosclerosis. This causes angina pectoris, coronary insufficiency and myocardial infarction to occur more frequently in people with hypertension than normal people[23]. High blood pressure is a risk factor for AMI. Patients with high blood pressure experience an increase in after load which indirectly increases the workload of the heart. Conditions like this will trigger left ventricular hypertrophy as compensation for increased after load which ultimately increases the heart's oxygen demand. (AMI) can occur repeatedly, this recurrent myocardial infarction is called recurrent acute myocardial infarction because of uncontrolled risk factors or patient non-compliance in undergoing rehabilitation therapy. Patients who have experienced an AMI attack are 50%

likely to experience a recurrent[24]. Recurrent AMI can be prevented by controlling risk factors. Several studies have shown that secondary prevention, including risk factor control and pharmacological treatment, can prevent the incidence of recurrent acute myocardial infarction and reduce mortality and morbidity in patients with coronary heart disease[25]. Secondary prevention by controlling one of them by controlling blood pressure. Secondary prevention is based on clinical evidence and studies using control, large numbers of samples[26-27].

Current medical treatment for AMI patients is generally carried out with pharmacological therapy and cardiac revascularization[28]. Revascularization measures that have been well proven in patients with AMI caused by atherosclerosis are CABG (Coronary Artery Bypass Graft) surgery and PCI (Percutaneous Coronary Intervention) procedures. AMI patients who have undergone cardiac revascularization will undergo further action, namely cardiac rehabilitation. The rehabilitation program for people with heart problems is a multi-phase program designed to treat heart problems, especially those with coronary artery disorders. In this program, patients are trained to return to life optimally and productively. This program is based on physiological, psychological, social, vocational and recreational knowledge. This program includes exercise therapy, psychological counseling, and behavioral therapy towards a healthy lifestyle. Lifestyle suggestions include quitting smoking, a diet high in fiber, low in fat and stress management.

The rehabilitation program for AMI patients aims to: (1) optimize the physical capacity of the body, (2) provide counseling to patients and families in preventing worsening and (3) help patients to return to physical activities such as before experiencing heart problems[29]. The physical exercise program is based on the patient's level of awareness and indindual ground. The important thing to note is that the exercise program should be monitored based on the target pulse frequency. In addition, the rehabilitative physical exercise program for people with heart problems aims to optimize the physical capacity of the body, provide counseling to patients and their families in preventing worsening and helping patients to return to activities' physical as before experiencing heart problems[15]. States those contemporary training programs are directed based on individual needs. In low-risk individuals, an unsupervised exercise program can be carried out immediately, whereas in high-risk patients, a monitored exercise program can be carried out over a longer time interval. In general, the training program is divided into inpatient and outpatient programs[21].

Inpatient training program can be carried out from 48 hours after heart trouble as long as there are no contraindications. Physical exercise is limited to daily activities, such as hand and leg movements and changing postures. The exercise program usually takes the form of supervised ambnulatory physical therapy. In this phase, ECG monitoring is necessary to assess the response to exercise. Training in this phase must be according to the readiness of the team that can handle an emergency situation if a heart attack occurs during training. The benefits of physical exercise in this phase are as additional surveillance material, train patients to be able to carry out activities in daily activities, and to avoid negative physiological and psychological effects on bedrest. The goals of this first phase of physical exercise must be tailored to the patient's needs. Patients with low activity may only need physical exercise to support daily activities (ADL: activity of daily life). Patients with better physical capacity can run an exercise program for tertiary prevention and follow a long-term program to increase cardiorespiratory endurance, body composition, and flexibility and muscle endurance[30].

AMI patients need heart rehabilitation, so that they can return to an optimal condition physically, medically, psychologically, socially, emotionally, sexually, and vocally, cardiac rehabilitation is also useful for exercising mobility and heart work and restoring conditions to meet the needs of daily life. . If no cardiac rehabilitation is done, the heart muscles periodically decrease activity, expand ischemia or infarction and trigger repeated attacks, this can lead to death. The physical exercise program is based on the patient's level of awareness and individual needs. The important thing to note is that the exercise program should be monitored based on target pulse frequency, perceived exertion and prediction of METs. If there are symptoms of cardiac, orthopedic or neuromuscular disorders, it is necessary to review the exercise program[31]. Patients with heart disease can return to being productive people in their environment so that a new approach is needed as an additional method that can improve the care for people with "coronary prone", patients after myocardial infarction, and sufferers after coronary bypass surgery. This additional treatment program is known as "Cardiac Rehabilitation". This is of course very much in accordance with the National Health System (SKN) which states that health efforts must

cover promotive, preventive, curative and rehabilitative aspects.

The cardiac rehabilitation program is one of the non-pharmacological management of AMI patients. AMI patients are the main indication that a cardiac rehabilitation program is recommended[32]. Deaner further explained that the cardiac rehabilitation program consists of four phases, namely phase I while the patient is in the hospital, phase II immediately after the patient is discharged from the hospital, phase III immediately after phase II is still under the supervision of the cardiac rehabilitation team, and phase IV is the term maintenance phase long. The rehabilitation program for AMI patients aims to restore the optimal physical, mental, social and vocational conditions.

AMI can indeed cause immobilization and instability of hemodynamics, however, so that patients avoid various complications due to immobilization and hemodynamic instability, it is still necessary to do cardiac rehabilitation where cardiac rehabilitation is done in phase 1 because it is done after the patient does not feel pain. Phase 1 cardiac rehabilitation should be given immediately in order to train the range of motion of the joints, change position exercises (tilt, sit, and stand), muscle strengthening exercises, static balance exercises either sitting or standing. All exercises are carried out in stages, according to the patient's condition. Cardiac rehabilitation in critical patients can increase muscle strength, reduce oxidative stress and inflammation, during activity or exercise will maximize 60% -75% oxygen intake and increase antioxidant production[33]. The cardiac rehabilitation program currently developed by nurses can improve not only physical and cardiac outcomes, but also mental and psychological well-being before discharge from the hospital[34].

Phase 1 cardiac rehabilitation therapy is very beneficial for AMI patients, however the implementation of cardiac rehabilitation by nurses must be based on the patient's level of awareness and individual needs. In addition, the important thing for nurses to pay attention to is that the cardiac rehabilitation program should be monitored based on blood pressure targets and perceived exertion[35]. This is very necessary to optimize the health status of AMI patients. The results of previous research conducted by[36] proved that the cardiac rehabilitation program, one of which is early mobilization, can reduce heart rate and does not cause changes in blood pressure. Therefore, based on the results of this study, the use of a cardiac rehabilitation program, namely early mobilization in the care of AMI patients, is highly recommended. The impact if hemodynamics is not monitored carefully during early mobilization will result in deterioration, shock and loss of consciousness. Early mobilization will increase the work of the heart, the body tolerates it quickly. Therefore monitoring is very necessary during early mobilization interventions to prevent worse conditions. Critically ill patients generally have poor vascular elasticity, malfunctioning feedback cycles and/or low cardiovascular reserves. For patients whose hemodynamic status is imbalanced, a solution that can be suggested is to train the patient to tolerate changes in position rather than leaving them in a supine position[37]. Hemodynamic instability is one of the challenges for nurses to mobilize critical patients. To balance the risks and benefits of mobilization in critical patients, nurses must determine the right type of mobilization, pay attention to certain diseases, assess risk factors, determine the time for mobilization sessions, and reduce the speed of mobilization that can affect the cardiovascular system response[37].

The results showed that there was an effect of phase 1 cardiac rehabilitation on systolic and diastolic blood pressure. Cardiac rehabilitation phase 1 has a significant association with changes in heart muscle function (seen from blood pressure). This can be seen from the paried T-Test where the p-value is 0.026, 0.014 ($p < 0.05$), meaning that there is a significant effect between phase 1 cardiac rehabilitation on blood pressure. This can also be explained by the extent of changes that occurred in patients with AMI before phase 1 cardiac rehabilitation intervention and after being given phase 1 cardiac rehabilitation. According to WHO (2000), the diastolic filling cardiac cycle is determined by the effective filling pressure and resistance in the wall. The ventricular muscles (preload), while the ability of systolic ejection depends on the strength of the contraction of the heart muscles (myocardium) against blood pressure (afterload). Phase 1 cardiac rehabilitation can affect blood pressure due to the efficiency of the work of the heart or the ability of the heart to increase according to the changes that occur. Changes that occur can be in the form of heart rate, stroke volume, and cardiac output. When performing phase 1 cardiac rehabilitation, blood pressure will rise considerably, systolic blood pressure can rise to 150 - 200 mmHg from resting systolic pressure of 110-120 mmHg. Conversely, as soon as the physical exercise is finished, the blood pressure will drop below

normal and lasts for 30 - 120 minutes. Regular phase 1 cardiac rehabilitation can lower blood pressure. The recommended frequency of phase 1 cardiac rehabilitation is 3-5 times a week, with duration of 15-60 minutes of exercise once. Changes in blood pressure, among others, occur because the blood vessels are dilated and relaxed (relaxes the blood vessels) as well as widening a water pipe will reduce water pressure. In this case, exercise can reduce peripheral resistance. Changes in blood pressure can also occur due to reduced pumping activity of the heart. The heart muscle in people who regularly exercise is very strong, so the heart muscle is also strong, 12 weeks of programmed physical exercise is more likely to cause significant changes in the work efficiency of the heart compared to peripheral resistance. The results of this study are supported by research conducted by[38] which states that there is a significant effect on blood pressure with a p-value of 0.001 ($p < 0.05$), other studies that support[39] stated that the cardiac rehabilitation program was effective in encouraging an initial increase in exercise capacity and a significant reduction in resting systolic and diastolic blood pressure ($p < 0.001$) and research that[40] stated that phase 1 cardiac rehabilitation had an effect on hemodynamic status (blood pressure: Systole, diastole) $p < 0.005$.

The results showed that there was an effect of phase 1 cardiac rehabilitation on the pulse rate (heart rate). Cardiac rehabilitation phase 1 has a significant association with changes in heart muscle function (seen from and pulse rate). This can be seen from the paried T-Test where the p-value is 0.014 ($p < 0.05$), meaning that there is a significant effect between phase 1 cardiac rehabilitation on pulse frequency. The heart rate is produced by the contraction of the heart muscle as it pumps blood. A normal heart rate has a contraction period of 0.40 from the cardiac cycle. Cardiovascular regulation is seen immediately after exercise. This work also serves to transport the O2 needed by the muscles to contract during exercise. When the heart is at rest, the pulse will be less. The normal pulse rate is 60-80 beats per minute. O2 consumption by the heart muscle can be calculated by multiplying the pulse rate and systolic blood pressure. Trained cardiac muscle requires less O2 for any given load and requires less O2 for physical work or activity. Cardiac Rehabilitation Phase 1 is a good form of exercise for cardiorespiratory fitness. The increase in pulse rate during activity should be between 70-75% of the maximum pulse rate. Meanwhile, the maximum pulse rate is 220 as an absolute number minus age. Cardiac rehabilitation in myocardial infarction must be started immediately after the patient is stable and continued for life[41]. Heart rehabilitation phase 1 is highly recommended in influencing and improving the work of the heart[42]. From the above explanation, it can be concluded that the phase of Cardiac Rehabilitation affects the pulse of a patient with AMI, because in principle, every increase in one's activity will be followed by an increase in pulse, because increased activity requires body metabolism. Thus, to meet these metabolic needs, high oxygen is needed as well, this need will be met by increasing the heart rate to pump blood throughout the body that needs it. This study is supported by research conducted by[40]which states that phase 1 cardiac rehabilitation has an effect on hemodynamic status (pulse frequency) $p < 0.005$. Another supportive study is[43] which states that a cardiac rehabilitation program can help increase pulse frequency with a value of $p = 0.040$. In addition, the results of this study are also supported by the research of[39] stating that after rehabilitation, the case group showed a significant increase in the rehabilitation time of the heart in phase 1 heart rate ($p < 0.001$). There are also studies that have different results from this study, namely research that has been conducted by[38] states that there is a significant effect on blood pressure with a pvalue of 0.001 ($p < 0.05$). Phase 1 cardiac rehabilitation has no significant effect significant changes to the respondent's heart rate.

Conclusion

Cardiac Rehabilitation Phase 1 has a significant effect on heart muscle function based on the results of blood pressure checks seen from systolic and diastolic and heart rate. Where the greatest significance is on heart rate compared to blood pressure.

Awareness among MBBS Students About Rise of Violence Against Doctors

Divya Reddy Pannala[1], S.M. Krishna Sagar[2], Hemantha Rao Amara[3], Harshini Deshapathi[4]

[1]Assistant Professor, Department of Forensic Medicine RVM Institute of Medical Sciences, Siddipet, [2]Assistant Professor, Department of Forensic Medicine, Mahavir Institute of Medical Sciences, Vikarabad, [3]Professor, Department of Forensic Medicine, [4nd] Year UG, RVM Institute of Medical Sciences, Siddipet

Abstract

World Health Organisation defined workplace violence as incidents where employees are abused, threatened, assaulted or subjected to other offensive behaviour in circumstances related to their work. According to an ongoing study by the Indian Medical Association, over 75% of doctors have faced violence at work, majority of the cases were reported from emergency wards and Intensive Care Units. In the last decade, Governments of 19 states in India have passed laws for the protection of physicians. However, the law is not being effectively implemented either due to lack of awareness or resistance from administration. A questionnaire based study was conducted on MBBS students to assess their level of awareness about violence on doctors and protection laws. The knowledge among the students about these laws was very low, which could be improved if the topic "Violence on Doctors" is included in the new competency based curriculum, separately in Forensic Medicine subject.

Keywords: *Awareness, violence, MBBS students, protective laws, competency based curriculum, doctors.*

Introduction

According to World Health Organisation, healthcare workers are four times more likely to be injured due to workplace violence than all other workers combined.[1] This problem is mainly due to lack of social awareness, poor infrastructure in many hospitals and increasing expectations even during poor prognostic conditions leading to rise in acts of violence against doctors. Hence, it has become necessary to raise awareness regarding this issue and implement stringent regulatory measures to prevent such kind of violent acts.

In a study conducted by Indian Medical Association, over 75% of doctors across the country have faced at least some form of violence and in that, 68.33% of the violence was committed by the patient attenders or escorts.[2] But these numbers are underestimated, as most cases of violence are not reported especially in India. In the last decade, Governments of 19 states in India have passed laws for the safeguard of physicians.[3] However, the law is not being effectively implemented either due to lack of awareness or resistance from administration.

To avoid any serious problems due to violence, a doctor must be well trained in dealing with such incidents. The knowledge on national and state protective laws against violence on doctors is important and they must be included as a part of the teaching curriculum at undergraduate level which would help the upcoming doctors to know about their legal rights. Thus, the current study aims to evaluate the level of awareness about rise in violence against doctors and protection laws amongst the MBBS undergraduates.

Methodology

This was a cross sectional study done over a period of 2 months from 1st May to 30th June 2020.

Questionnaire (dichotomous and multiple-choice questionnaire) was distributed through online survey (google forms) to students of all medical colleges in the states of Telangana and Andhra Pradesh. Based on the completion of the forms within the given study period, 405 MBBS undergraduate students belonging to three academic years (2nd, 3rd and 4th year MBBS) were a part of this study. The data were analysed in SPPS and expressed as number and percentages and presented in the form of text, tables, and figures.

Results

Table 1: Awareness on violence

Variables		Frequency	%
On rise in incidents	Yes	404	99.8
	No	1	0.2
Components of Violence	All components	315	77.8
	Combination of more than 2 components	70	17.3
	Single Component	13	3.2
	None	2	0.5
Mode of awareness	Media	371	91.6
	Family	2	0.5
	Friends/Colleagues	27	6.7
	Teachers/Professors in College	5	1.2
Most recent incident you have heard of/seen/experienced by yourself	Assaults in Telangana state	377	93
	Assaults in AP state	8	2
	Assaults in other states	10	2.5
	Could not recall	10	2.5

315 (77.8%) students mentioned that physical assault, psychological violence including verbal abuse, telephonic threats and warning gestures, damage to medical equipment and damage to clinical establishment constitute as violence on doctors. 12 (3%) students considered violence as only physical assault, 1 (0.2%) as only verbal abuse, 5 (1.2%) of them it a combination of physical and verbal abuse. 70 (17.3%) considered it to be a varying combination of the components. 2 (0.5%) participants did not consider any of the components as violence on doctors.

Table 2: Awareness on laws and punishments protecting doctors

Variables		Frequency	%
Awareness of any National and State Laws protecting doctors	Yes	166	41
	No	239	59
Special judicial Punishments	Yes	188	46.4
	No	217	53.6
If punishments for Hurt or Grievous Hurt (as per IPC) would be applicable for miscreants	Yes	201	49.6
	No	16	4
	Don' Know	188	46.4
If punishments are different for assault on doctors from assault on other health care providers (nurses/paramedical staff)?	Yes	125	30.9
	No	280	69.1

356 (87.9%) of the participants said that the existing laws are not sufficient for protecting doctors whereas 7 (1.7%) of them think they are and 42 (10.4%) do not know the answer to the question posed. 345 (85.2%) of the students mentioned that punishments should vary based on the type and severity of violence and 60 (14.8%) do not consider so.

Table 3: Method to increase awareness

Variables		Frequency	%
Conducting workshops and CME programs	Yes	366	90.4
	No	39	9.6
Participation of student unions for public awareness	Yes	401	99
	No	04	1
Topic inclusion in Forensic Medicine under new Competency Based Curriculum	Yes	393	97
	No	12	3

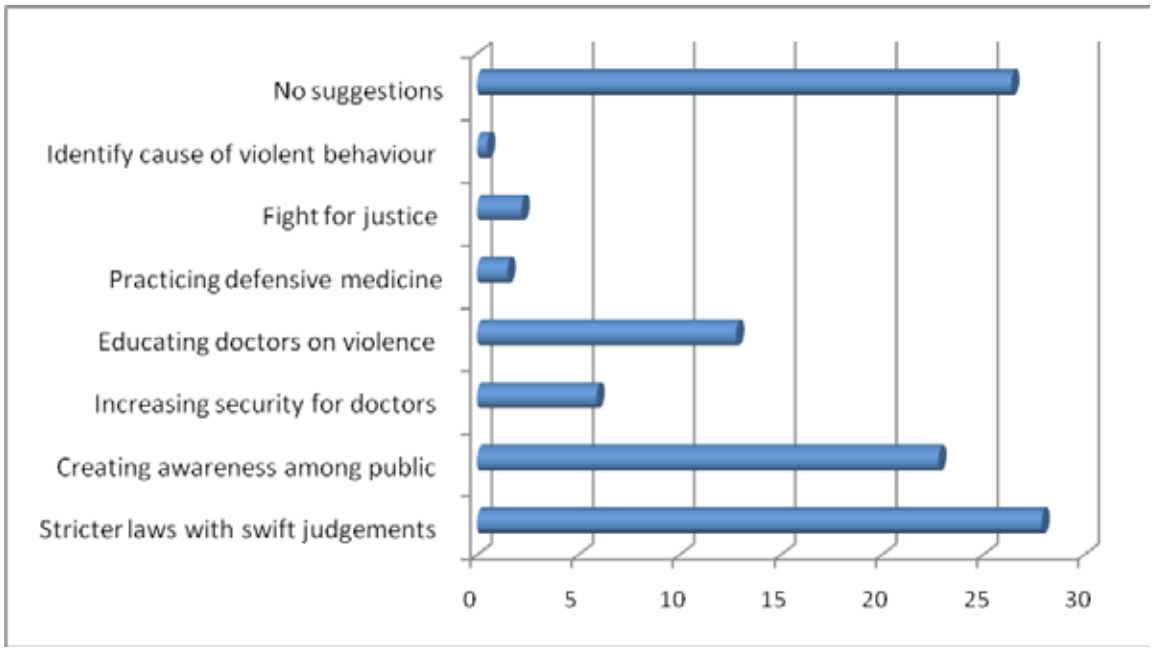

Fig 1: Student suggestions regarding violence on doctors in percentages

Discussion

Based on a study conducted by Rajesh et al in 2017, there has been a recent rise in vandalism cases, majority of them were reported between 2014 and 2016.[4] These violent incidents are not exclusive to government hospitals but occurred in private setups too. 99.8% students were aware of the rise in incidence of violence on doctors. 91.6% students had heard about these incidences through media, 6.7% through friends and colleagues and 0.5% through family. Though media is playing a key role in creating awareness about such incidences, it is known to twist facts for the purpose of sensationalization. Only 1.2% of the participants were made aware through teachers or professors in college about this issue. Teachers in medical colleges should play a major role by conducting live discussions and debates among students so as to identify, prevent and rectify factors leading to this epidemic rise in violence.

Violence on doctors includes physical assault, verbal abuse, warning gestures, telephonic threats and damage to medical equipment/establishment.[5] 77.8% of the students know what constitutes as violence of the

remaining 90 students, 13.3% considered violence as only physical assault and 5.5% opted for combination of physical assault and verbal abuse. 54.8% of students, who chose multiple options, did not consider telephonic threats as part of violence. Also, 14.4% did not consider damage to medical property and 22.2% did not know that warning gestures constitute violence. When asked to mention about a recent incident they have seen, heard of or experienced, 92.1% of the participants mentioned about the physical assault that occurred on a medical resident at Gandhi Hospital, Telangana on 9th June 2020. 5.4% of the participants mentioned various other incidents where doctors were attacked in places like Indore, Kolkata, Vijayawada, etc. All of them had mentioned only about cases where doctors were physical assaulted but none wrote about any incidents involving verbal abuse, damage to clinical establishment or other forms of violence.

Protection of Medicare Service Persons (MPA) and Medicare Service Institutions Acts were passed in 19 states in India. This act was passed in Telangana and Andhra Pradesh in 2008. Even so, 59% of the participants were unaware of them and as per the Act, offenders can be imprisoned for up to three years and pay a fine of upto Rs.50,000 or double the cost of damage to Medical equipment/establishment.[6] But, 53.6% of the students were not aware of the punishments. Offenders can be tried under both the Indian Penal Code (S. 319 and 320 IPC) or MPA Act if they have physically assaulted a doctor. 49.6% of the students knew that a case can be filed under sections for causing hurt or grievous hurt as per IPC but, 46.4% were unaware about this. Nurses and Paramedical staff are directly involved in patient care and equally vulnerable to violence. Medicare Protection Act is applicable for doctors as well as other healthcare providers.[6] But, 30.9% of the participants are not aware of it.

87.9% of the participants did not think that the existing laws are sufficient for protection of doctors from violence. As per study conducted by Gohil RK et al in 2018, only 20% of the cases were reported to the police and majority 56.3% of offenders faced no consequences whereas 23.9% were issued a verbal warning.[7] Hence, there is a need for the laws to not only be strengthened but also enforced. Majority of the participants, 85.2% think that every act of violence on doctors should be thoroughly investigated and punished appropriately, including psychological violence. As per study by Kumar M et al, younger doctors with less work experience were more prone to physical violence.[8] Hence, it would benefit them if workshops and CME programs were conducted on this issue on a regular basis and90.4% of the participants agreed to this.

Study by Kumar M et al concludes that there should be a written policy in the emergency services about the punishments which should be pasted over the walls and other visible areas in hospital vicinity to educate the people.[8] 99% of the students also believe that raising the awareness among public is important which can be done by student unions through social media and other platforms.. Study by Gohil RK et al stated that majority of the doctors are not trained in the measures that need to be taken when facing workplace violence or procedures followed to approach legal help.[7] Thus, 97% of the participants want this topic to be included in the new Competency Based Curriculum in Forensic Medicine subject as a separate chapter.

An open ended question was added at the end of the study which required students to write-in their suggestions and comments about the issue which were broadly classified. 27.9% of the participants mentioned that the government should strengthen the laws relating to violence on doctors and that swift judgements should be passed against the offenders. 22.8% of them said by raising awareness among the people on this issue, the problem can be curbed. 12.8% stated that awareness among medical fraternity about precautionary measures and various protective lawsis important. Other suggestions included increasing security in hospitals and emergency wards, identification and elimination of the underlying causes of violent behaviour, practicing defensive medicine and prioritizing saving themselves over their patients and resorting to strikes demanding justice.

Conclusion

Violence against doctors in India is a multifactorial problem, which may result from unrealistic expectations from doctors, yellow journalism, poor infrastructure in government hospitals or involvement of local leaders/ politicians. In few cases, violent conflicts are inevitable even when proper protocol has been followed by the practitioner or hospital. The existing laws that protect doctors against violence in India are minimal and less stringent, thus resulting in proactive acts of violence due to lenience arising from the current legal scenario. In the current study, it is evident that the level of awareness

among MBBS students about various protective laws against violence is very low, which should be improved. This can be achieved, if the issue "Violence on Doctors" is included in the new competency based curriculum, separately in Forensic Medicine subject. By incorporating this topic into the new curriculum, it will provide a chance to increase the awareness regarding such acts of violence from the undergraduate level itself, equipping them to handle such incidents in a proper manner legally in their future medical practice.

Study of Production and Characterization of Laccase Enzyme from Klebsiellapneumoniae K7 Isolate

Doaa Khalid Mezaal[1], Essam Fadel Al-Jumaili[1], Ahmed Majeed Al-Shammari[2]

[1]Doctorol Degree Student, Prof., Biotechnology Dept. Genetic Engineering and Biotechnology Institute for Post Graduate Studies/University of Baghdad/Iraq, 2Assiant Prof., Experimental Therapy Dept. Iraqi Centre for Cancer Medical Genetic Research, Mastansiriyeh University

Abstract

Sixty four local isolated of *Klebsiella* spp. have been isolated from environment samples (soil and water). These isolates were identified and diagnosis according to phenotype and biochemical tests. These isolates were subjected to primary and secondary screening, to select the isolate with the highest laccase activity. Fifteen isolates chosen from primary screening for screening their enzyme activity in secondary screening. It has been found the *Klebsiella*(K7) has the highest productivity of the enzyme (12 Unit/ml).*Klebsiella*(K7) isolate was diagnosis by Vitak 2 system, it was identified as*K. pneumonia.* The laccase purified was characterization, the experiments showed that: The molecular weight of laccase was 120KD and the optimum pH for the purified laccase activity was 4.5 and forstability was 6.5. the optimum temperature for enzyme activity was 40ºC,the enzyme showed that laccase lost 22, 23 and 20% of its initial activity at 20, 25 and 35°C, respectively.

Keywords: *Klebsiella (K7, laccase enzyme, Enzyme characterization, Enzyme kinetic.*

Introduction

Laccase (EC 1.10.3.2) is one of the important of multicopper oxidasesenzymes, these enzymes have the ability to oxidize a wide range of organic, and inorganic compounds, including diphenols, polyphenols, substituted phenols, diamines and aromatic amines, this reaction would reduction of molecular oxygen to water[1]. Bacteria are become a featured source of laccase production, the used of bacterial laccase in different applications are growing rapidly, this is due to many reasons such as bacteria are easy to handle, the word in different environmental conditions and the bacterial laccase activity and stability at high temperatureand natural pH[2]. *Klebsiella* spp. is one of the interesting laccase source[3]. The *Klebsiella*is a genus of Gram-negative, non-motile,facultative anaerobic, rod-shaped (ranging from 0.3 to 1.0 μm in width to 0.6-6.0 μm in length), generally with polysaccharide-based capsule bacteria. Unlike other enzymes of oxidoreductases and peroxidase[4], The bacterial laccases were found to be thermostable and alkaline stable by Sharma *et al.*[5]. Laccase activity vary by changing pH, this variation may be due tothe reaction caused by the binding of enzyme to substrate,ionization of the substrate, oxygen, or the enzyme itself[6]. The most thermos table laccases have been isolated frombacteria; the half-life of *Bacillus subtilis* CotA was 112 min at 80°C[7] and that of *Streptomyces lavendulae* laccase was 100 min at 70°C[8]. These properties of laccase make it has many applications in industrial, environmental (paper, pulp, textiles and bioremediation) and in medical fields (synthesis complex medical products such as antibiotics and anticancer drugs)[9]. The aim of this study is an attempt to screening of laccase producing *Klebsiella*, and select the isolate with the highest enzyme activity and characterization of laccase enzyme.

Materials and Method

ABTS plate screen assay: The isolates showing methyl orange degradation were further screened for enzyme laccase, on this media which prepared by adding 0.2 mM ABTS and 0.1 mM $CuSO_4$ (after filtering them) in Mineral Salt Agar. Blue green oxidation zone around the bacteria colony indicated the presence of laccase.

Laccase assay: Laccase activity was monitored by measuring the maximum absorption of oxidation of ABTS at 25ºC as a substrate. The reaction mixture containing 1ml of crude enzyme and 1ml of ABTS (0.2mM). The oxidation of ABTS was determined by measuring the absorbance at 420 nm. The blank mixture containing 1ml of sodium acetate buffer (0.1mM, pH5) and 1ml of ABTS . Laccase activity was calculated as follows:

$$\text{Laccase activity } \left(\frac{U}{ml}\right) = \frac{A \times V \times 106}{€\ ABTS \times t \times v}$$

Where: A: Absorbance at 420nm; V: Total volume of reaction mixture in (ml); € : molar extinction coefficient of ABTS =36000$M^{-1}cm^{-1}$; t:incubation time (1min) and v: volume of enzyme used in (ml)[10]. Protein concentration was assayed by the method of Bradford[11].

Effect of pH on Enzyme Activity: The effect of pH on the activity of the laccase was determined at 37°C in 0.05M Tric-HCl buffer (pH 3,3.5,4,4.5,5,5.5, 6) 0.05 M sodium phosphate buffer (pH 6.5,7,7.5,8) and 0.05M Tris-base buffer (pH 8) . The laccase activity was determined at different pH (4-9) by mixing 1ml of ABTS with 1ml of purified enzyme and the activity was measured with different buffers.

Effect of pH on Enzyme Stability: The effect of pH on laccase stability was examined by adding 1ml of enzyme of to a test tubes containing buffer at different pH (3, 3.5, 4,4.5, 5,5.5,6, 6.5,7,7.5,8), and incubated 30min at 37ºC in a water bath, then added the ABTS to mixer and measured the activity with different buffers.

Effect of Temperature on Enzyme Activity: The temperature profile of the purified enzyme was studied by measuring the activity at different temperatures (25,30, 35, 40, 45, 50, 55, 60) ˚C . The purified laccase solution was incubated with ABTS in different temperatures for 10 min and the activity was determined.

Effect of Temperature on Enzyme Stability: The purified laccase was incubated at different temperature ranged between (25,30, 35, 40, 45, 50, 55, 60, 65,70)˚C . followed by incubation in ice bathfor 30min. The enzyme activity was assayed using ABTS, and the relation between remaining activity (%) toward temperature was plotted to determine the optimum temperature of laccase stability.

Laccase Kinetics :K_m, V_{max} values determination: Pre-steady state kinetic analysis was performed using ABTS at different concentration (0.1, 0.15, 0.2, 0.25,0.3mM) in 0.1mM of sodium acetate buffer at pH 5 and estimate the enzyme activity, then the initial velocity (V_o) value was estimated. The relationship between [1/ V_o] versus [1/S_o] was plotted to determine the K_m and V_{max} values according to Lineweaver-Burk reciprocal plot.

Results and Discussion

Screening of *Klebsiella pneumoniae* Isolates for Laccase Production: Out of sixty four *Klebsiella pneumoniae* isolates, there were thirty isolates showed a clear zone around the colony on methyl orange plate, these isolate further screened for enzyme laccase on ABTs plate, it found that twenty one give a positive results . The activity of the enzyme of the fifteen isolates of *K. pneumoniae*, that have ability to produce laccase, was measured to select the highest isolation activity for choose the isolate that have the highest activity (Table 1). The laccase activity was monitored by measuring the maximum absorption of oxidation of ABTS as a substrate.

Table (1) : Screening the *Klebsiella pneumoniae* producing Laccase enzyme.

***Klebsiella pneumoniae* Isolates**	**Enzyme activity (Unit/ml)**

K2	7.60
K3	10.23
K4	10.06
K5	9.37
K6	6.57
K7	12
K8	6.78
K9	7.83
K10	9.54
K11	6.97
K12	7.94
K15	7.21

Molecular Weight Determination: The moleculare weight of purifed laccase was determinaed by Gel filtration chromatograph, which depending on the size of the separated molecules with their charge[12], using Sephacryl S-200. The results in Figure (2) shows the relationship between logarithm of molecular weight and (Ve/Vo) of four different standard proteins in gel filtration column include Catalase (232KD), Arginine Deaminase (125.892KD), Bovine Serum albumin (67KD) and Pepsin (34.5KD), these proteins and laccase were eluted individually. The results in indicated that laccase has a molecular weight of (120KD). The molecular weight of laccase was determined which that purified from *c-Proteobacterium* JBBy using ABTS as substrate[13]. Also, Siroosi*et al.*[14] estimated molecular weight of laccase from *Bacillus* sp. WT to be 180KD and Verma and Shirkot[15] purified laccase from *Geobacillusthermocatenulatus*MS5 with molecular weight 42.5KD.By using another different substrates of laccase the molecular weight was estimated.

Effect of pH on Enzyme Activity: The optimum pH for laccase activity was determined with ABTS as substrate in a pH range of (3-7) . As results in Figure (1), it was found that the best pH of laccase activity in ranged between (4,4.5 and 5), with a maximum and sharp decline in enzyme activityat pH 4.5 with enzyme activity (2.8 U/ml).While, observed that enzyme activy was reduced at nearly acidic pH (3,3.5) and at alkaline pH (5.5-7).

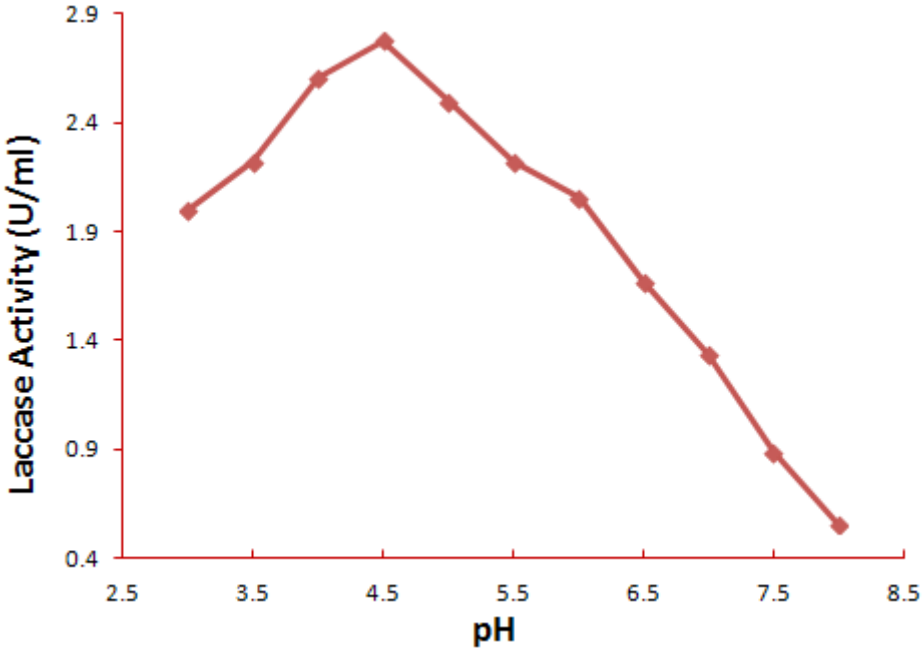

Figure (1): Effect of different pHon Laccase activity.

Verma and Shirkot[15], and Liu *et al.*[16] were purified laccase from *Pseudomonas aeruginosa*, *Ochrobactrum.* sp.531 and *Thermu- thermophilus* SG0.5JP17-16, receptivity by using ABTS as a substrate, found that the optimum pH of laccase activity was at 4.5. The optimum pH on laccase activity was at 4.5, which purified from*Trametes versicolor* .[17]

Compared to phenolic substrates, the redox potential of ABTS does not depend on the pH, oxidation does not involve the protons . So, the effect of pH on the laccase activity towards the different substrates could be related to the balance between the two opposing effects, first the redox potential difference between the substrates and type 1 copper site and second binding of hydroxide anion (OH^-) to the type 2/type 3 copper site[18].

Effect of pH on Enzyme Stability: Figure (2) shown that the optimum pH of laccase stability ranged between 6-7 and the a maximum stability was at pH 6.5, where the enzyme retained 100% of its activity. While, retained 94.42% of its activity at pH 6 and about 94.42% and 82.03% at pH 7.

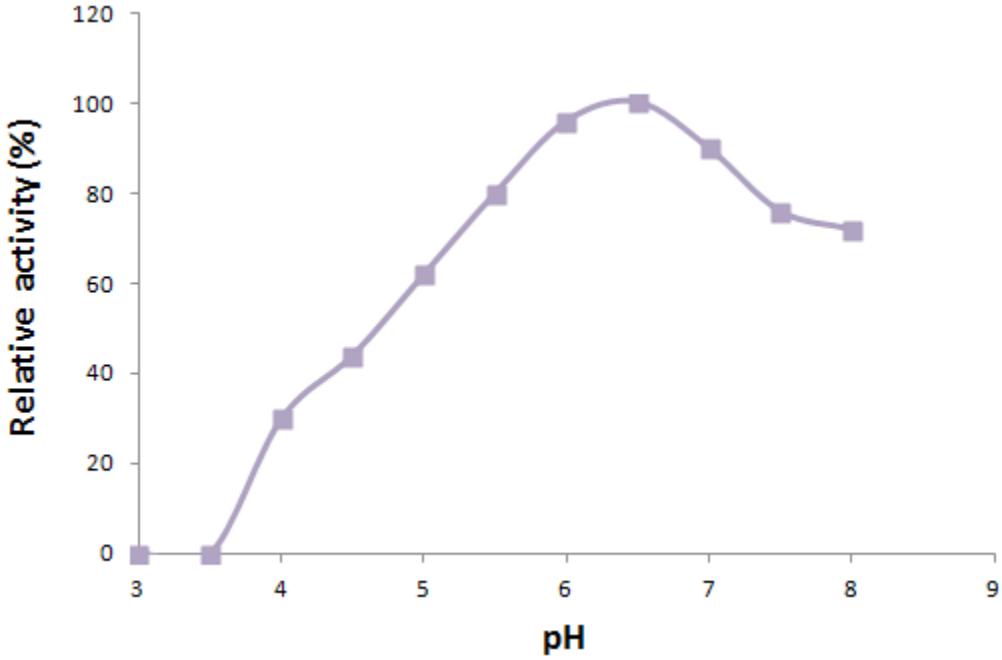

Figure (2): Effect of different pHon Laccase stability

The reason for decreasing in enzyme stability at acidic pH is due to the effect of acidic environment in enzymatic structure which cause ionizing groups in active site. The declining in enzyme activity at pH above the optimum pH may be due to irreversible denaturation of enzyme molecule that leads to change in enzyme structure associated with the formation of enzyme dimerization that leads to enzyme autolysis[19].

Effect of Temperature on Enzyme Activity: The temperature profile of the laccase was studied by measuring the activity in a range of 25–60ºC with 5°C interval. The results in Figure (3) showed an increase in laccase activity towards 40°C with an activity of 3.17 U/ml. After 40°C the activity decrease and the minimum activity was recorded at 60°C which was 2.5 U/ml.

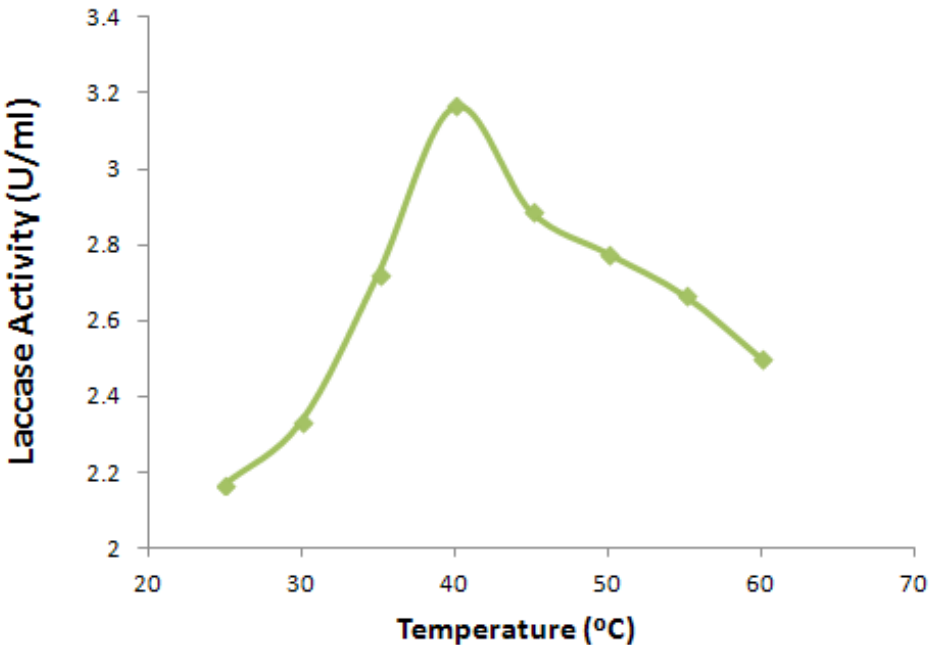

Figure (3): Effect of different temperatures on Laccase activity.

Siroosi*et al.*[20] determined the optimal temperature of laccase activity at 37 °C, which purified from *Bacillus sp. WT*, *Pseudomonas aeruginosa* and *Rhodococcus sp.*, respectively. Demissie and Kumar[21] found the optimal temperature, that purified from *Streptomycetes sp.* was at 35 °C. While, temperature was 35 °C of laccase from *Pseudomonas luridastrain LR5.1* determined by Dhiman and Shirkot[22]. The reason for decreasing of an enzyme activity towards higher temperature is that the speed of enzyme interaction increase with increasing temperature within a certain range due to increased energy kinetics and the collisions between enzyme molecules and substrate, except that the high temperatures within certain limits lead to denaturation of the enzyme and loss of three dimensional structure and then decline in enzyme activity.[23]

Effect of Temperature on Enzyme Stability: The thermostability of laccase was determined at temperatures ranging from 25 to 60°C . The results in Figure (4) showed that laccase lost 22, 23 and 20% of its initial activity at 20, 25 and 35°C, respectively.

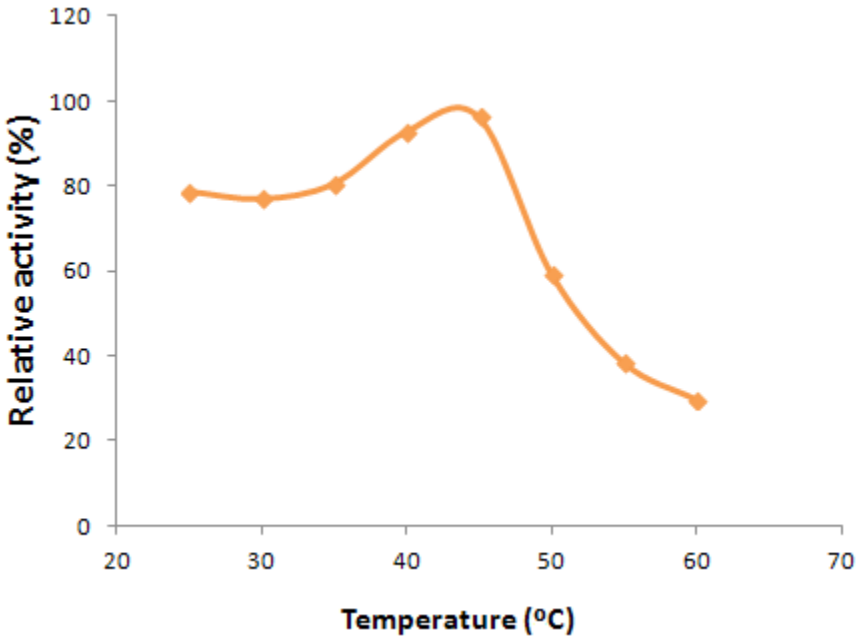

Figure (4): Effect of different temperatureson Laccase stability.

Most cold-adapted enzymes exhibit poor thermal stability at temperatures above 40°C, and their activity decreases as temperature increases.[24]

The reduction of activity above 40°C is due to sensitivity to high temperature, reflecting the effect of temperature on the three dimensional structure of protein by damaging R-groups of amino acids which lead to denaturation of protein and losing its activity. In general, laccases are stable at 30-50ºC and rapidly lose activity at temperatures above 60ºC[25].

Determination Km, Vmax Values: As shown in Figure (5) relation between substrate concentration ABTS and enzyme activity. Activity was measured at different ABTS concentrations (0.1, 0.15, 0.2, 0.25 and 0.3mM) in 0.1mM of sodium acetate buffer at pH 5.

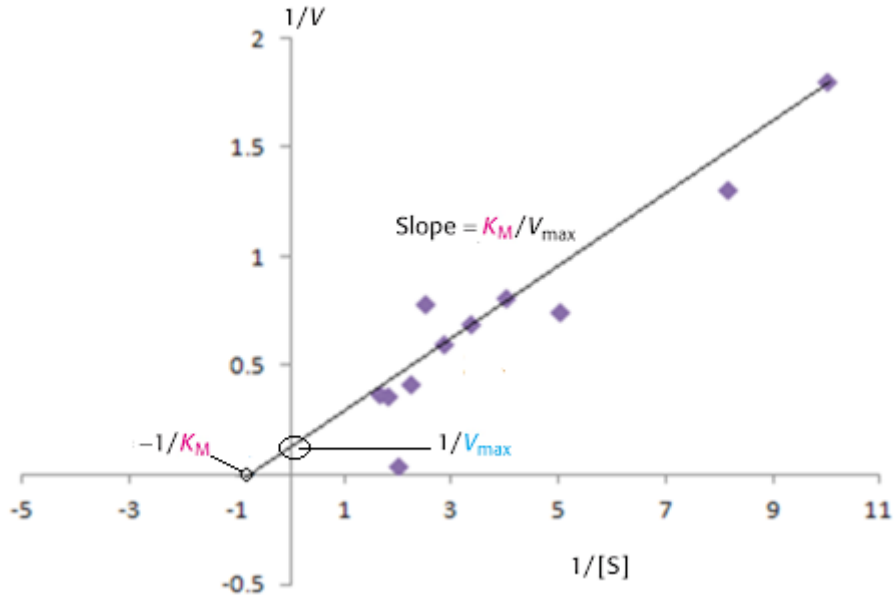

Figure (5): Lineweaver-Burk double reciprocal plot of (1/Vo) versus the [So] for the purified laccase.

Singhal *et al.*[34] characterized laccase enzyme activity produced by *Cryptococcus albidus*, ABTS was used as a substrate. By Michaelis–Menten kinetics the K_m was 0.8158 mM and V_{max} was 1527.74 U/mg. The Km of laccase purified *Bacillus subtilis*CotA by Martins *et al*[7] was 0.106mM. Laccase purified from *K. pneumoniae* by using ABTS as substrate. The K_m values were 0.467, 3.97 and 0.38mM for NITW715076, NITW715076_1 and NITW715076_2 *K. pneumoniae* strains, respectively[26].

Conclusion

K. pneumonia have been proved to its ability to produce laccase. And The molecular weight of laccase was determined at 120KD. The optimum pH of enzyme activity and stability is 4.5 and 6.5, receptivity. The optimum temperature for laccase activity is 40ºC while forstability is (20- 35ºC).

Transformation of the Social Insurance Management Agency on Health

Endang Sulistyaningsih[1], Hartiwiningsih[2], Is Haryanto[2]

[1]Doctoral Student at Legal Studies, Sebelas Maret University, Surakarta, Indonesia,
[2]Lecturer at Sebelas Maret University, Surakarta, Indonesia

Abstract

Health insurance is a type of insurance product that specifically guarantees the cost of health or care of the insurance members if they are sick or have an accident. Implementation of social security is a state obligation mandated by the 1945 Constitution. The issuance of the Social Insurance Management Agency (BPJS) act as the implementer of the National Social Security System act (SJSN) resulted in PT Askes transforming into Social Insurance Management Agency on Health (BPJS Kesehatan). The National Social Security System is organized on the basis of humanitarian principles, principles of benefit, and the principle of social justice for all Indonesians. The National Social Security System aims to provide and guarantees the fulfillment of a decent life base for each participant and/or his family member. The National Social Security System is organized on the basis of such principles: mutual cooperation, non-profit, disclosure, prudence, accountability, portability, mandatory membership, trust fund, and the social security fund will be used entirely for program development and for the interest of participants. Although the preparation and implementation of the National Social Security System is quite well, but in reality there are still various impacts and problems encountered in the operation of BPJS Kesehatan such as lack of socialization, service facilities, inappropriate data, and personnel who are still lacking in giving a good services and information.

Keywords: *Health insurance, legal analysis, transformation, BPJS Kesehatan.*

Introduction

Health insurance is a type of insurance product that specifically guarantees the cost of health or care of the insurance members if they are sick or have an accident. Health insurance is a type of insurance product that specifically guarantees the cost of health or care of insurance members if they fall ill or have an accident. Health insurance products are usually provided by social insurance companies, life insurance companies, and general insurance companies. In Indonesia, PT Askes Indonesia is one of the social insurance companies that organize health insurance for its members in need both for civil servants and non-civil servants. Their children will also be financed until the age of 21st. It also applies to pensioners.

PT Askes (Persero) is a State-Owned Enterprise specially assigned by the government to provide health care insurance for Government Civil Servants, TNI (Indonesian National Army), POLRI (Indonesian National Police), pensioners, veterans, families of the pioneers of Indonesian independence and other Business Entities. Health Insurance Program (ASKES) which is organized under Government Regulation No. 69 of 1991 is mandatory for civil servants/recipients of pensions/ pioneers of independence/veterans and members of their families.

Over the last few decades, Indonesia has implemented several social security programs. The law that specifically regulates social security for private

Corresponding Author:

Sebelas Maret University, Jl. Ir. Sutami No. 36, Jebres, Surakarta, Central Java 57126, Indonesia

workers is Law No. 3 of 1992 on Social Security of Workers (JAMSOSTEK) which includes health care insurance program, accident insurance, old-age insurance and death insurance. For Civil Servants (PNS), there are savings fund program and Insurance of Civil Servants (TASPEN) which were established under Government Regulation No. 26 of 1981. Besides that, there is also Health Insurance Program (ASKES) which is based on Government Regulation No. 69 of 1991.

For Indonesian National Army (TNI), members of the Indonesian National Police (POLRI), civil servants of the Department of Defense/TNI/POLRI and their families, the Indonesian Armed Forces Social Insurance (ASABRI) program has been implemented in accordance with Government Regulation No. 67 of 1991 which is a change from Government Regulation No. 44 Year 1971.

Programs mentioned above cover only a small percentage of Indonesian, while the majority of them have not received adequate protection. In addition, the implementation of various social security programs has not been able to provide fair and sufficient protection to the participants in accordance with the benefits of the program which are the rights of participants. In relation to the above, it is deemed necessary to develop a social security system capable of synchronizing the various forms of social security implemented by some organizers in order to reach wider membership and provide greater benefits for each participant.

Act 4 of the BPJS Law (No. 24 of 2011) contains BPJS principles such as mutual cooperation, non-profit, disclosure, prudence, accountability, portability, mandatory membership, trust fund, and the social security fund will be used entirely for program development and for the interest of participants.

The non-profit principle in BPJS is different from the goal of the establishment of state-owned enterprises, which is to pursue profits to improve the company. The principles set forth in the BPJS law will change many things in the implementation of social security in Indonesia. The preparation period of the transformation from PT ASKES (Persero) to BPJS Kesehatan was starting from November 25, 2011 to January 1, 2013. It has started on January 1, 2014 and also explained the purpose of the transformation is to make it easier and improve health insurance services to the public. One of the principles of BPJS Health is the principle of mutual cooperation which means to help each other so that the social security system is in accordance with the basic philosophy of 5th principle of Pancasila (Social Justice for all Indonesian people). The focus of this paper will discuss the implementation of Article 57 of the BPJS Law concerning the transformation of PT ASKES (Persero) into the BPJS Kesehatan and the juridical implications of its' transformation.

Utilitarianism, Theory of Law and Social Change: The theory of utilitarianism was conceived to state that the law is made to benefit the society and the law should be based on benefits for human happiness.[1,2] So, this understanding assesses whether it is good or not in terms of usefulness or benefits that it comes. The basic principle of utilitarianism is a moral act or regulation that can support the happiness of all concerned so that it can benefit all citizens.

The development of material law and procedural law follow certain stages, ranging from simple form to the most advanced stage in which law is organized systematically.[3] He states that the changes of the law are in accordance with the changes that occur in the social system of society that supports the legal system.

The law is said to be a tool for changing society, as it is known that the law was born by man and to guarantee the interests and rights of man himself. From this man the color of law and its application will determine what he will experience in the association of his life.[4] Law is a tool to change society. It means that the law is used as a tool by the agent of change or a pioneer of change (a person or group of people who gain the trust of the community as the leader of the community institutions).A planned social change is always under control of the pioneer of the change. Therefore, if the government wants to establish bodies that have function to change society, then the law is required to establish the body to determine and limit its power.[5]

Health Insurance Management on National Constitution: Pancasila and the 1945 Constitution mandated that the state has a responsibility to protect the entire Indonesian and promote the general welfare in the context of realizing social justice for all Indonesian people. It is to realize a decent and dignified life and to fulfill the right to the basic needs of the citizens for the achievement of social welfare, the State organizes the service and development of social welfare in a planned, directed and sustainable manner. State and social security are components that integrate with social protection

systems. National social security systems include health insurance, life insurance, accident insurance and pension benefits financed by employer contributions and employee contributions. The National Social Security System (SJSN) is a lifelong social program that forms a social protection system composed of parts of the approach system in the provision of social security and as an effort to create jobs by the government and empowerment of the marginal community to become a prosperous self-reliant community.[6] The National Social Security System which is based on Law No. 40 of 2004 (about the National Social Security System/SJSN) is a state program for a lifetime that must be held by a public legal entity with permanent legal force.To answer the problem of juridical study of the transformation of PT Askes (Persero) into BPJS Kesehatan, the writer uses Utilitarianisme Theory and Social Change Theory.

Implementation of Article 57 BPJS Law on Transformation of PT Askes (Persero) into BPJS Kesehatan: The definition of policy implementation according to Van Metten and Van Horn is acts committed by individuals, officials, government, or private groups directed to achieve the objectives outlined in policy decisions.[7]

As it is known that PT Askes (Persero) is a State-Owned Enterprise (BUMN) that organizes a social security program, its capital is partly or wholly owned by the government. There are 3 kinds of BUMN. First, Perjan is a BUMN whose capital is owned by the government. Perjan is service-oriented towards the community. Second, Perum is a Business Entity managed by State whose purpose is to gain profit and provide services to the public. Third, Persero is one of the Business Entities managed by State or Region. Unlike Perum or Perjan, the main purpose of establishing a Persero is to seek profit (commercial).

At the beginning, the form of business entity of PT Askes (Persero) was in the form of a public company (Perum) under the name of Perum Husada Bhakti and based on Government Regulation No. 6 of 1992, the status of Perum was changed to a company (PT) and then on January 1, 2014 PT Askes (Persero) changed its name to BPJS Kesehatan based on Law Number 24 of 2011 on BPJS.

Characteristics of BPJS Kesehatan that different from other BUMNs is to pursue profit in order to increase the value of the company. BPJS Kesehatan is oriented to serve community. It has a non-profit principle, the management of trust funds by BPJS Kesehatan is not for profit (for profit oriented) but to meet the maximum interests of participants. Funds collected from participating are trust funds which is managed for the welfare of the participants. So the results of its development will be utilized as much as possible for the benefit of participants.

As a private legal entity, a Persero Company is not established by a state authority with a law but established by an individual, as any other public company should be registered with a Notary and authorized by the Ministry of Justice and Human Rights.

In contrast, the establishment of the Social Insurance Management Agency (BPJS) by state authorities is established under National Social Security System Act and Social Insurance Management Agency Act. The establishment of BPJS is not registered with a notary public and does not require the authorization of a government agency.

The main obstacle encountered by BUMN Persero is the ineffectiveness of social security law enforcement because there is no authority to regulate, supervise or impose sanctions on participants. On the contrary, the BPJS as a public legal entity has the power and authority to govern the public through the authority to make public binding regulations. As a public legal entity, BPJS is obligated to convey responsibility for the performance of its duties to the President. BPJS deliver its performance in the form of annual program management and financial report audited by a public accountant to the President with carbon copy to the National Social Security Board, no later than June 30th of the following year.

In 2004 the government established and enacted Law Number 40 of 2004 on National Security System as the implementation of Article 5 paragraph (1) and Article 52 of the National Social Security System Law after the Constitutional Court's decision No. 007/PUU-III/2005 dated 25 November 2011 and enacted Law Number 24/2011 on the Social Insurance Management Agency. BPJS Kesehatan starts to operate on January 1st, 2014 and PT Askes (Persero) was closed without liquidation. At the same time, the Minister of BUMN through the General Meeting of Shareholders approved the report on closing financial position of PT Askes (Persero) after the audit at the public accounting firm and the Minister of Finance authorized the opening financial position of

BPJS Kesehatan and the opening social security fund report. For the first time, the Board of Commissioners and the Board of Directors of PT Askes (Persero) was appointed as BPJS Kesehatan Supervisory Board for a maximum period of 2 years since BPJS Kesehatan started to operate.

The final change from the transformation processes of BPJS is the change of organizational culture.[6] In Article 40 paragraph (2) of BPJS Law, it requires BPJS to separate the assets of BPJS and the assets of the Social Security Fund. Article 40 paragraph (3) of the BPJS Law affirms that the assets of the Social Security Fund are not an asset of BPJS. This assertion ensures that the Social Security Fund is a trust fund of all participants and not the assets of BPJS.

Furthermore, in Article 4 of BPJS Law, it regulates BPJS principles: principles of mutual cooperation, non-profit principles, principles of openness, prudential principles, accountability principles, portability principles, compulsory membership principles and trust fund principles.

Juridical Implications of the Transformation of PT Askes (Persero) into BPJS Kesehatan: The legal basis for the transformation of PT Askes (Persero) into BPJS includes Law Number 40 of 2004 regarding National Social Security System and Law Number 24 of 2011 on BPJS.Furthermore, some Government Regulations (PP) and Presidential Regulations (Perpres) also regulate the implementation of BPJS Kesehatan. From the various legal basis underlying the transformation of PT Askes (Persero) into BPJS whether it is based on the Law, Government Regulation, or Presidential Regulation, there are various impacts or consequences of it. For the company, the impact is that the company must register its employees to BPJS Kesehatan. Furthermore, company are required to allocate funds to pay contributions to BPJS Kesehatan. For society, the impact is that membership is mandatory and participants must pay the contribution.

Factors that impede the implementation of the National Health Insurance currently encountered by BPJS Kesehatan are some, including (1) lack of socialization; (2) inadequate number of health service facilities and uneven distribution, especially for remote areas, borders and islands with low service levels due to geographical conditions and poor health facilities in the area; (3) lack of treatment room facilities resulting in many patients experiencing delay in handling because they have to wait for an empty treatment room to be served (especially at government hospitals); (4) the number of health personnel is less than the required amount; (5) the problem will arise in the contribution participants (PBI) because the data is not in accordance with conditions in the field so this causes serious problems.

Conclusion

Based on Government Regulation No. 6 of 1992 the status of Perum is changed to a Persero company and from January 1, 2014, PT Askes changed its name to BPJS Kesehatan based on Law no. 24 of 2011. At that time PT Askes (Persero) was closed without liquidation and also accompanied by the transfer of assets, rights and obligations of PT Askes (Persero) and its employees moved into BPJS Kesehatan. Characteristics of BPJS are oriented to serve community. Funds collected from participants' contribution are trust funds that will be managed for the welfare of participants. The juridical implications of PT Askes (Persero) transformation into BPJS Kesehatan is affecting the company where it is required to register its employees to BPJS Kesehatan and the company must allocate funds to pay the contribution of BPJS Kesehatan. Impact for participants or communities is participants must pay contributions to BPJS Kesehatan except for whose premium paid by the government.

Abstract

In this paper, combinations of a ceramic mixture with a polymer were developed to be used as a substitute for damaged bones or teeth. Overlays were prepared using the manual mixing method, followed by the use of ultrasound technology to ensure uniform distribution of the powder within the polymer. The polymer (PMMA) is supported with a ceramic powder (HAMgO) prepared using an effective mechanical mixing method. Where the percentages were used for consolidation, starting from (1%-4%). The results of the tests showed mechanical corrosion or the so-called wear and tear of a significant improvement for the reinforced polymeric compounds as the corrosion rate decreased to less than half at 4%. Likewise, the results of the particle hardness examination showed a successive increase in the percentages compared to the polymer base material. The results of the durability of compressibility and the Yunk coefficient showed a direct increase with the increase in the percentages of the added ceramic powder. The results were interpreted using the scanning electron microscope and by relying on the density values approved from the results of the exercise.

Introduction

Polymeric composites have unique properties that qualify them to work in all fields, including industrial, medical and engineering, in addition to their use in military applications and in the manufacture of spacecraft[1,2]. Many researchers in this field were interested recently in this century in developing and producing polymeric-based compositions that act as materials that have the ability to withstand various mechanical stresses and have the ability to operate in harsh environmental conditions[3,4]. In light of this, many researchers were able to prepare polymeric nanoparticles that are used in bone and skeletal alternatives as well as used in the manufacture of teeth and their permanent fillings[5,6]. These prepared compounds underwent high physical and mechanical conditions and showed great success in tolerating scratching and wear and resistance to fracture compression[7,8]. The polymers are histologically compatible with the organism are the most important characteristics in the formation of nanocomposites in this field and the most important medical polymers are (PLA, PMMA, HDPE, PVA, as well as biochemical materials are one of the pillars of the preparation of polymeric compounds for medical compensation use, such as Al_2O, ZrO_2, TiO_2, CaO, HA, MgO[9,10,11]. These compounds have specific properties that have the ability to withstand mechanical stresses and have the ability to resist bacteria and fungi. Most ceramic materials are materials compatible with body tissue and bonding, especially if they are in the nanoscale [12, 13]. Many researchers studied at AH in the field where the researcher *Fadhil K. Farhan and et al*. Prepared polymer compounds supported with binary ceramic powder from and obtained advanced results in improving mechanical properties[14]. The aim of the research is to manufacture Nano molecules based on a polymer supported by a resistant bi-ceramic market Wearing and working in exceptional conditions and in various forms.

Materials and preparation of nanocomposites: The materials were prepared first after they were diagnosed and their ability to work in this field was determined as the polymer was purchased and it is in two parts the first is a liquid called the monomer chloroform and the second part which is the powder imported from the United Arab Emirates and with regard to ceramic powders it has been imported from the US states with a size of 20 nanometers and a purity of 99.998. The overlays were prepared using liquid mixing and ultrasound technology for 10 minutes to ensure a homogeneous distribution between the polymer and the binary powder. Then the models were formed according to the measurements approved in the examination.

Practical part: The PIN-ON- DISC system was used to calculate the sliding wear and tear wear rate of the compounds. Models were created with dimensions of 1 cm in diameter and 3 cm in length. Using the following equations, the final wear rate[15]. Was calculated:

$W_r = \Delta m/S_D$ ……Wear rate (g/cm)

$\Delta m = m_1 - m_2$ ……. Wear loss (g)

$S_D = \pi.N.D.T$ ……. Sliding distance (m)

$V_S = \pi.N.D/60$ ……Sliding velocity (m/s)

Where:

N: 2950 (rive/min)

D: Routing distance (m) = 0.06 m

T: Sliding time (min)

$W_v = W_{r/}\rho$…… Volume Wear

$W_{coeff.} = W_v . H_V/L . S_D$ …….. Coefficient Wear

Where:

ρ:Experimental density (g/cc)

H_V: Number Hardiness (MPa)

With regard to density, the Archimedes method was used to calculate the density of nanocomposites as well as the dimensional method to ensure the accuracy of the calculation. Vickers hardness device was also used to calculate the surface micro hardness of the superposition's where the results were recorded directly from the system in mica units and using a time of 20 seconds and a force of 0.5 Newton where the equation was used:

$Hv = 1875\ p\backslash d^2$ (MPa)

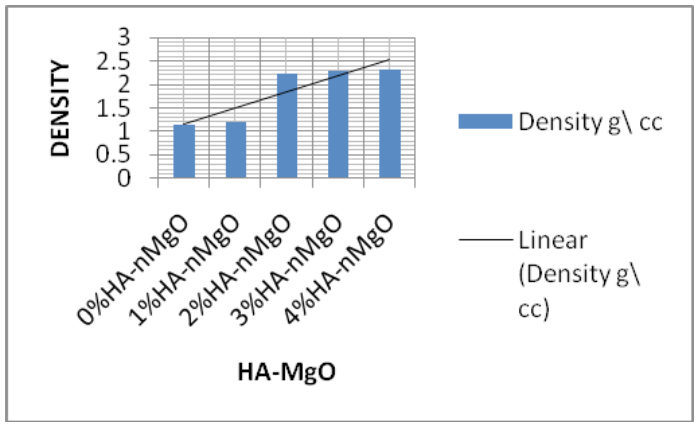
With regard to the compression test, the results were obtained by the examination system, called the universal machine, where the models were formatted as cylinders with dimensions of 2cm x2cm

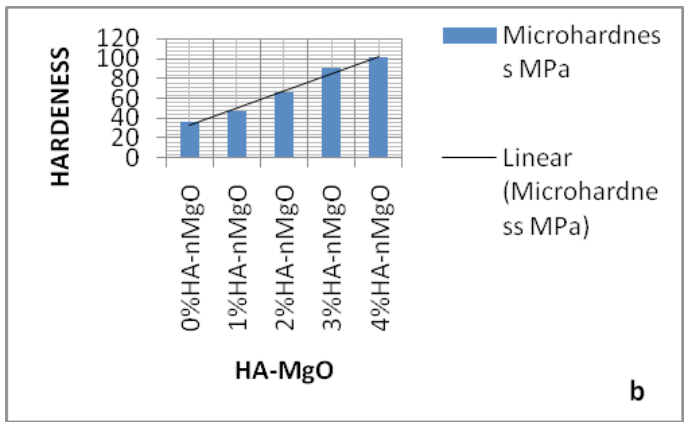
Results and Discussion

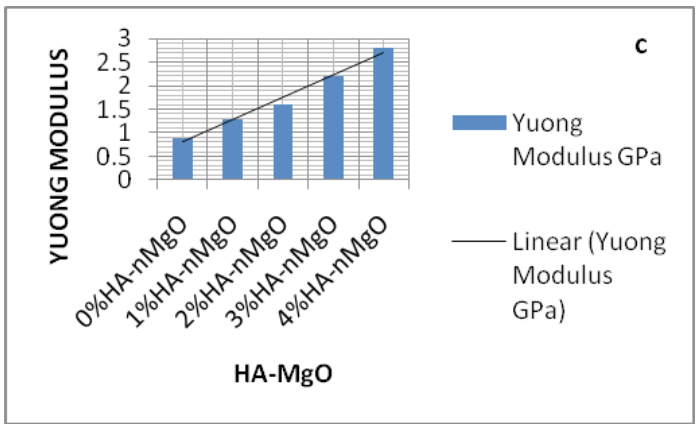
Physical Properties Results: Table No. (1) And Figure (1) show a summary of the practical results of the physical properties that were performed for the prepared models, where the values of the practical intensity that were calculated by the Archimedes method and also were confirmed using the dimensional method. The results showed a significant improvement in the values of practical density with a direct increase with the percentage of additives. The reason is due to the closing of pores and the stacking of particles between the components of the mixed materials. The other reason is due to the high density of the additive and to the high surface area and the nano-scale of it. This is illustrated in Figure 1 of the density.

All other properties, such as particle hardness, compressive strength, young modulus (elastic modulus), all depend mainly on the density values for their structural association with these properties. The hardness values showed a significant improvement and a significant increase in the values of nanocomposites compared to the base material (polymer). The reason is due to the cohesion between the molecules, the substances formed for the compounds, as well as the reason due to the high density possessed by the nanocomposite, and this is shown by Figure (1) of the hardness.

An important test for studying the physical properties is calculating the durability of compression, which is very similar in the mechanism for measuring hardness. The results of compression durability show a clear improvement in the durability values of the compounds compared to the base material. The reason is due to the nanomaterial in transferring stress and distributing it in a way that reduces the failure in the model and this is clearly evident in the figure (compression strength). In Figure 1 of the modulus of elasticity, the great improvement in the values of the modulus of elasticity is evident. This indicates the resistance of the material to compression to a certain extent without any breakdown or collapse. All these properties are consistent with the source[16].







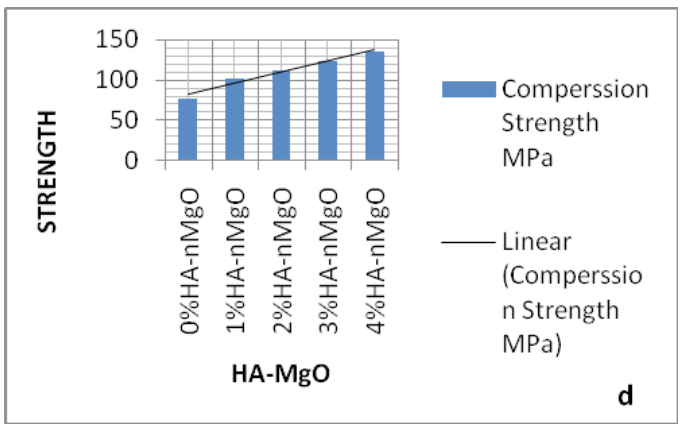


Fig.(1): Experimental of Mechanical Properties (a) Density, (b) Hardiness, (c) young modulus, and (d) compassion with Wight percentage HA-MgO.

Table (1): Practical results of the physical properties of Nano-composites PMMA\HA-nMgO

Samples	Density g\cm^3	Micro-Hardness MPa	Compression Strength MPa	Modulus – Elastic GPa
PMMA\0% HAMgO	1.144	36.2	77.4	0.877
PMMA\1%HAMgO	1.198	46.9	102.4	1.3
PMMA\2%HAMgO	2.22	65.5	111.5	1.6
PMMA\3%HAMgO	2.28	89.7	122.6	2.2
PMMA\4%HAMgO	2.32	100.5	135.3	2.8

Discuss the wear Rate properties: Table 2 and Figure (2.3) show a summary of the practical results of the triple properties of the prepared samples. A screw-on-disk device was used to calculate the dry mechanical corrosion rate of the nanocomposites and the dominant model. The results showed the calculation of the dry sliding wear factor and a clear decrease in the amount of skimming of the nanocomposites. This is due to the improvement of the outer surface of the samples supported by the Nano powder, which led to blocking the pores and voids and strengthening the bonds between the components of the supported sample compared to the unsupported substance (polymer). Therefore, such a work can be used in the dental industry and damaged bone compensation, because these prepared nanocomposites have a high resistance to wear and wear, and this is consistent with the source.

In order to check the practical results of calculating the dry mechanical corrosion rate, the volumetric wear rate was calculated to ensure the accuracy of the calculation. It was included in the calculation of the mechanical corrosion rate, the practical intensity of the prepared models. Figure 3 shows volumetric wear behavior and we note the significant decrease in the volumetric corrosion values of nanocomposites compared to the base material (Polymer).

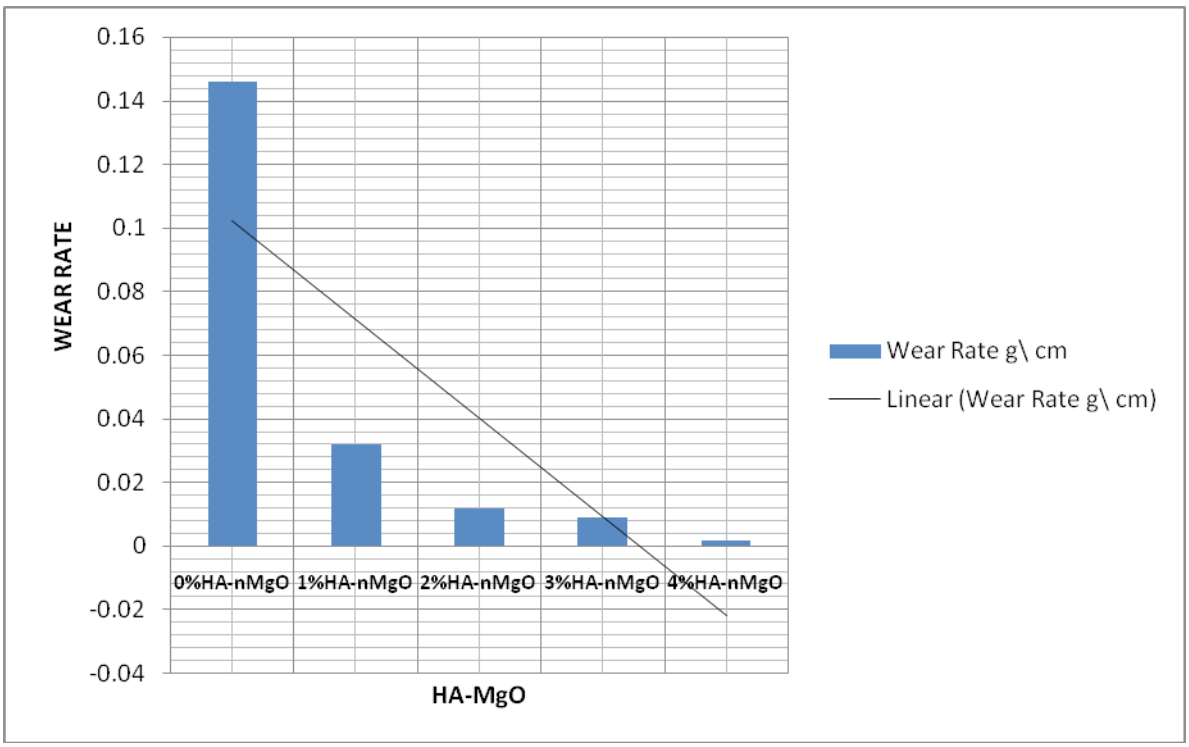

Fig.(2): Experimental Wear Rate with Wight percentage HA-MgO

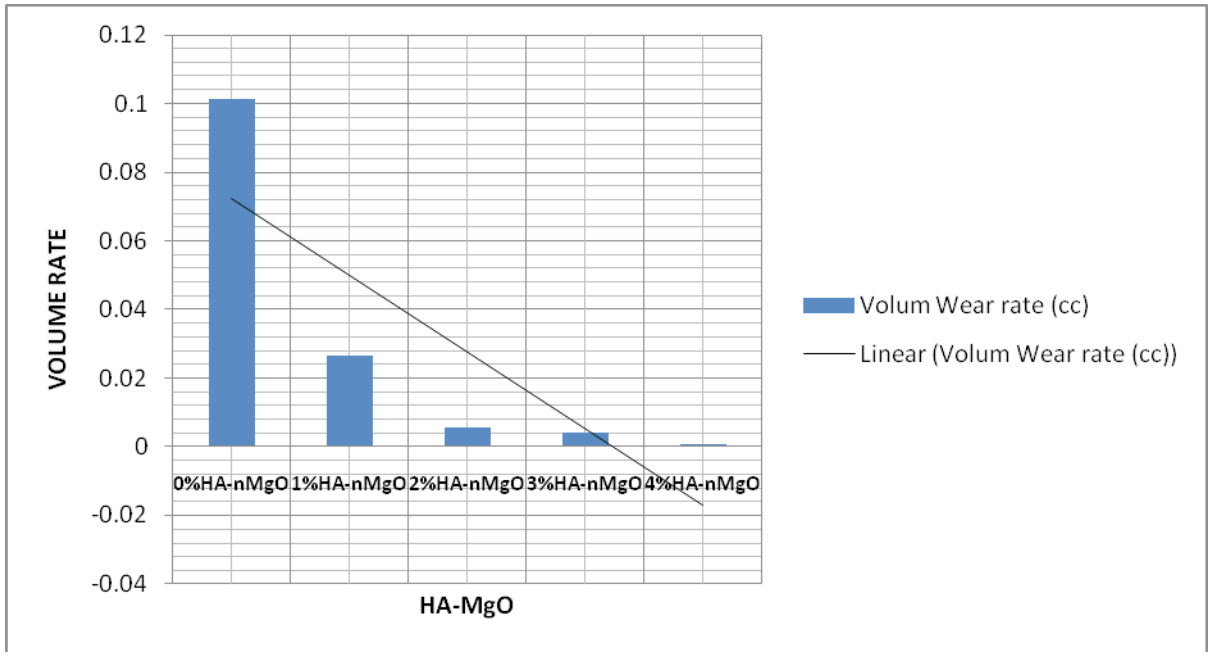

Fig.(3): Experimental Volume Wear Rate with Wight percentage HA-MgO

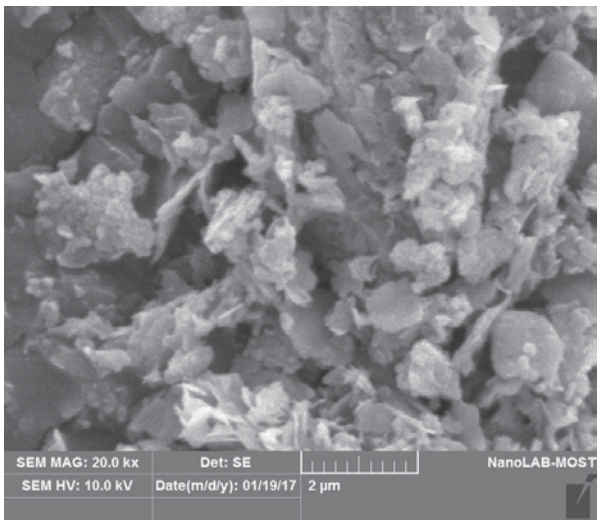
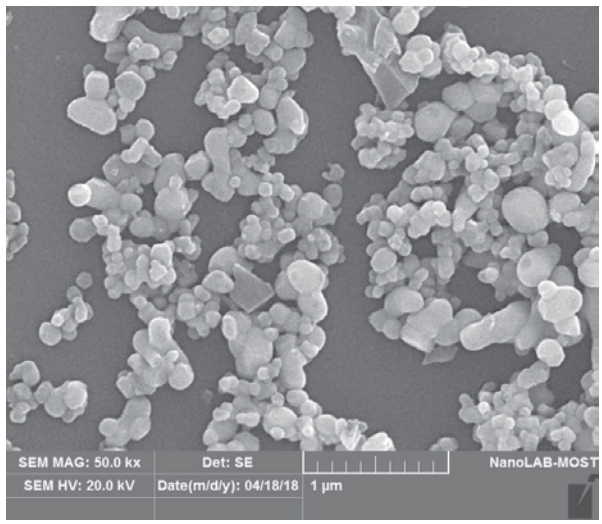
Table (2): Wear rate at 10 min

Sample	Mass before wear (g)	Mass After wear (g)	Wear Rate (g\cm)^10^{-5}	Volume Wear^10^{-6} cm^3
0%HA-nMgO	3.246	3.100	0.146	0.10138
1%HA-nMgO	3.677	3.645	0.032	0.02671
2%HA-nMgO	3.886	3.874	0.012	0.00545
3%HA-nMgO	3.998	3.989	0.009	0.00394
4%HA-nMgO	4.125	4.123	0.002	0.00086

Discuss the results of the scanning electron microscope: Figure (4) shows pictures of the powders forming the HA-MgO compound. Figure (4) a shows the hexa-structure of the hydroxybite with a nanoscale of 20 nm. Figure (4) b shows the fibrous and spindle composition of the nano-magnesium oxide compound, while Figure 4 (c) shows the mixed composition of the two compounds to form a non-distinct homogeneous compound.





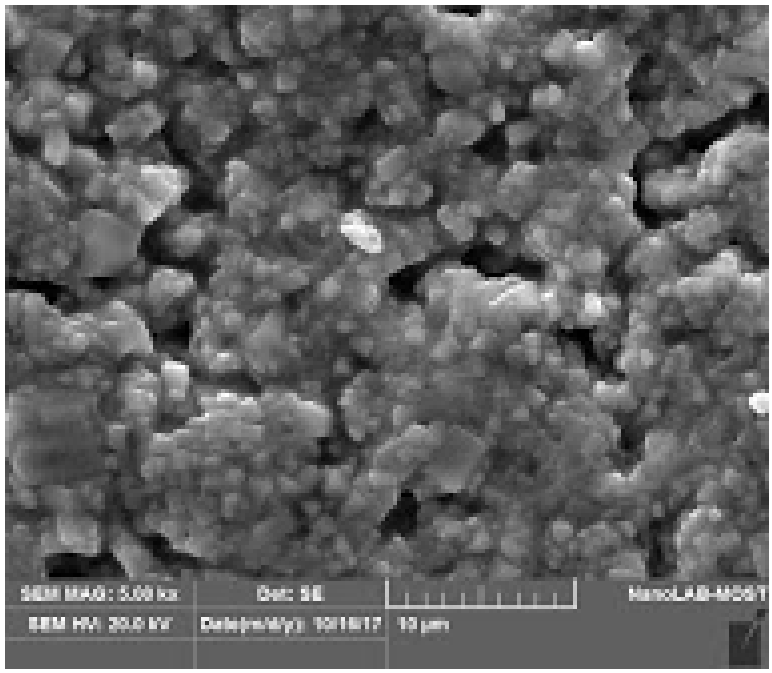


Fig. (4): SEM-Images of (a) HA, (b) MgO, and (c) HA-MgO

Conclusions

We conclude from the above from the current research:

1. The significant improvement in all the physical properties of the nanocomposites is due to the great correlation between the nanocomposite within the polymer molecules, which gives it strength, durability, hardness and an increase in stacking.
2. The significant decrease in the scaling amount of nanocomposites to rates that do not nearly affect the weight and size of the samples is due to the high surface area of the nanocomposite and to the nanoscale used.
3. Scanning electron microscopy images show the shape and size of the compounds involved in the final compound composition, and through them the result was explained in (1,2) in addition to the density values.

Ethical Clearance: This study was approved by the Ethics Committee, University of Karkh for Science. The study protocol was thoroughly explained for using samples of patients and written informed consents were obtained from them prior to participation in the study.

Knowledge and Attitudes of Vaccination among Iraqi Pharmacy Students

Fadia Thamir Ahmed

Master of Clinical Pharmacy (M.Sc.), Lecturer/Deputy Head of Clinical Pharmacy Department, College of Pharmacy/University of Baghdad

Abstract

Objective: Since the vaccination rate is largely affected by low knowledge and negative attitudes of healthcare professionals, so this study aimed to weigh up the vaccination knowledge and attitudes of pharmacy students.

Method: A pilot study using a survey to investigate demographic data, knowledge (20 questions), and attitudes (5 questions) of 156 fifth year and 121 third year pharmacy students from College of Pharmacy/ University of Baghdad.

Results: The mean score of knowledge and attitudes was intermediate (16.654 and 14.917 out of 25 for the fifth and the third grades, respectively) with a significant difference between the two groups, the students shown to have favorable attitudes about vaccination. The score of the students is not influenced by family-related parameters like father's education, mother's education, the number of siblings and preschool children in the family.

Conclusion: A positive attitude and intermediate knowledge level about vaccination among pharmacy students were found. This could be improved by the addition of a specialized vaccinology course to the curriculum in pharmacy colleges and schools in Iraqi universities and going toward implementing the pharmacy-based immunization program for pharmacists by the health authorities which in turn can develop pharmacists' role in the healthcare system in Iraq.

Introduction

Immunization involves the administration of vaccines to individuals in order to develop immunity against any specific disease. The World Health Organization (WHO) states that vaccines are biological substances that are either single substance specified for one disease, combined vaccines in one preparation that immunize the person against more than one disease or they can be live attenuated or weakened viruses that cause mild infection creating immunity against that virus. Immunization may involve the occurrence of a medical incident called the adverse event following immunization (AEFI) that may concern the vaccinated individuals. Controlling AEFIs and monitoring the safety of vaccines will increase immunization programs' credibility[1]. There are wrong concepts about vaccination owned by parents that affect their decisions to vaccinate their children; also some of them have hesitation to take vaccines due to safety issues[2]. This misconception may come from the possible relation between vaccines and different diseases such as Crohn's disease, multiple sclerosis and autism and the possibility that they can cause diseases which thought

e-mail: fadia.ahmed@copharm.uobaghdad.edu.iq

to be vaccines associated[3]. Healthcare professionals' knowledge and attitudes toward vaccination can affect the patients' decision to vaccinate[4]. Misconceptions among healthcare workers may restrain vaccination process, since low level education and training about vaccination may lead to low rates of vaccination especially in people who are misinformed[5]. Pharmacists are able to take a fundamental responsibility in the vaccination administration to decrease vaccine-preventable deaths since they have a unique placement in community pharmacies with long working hours and being available on weekends[6]. It's more likely for patients to receive vaccines from educated and incited pharmacists rather than from a non-incited one [7]. The development of the practice zone of pharmacists as immunizers has encouraged adult vaccination by community pharmacies [8]. Still, reports from pharmacists about their needs to be well informed about the diseases and vaccinations so that they are able providerequired consultations and education to the parents and the patients[9].

As a result, it is vital to guarantee that pharmacists have the required updated knowledge regarding vaccination[4], and the pharmacy students as the future healthcare providers should have the necessary knowledge and attitudes toward vaccination, so it's possible for them to improve the information and conception of the parents so they can make the child vaccination decision[10]. This study is aimed to evaluate the knowledge and attitudes of pharmacy students toward vaccination.

Materials and Method

Study Design: A pilot study included a questionnaire according to literature[10]. The study instrument has been designed and validated by authors[10], and used in our study toexplore the knowledge and attitudes of pharmacy students toward vaccination. The questionnaire composed of two parts: The first one investigated the demographic data, such as gender, age, and family data which include parents' education and the number of pre-school children. The second part contained the attitude and knowledge survey which included five questions about the attitude and twenty questions about the knowledge. The questionnaire was administered (in English) to the fifth (final) and third year students in the College of Pharmacy/University of Baghdad during the academic year 2018/2019 in November and December/2018.

Ethics: The students participated in this study expressed voluntary approval to be included when they filled and returned the survey and they are all of age (older than 18). The questionnaire did not contain any personal identifiers during the distribution and collection process.

Statistics: The data was arranged and saved using Microsoft Excel. Frequencies and percents were used to describe categorical variables; these include the frequency of responses for the knowledge and attitude expressed as correct and wrong answers. Age and knowledge and attitudes score were presented as means and standard deviations (continuous variables). To calculate knowledge and attitudes' score, correct answers =1; wrong answers =0 values were used and the overall score for each student then the score for all students were calculated. The maximum score that can be obtained equals 25. Windows Statistical Package for the Social Sciences (SPSS) 20 has been used for advance data analysis. Continuous variables (age) have been analyzed by Man-Whitney test for non-parametric distribution, while the association between discrete variables (gender, parents' education, the siblings' number and preschool children's number) and the significance of differences in the knowledge and the attitudes' questions among the two groups have been analyzed by Chi square test for independence. P-values<0.05 were considered to be significant.

Results

A total of 277 students out of 330 completed the questionnaire (156 students out of 180 from the fifth grade and 121 students out of 150 from the third grade with response rate 86.7% and 80.7% respectively). The majority of students were females for both groups with a non significant difference between the two groups. The age range for the fifth grade was between 22 and 24 years with a mean age of (22.5±0.6) years old, while for the third grade was between 20 and 22 with mean age of (20.6±0.7) with a significant difference between them. The remaining variables are described in table (1), presented as numbers and percents with a non significant difference between the two groups. Mean knowledge and attitudes' score was 16.654 and 14.917 out of 25 for the fifth and the third grade respectively. The responses to the study questionnaire are presented in table (2). The knowledge and attitudes of the students are not influenced by parameters like father's education, mother's education, the number of siblings and

preschool children in the family (these parameters have no significant effect in determining the knowledge and attitudes of the students with P-value of 0.600, 0.355, 0.484 and 0.402 respectively).

Table 1: The students' demographic data.

	Parameter		**Fifth grade**	**Third grade**	**P-value**
1	Age: Mean ±SD		22.5±0.6	20.6±0.7	0.000

The responses are presented as numbers and percents.

Table 2: The knowledge and attitudes of Iraqi pharmacy students toward vaccination.

	Questions	**Fifth grade (n:156) Correct answers: n (%)**	**Third grade (n:121) Correct answers: n (%)**	**P-value**
1	Vaccine is a medical treatment contains killed or modified dangerous viruses and bacteria to be put into the body.	115 (73.72%)	97 (80.2%)	0.209
2	A disease causative agent that is killed or weakened is called active immunization.	128 (82.05%)	74 (61.2%)	<0.001
3	The antibody from person was infected with the disease is called passive immunization.	131 (83.97%)	69 (57%)	<0.001
4	The occurrence of any major infectious disease has not changed significantly by vaccines.	121 (77.56%)	93 (76.9%)	0.890
5	In fact, vaccines cause more disease than they prevent	135 (86.54%)	112 (92.6%)	0.110
6	Vaccines are from the most efficient and cheapest types of medical therapy.	109 (69.87%)	76 (62.8%)	0.216
7	Vaccines result in lifelong protection from many dangerous diseases; this explains why they are given for children on a regular basis.	140 (89.74%)	107 (88.4%)	0.727
8	Vaccination is for all age.	99 (63.46%)	71 (58.7%)	0.417
9	A feasible regular vaccination schedule should be started on the first day	99 (63.46%)	62 (51.2%)	0.041
10	Infants under 1 year of age should never receive vaccines.	82 (52.56%)	71 (58.7%)	0.310
11	More than 70% of vaccination doses are given for children younger than 2 years.	34 (21.79%)	21 (17.4%)	0.358
12	The first vaccination dose is BCG against Tuberculosis.	113 (72.44%)	83 (68.6%)	0.486

	Questions	Fifth grade (n:156) Correct answers: n (%)	Third grade (n:121) Correct answers: n (%)	P-value
13	The vaccine should not be freeze and their storage should be at a temperature above 8ºC.	94 (60.26%)	49 (40.5%)	0.001
14	After the seal is opened, the vaccine should be used within 72 hours.	65 (41.67%)	42 (34.7%)	0.238
15	Vaccines are harmful.	75 (48.08%)	53 (43.8%)	0.479
16	In case most of the population acquires protection against infections, the hazard of a few vaccines' adverse reactions is acceptable.	132 (84.62%)	76 (62.8%)	<0.001
17	One significant contraindication in child vaccination is fever.	103 (66.03%)	68 (56.2%)	0.095
18	It is more effective and safer for the child if given extra vaccination.	74 (47.44%)	38 (31.4%)	0.007
19	If vaccination dose was given to the child before the proper time, it will be repeated.	103 (66.03)	63 (52.1%)	0.019
20	The CDC (the Center for Disease Control and Prevention) recommends a yearly adult influenza vaccination.	54 (34.62%)	27 (22.3%)	0.026
21	Is it likely to have influenza as a result of the influenza vaccine?	73 (46.80%)	59 (48.8%)	0.745
22	The influenza vaccine is considered to be safe for children (with ages between 6 months and 18 years) and adults.	115 (73.72%)	79 (65.3%)	0.129
23	Vaccines are necessary	142 (91.02%)	114 (94.2%)	0.320
24	Are you in favor of vaccination in general?	126 (80.77%)	103 (85.1%)	0.342
25	Will you recommend vaccination to others?	136 (87.18%)	98 (81%)	0.158
	Mean knowledge and attitudes score	16.654	14.917	0.009

The responses are presented as numbers and percents.

Discussion

Overall, this study showed that the final year pharmacy students have positive attitudes toward vaccination with a non significant difference between fifth and third grade pharmacy students. According to the WHO immunization Strategic Advisory Group of Experts, the uncertainty about vaccination is largely growing and attitudes and viewpoints of health professionals are from the objective factors that determine it [(11)].

Many studies stated that positive attitudes of professionals in healthcare system have been realized to be associated with elevated vaccination rates [(12,13)]. Additionally, the recommendation of vaccines by healthcare professionals arises mainly from their belief that vaccines are beneficial and their professional obligation and requires patients´ trust in healthcare workers [(14)].

Other studies have shown that health professionals are considered a determinant factor for parents and other persons affecting themselves and their children's vaccination decisions[(15,16)]. Especially after the conflict against vaccination started a few years ago and resulted in hesitation and unwillingness of parents toward children's vaccination due to adverse effects and safety concerns[(17)], and claimed associations of vaccines to the occurrence of various diseases[(3)].

Healthcare professionals' vaccination knowledge can affect the vaccination decision, since badly informed caregivers may create obstacles against obtaining coverage of vaccination within a population [(4)]. Furthermore,enlightened and provoked patients by their pharmacist seem to be more likely to receive vaccines[(7)]. So, ensuring that health workers realize the facts, effectiveness and safety of vaccines is vitally important [(4)]. Opportunity to optimize and lead immunization preparation from the beginning of professional education can be obtained by evaluation of awareness, attitudes and concerns of students starting their health care professional study [(14)].

In our study, the students' knowledge and attitudes have not been affected by various parameters like parents' education, the number of siblings and preschool children in the family for both groups. One study showed that the knowledge about vaccination to be affected by the father education[10].

The first five questions investigated the general knowledge about vaccination and the responses in two questions about passive and active immunization were significantly different between fifth and third year students. This can be attributed to the fact that third year students did not receive the courses of Immunology and Public health yet, which are included in the fourth year syllabus in Iraqi pharmacy schools.

As progressing to more specific questions, correct answers' percentage decreased, with some questions having wrong answers in a higher percentage than right ones. When analyzing the questions investigated children's vaccination, most questions have been answered correctly by both groups with a non significant difference between them, except the questions which talked about that the children receive 70% of vaccination within the first two years of life and the safety of extra vaccination, the answers were mostly wrong in both groups. On the other hand, the question regarding the storage of vaccines has been answered mostly correct by fifth year students and wrong by third year students with a significant difference between them, while the questions related to the use of vaccine after its opening, and the CDC influenza vaccine recommendation for all adults, most answers were incorrect by both groups.

The overall knowledge and attitude score were significantly different between the two groups with both groups having a moderate score value and a higher score for fifth year students. These findings are compatible with another study which showed poor mean knowledge among medical field students [18]. This level of knowledge may create a negative attitude toward vaccination as a result of misinformed healthcare workers about vaccine function, aim and adverse effects [19].On the contrary, some studies demonstrated an elevated score of knowledge and attitude toward vaccination among students [20]. Another study stated that the knowledge and attitude score was high but has a non significant impact on vaccinations' acceptance [21].

In this study, the score can be linked to the fact that there is no specific course in the college curricula about vaccination and to inadequate structured exposure of the topic. Consequently, pharmacy students are partially uninformed of its significance, associated side effects, timetable, and storage. In general, there is low knowledge of the essential information about vaccination about their future responsibilities of pharmacist as a healthcare supplier. More than 35 colleges of pharmacy, including private and governmental pharmacy faculties in Iraq [22], all of them follow the same courses' outlines without a specific vaccinology course, and this represents a determinant factor in the pharmacy students' vaccination knowledge deficiency.

Many studies support this fact; a study conducted in the USA revealed that pharmacy schools have an obligation to enhance pharmacy student education and to develop the pharmacist-in-training skills that will prepare pharmacists for such a duty [5].Other studies reported the pharmacists' needs to acquire knowledge[9], and recommended to include a vaccinology course into the undergraduate syllabus of health care professionals in order to develop their knowledge[23]. Accordingly, the implication of a vaccinology course in the curriculum of pharmacy schools in Iraq can significantly increase pharmacists' knowledge and improve their attitudes toward vaccination.

On the other hand, a huge number of pharmacists graduate each year and the number of registered pharmacists at the Syndicate of Iraqi Pharmacists has exceeded the pharmacist to population ratio recommended by WHO (1:2000) [22]. This led to larger percents of unemployment in the private sector among young pharmacists, in addition to a disguised unemployment among pharmacists in governmental jobs with a limited role of the pharmacists in the hospitals and community health centers, and no role in vaccines' administration, since the Iraqi Ministry of Health does not implement pharmacy-based immunization services.

As a result, implementing pharmacy-based immunization program by the Ministry of Health can offer great benefits by utilizing the large number of pharmacists and provide additional job opportunities in the private sector. As many studies confirmed the readiness of pharmacy students to participate in the pharmacy-based immunization service [24], and the fact that pharmacists have a remarkable role as instructors, implementers and immunizers, by which they can promote patients to be vaccinated and to enhance vaccination rates[25]. Another study investigated the implementation the training

program of national immunization, in which a significant impact was reported on the demonstrated knowledge and expertise of the competent students. Nevertheless, the purported pharmacy students' attitudes did not vary considerably[26].

The limitations are small sample size included in our study and the fact that it is confined to students from the College of Pharmacy/University of Baghdad, since students from other pharmacy schools in Iraq may reveal different outcomes. Further larger scale research is required, with students from different pharmacy schools around the country, to obtain more precise and representing results.

Conclusion

In summary, this study showed a positive attitude toward vaccination among pharmacy students, which is considered to be a good result when taking into account the general misconception appeared in recent years. Both fifth and third year students demonstrated an intermediate level of vaccination knowledge with significant difference and more score for fifth year students over third year students.

The addition of a specialized vaccinology course to the curriculum in pharmacy schools can improve their knowledge and attitudes. Furthermore, implementing the pharmacy-based immunization program by the health authorities can improve the future role of pharmacists in the healthcare system and help to utilize the increased numbers of pharmacists in Iraq.

Trend of Implementation Foster Family Toddlers (FFT) Programin East Java Province at 2015-2019

Fadilatul Fahmiyah[1], Lutfi Agus Salim[2]

[1]Bachelor Student in Department Biostatistics and Demography, Faculty of Public Health, Universitas Airlangga, Surabaya, Indonesia, [2]Associate Professor in Department Biostatistics and Demography, Faculty of Public Health, Universitas Airlangga, Surabaya, Indonesia

Abstract

Foster Family Toddlers (FFT) as an effort program to improve the knowledge and skills of parents fostering the development of children in a whole and optimal way. The result of 2018 Basic Health Research, East Java Province shows the percentage low birth weight is 6.5%, underweight of toddler is 15%, wasting of toddler is 8% and the coverage of exclusive breast milk is 40%. East Java Health Profile 2018 showed of low birth weight is 3,7% and the coverage of exclusive breast is 76.83%, underweight and wasting in toddler is not found numbers, but there is the weight of toddler in under red line is 0.77%. Therefore, needs to know trend of the implementation of FFT in East Java. This study was quantitative descriptive research design with secondary data. The result showed the reporting of FFT group from 2015-2017 increased by 4.52% and decreased in 2017-2019 by 4.52% and has not reached the target of KKP 80%. FFT member participation in 2015-2017 increased by 3.78% and decreased in 2017-2019 by 12.55%. FFT family attendance at the 2015-2016 Meeting increased by 1.38% and decreased in 2016-2019 by 1.24%, and the family of members of FFT Child Card Users in 2015-2019 saw a continuous increase of 9.52%. So the result of the trend of the implementation of activities is less maximal because there are still some obstacles to be considered.

Keywords: *Foster Family Toddlers, child growth, chart reporting.*

Introduction

Family development is an effort to realize quality families who live in a healthy environment through family development. Family development is the responsibility of all parties including NPFP as mandated in Law No. 52 of 2009 on Population Development and Family Development[(1)]. Family development policies are carried out through fostering resilience and family welfare[(2)]. One of them is implemented through improving the quality of children by providing access to information, education, counselling and services on care, parenting and child development to families with toddlers. Children are a valuable investment in the progress of a nation because the child is the future holder of the nation, therefore the child as a Human Resources (HR) must be built early on in order to create quality human resources for the future of the nation[(3)].

Optimal growth and development is one of the rights of every child stipulated in Law No. 23 of 2002 on Child Protection article 26 items a and b. Under the Law, parents are obliged to nurture and develop children. This is the same as the rights of the child described in the Convention on the Rights of the Child. Based on this it is clear that optimal growth is the right of every child and should be obtained by the child. The realization of the goal is not separated from the role of parents as the child's first environment[(4)].

The Ministry of National Development Planning noted that during 2018-2019 East Java Province is one of the provinces that is the priority area of stunting problem

e-mail: lutfi.as@fkm.unair.ac.id

handlers. In 2018, East Java has 11 locus for stunting (including Jember Regency, Nganjuk Regency and Lamongan Regency), and in 2019 increased by 1 district, namely Kediri Regency[5].Basic health research data in 2018 shows that there is a decrease in stunting rates compared to 2013, stunting rates in East Java are still at more than 30%. 2018 Basic Health Research results, East Java Province the numbers are as follows: Underweight percentage of 6.5%; underweight prevalence in toddlers by 15%; the prevalence of wasting in toddlers is 8% and exclusive breast milk coverage is 40%[6]. East Java Health Profile 2018 the percentage ofunderweightwas 3.7%; and exclusive breast milk coverage of 76.83%, for indicators of prevalence of underweight and wasting in toddlers there is no figure, however there is data that the figure of toddlers weight below the red line is 0.77%[7].

Recognizing the importance of fostering children's development early on, since 1984 the National Population and Family Planning Board (NPFP) established the Toddler Family Development Program (FFT), and since 1991 this program has developed into the FFT Movement. FFT implementation is an effort to improve the knowledge and skills of parents in fostering the development of children in a whole and optimal way, through the provision of physical, cognitive, socio, emotional and spiritual stimulation. By actively participating in FFT activities, parents are expected to have enough supplies to help their children live their toddler life properly, well and pleasantly [8]. Therefore, researchers are determined to study how the trend of implementing FFT activities in East Java Province in 2015-2019.

Method

This research was used quantitative research method with quantitative descriptive research designs. The data source is used secondary data. This study uses data sourced from the NPFPyearly report and also the policy for the implementation of the NPFP FFT Program.

Results

Implementation of FFT are activities that are carried out once a month. To perform its functions properly. The implementers of the FFT program in the field are trained cadres, while participants or members of the FFT group are parents and other family members who have toddlers (0-5 years) and preschool age (5-6 years) [9]. The formation of FFT Group is carried out as a family coaching platform to improve knowledge and skills in parenting and fostering children. The development of FFT group is carried out as an effort to improve the quality and quantity of the group through cooperation with related partners in both the government and private sectors. One form of development is the integrated FFT-integrated service post (POSYANDU)-PAUD (health, education) and the formation of FFT pilot groups in each sub-district[10].

The recording and reporting in the Resilience Program for Children and Toddlers is carried out in a tiered way starting from the implementation of activities by FFT groups at the field level, villages, sub-districts, districts/cities, provinces and national. The recording and reporting of FFT activities is carried out by FFT cadres, including[11]:

1. FFT group registration card (K/0/FFT/10)
2. FFT group record card (C/1/FFT/10)
3. FFT report card (R/1/FFT/10)
4. Activity notebooks include: attendance/registration books, records of activity implementation, work plans, ledgers, and participation notes of kb members.

Based on the chart above, shows that the trend from 2015-2017 increased by 4.52% which in 2015 the existing FFT group was 13,809 and which reported a total of 13,121 which means its achievement of 95.02%, then in 2016 the existing FFT group numbered 15,052 and which reported a total of 14,549 which meant its achievement amounted to 96.66% and also in 2017 the existing FFT group numbered 14,912 and which reported a total of 14,843 which meant its achievement of 99.54%. However, there was a decrease in 2017-2019 of 31, 32% where in 2018 the existing FFT group amounted to 14,984 and which reported a total of 14,473 which meant its achievement amounted to 96.59%, then in 2019 the existing FFT group amounted to 21,925 and which reported a total of 14,311 which means its branding of 65.27%. This is because the target of the toddler's family who have to follow the FFT increases.

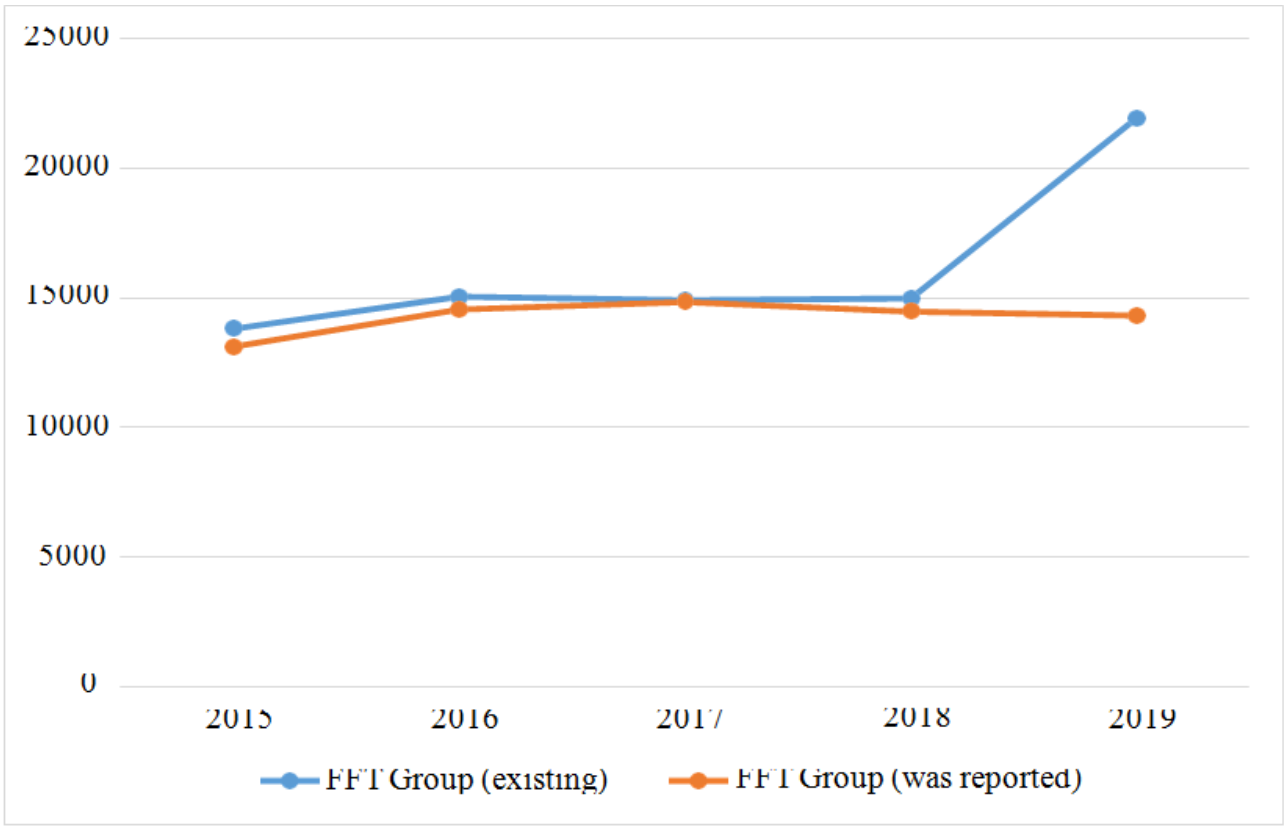

Figure 1 FFT Group Reporting Trends in East Java Year 2015-2019

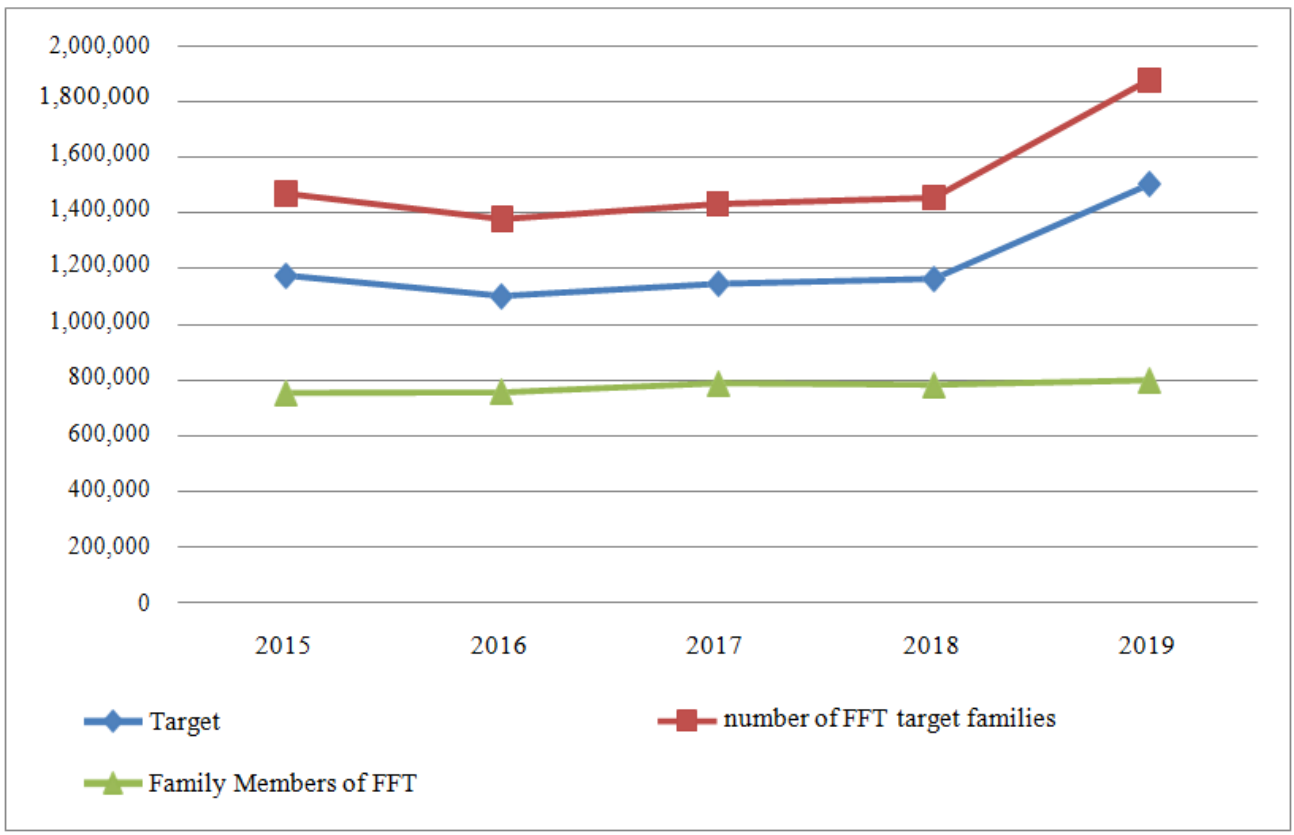

Figure 2 Trends of FFT Member Participation in East Java Year 2015-2019

The results of the analysis showed that the trend from 2015-2017 increased by 3.78% where in 2015 the number of FFT target families was 1,470,022 and that FFT members total 754,998 which means the achievement of 51.36%, then in 2016 the number of FFT target families is 1,378,877 and who are members of FFT number 757,142 which means its achievement of 54.91% and also in 2017 the number of FFT target families is 1,432,658 and which is a member of FFT number 789,918 which means its achievement of 55.14%. If seen from the target of KKP that is 80% per year, then FFT membership has not reached the target of 2015 (1,176,018), 2016 (1,103,102), and 2017 (1,146,126).

The trend of achievement decreased in 2017-2019 by 12.55% where in 2018 the number of FFT target families was 1,454,885 and that became a member of FFT a total of 784,004 which means its achievement of 53.89%, then in 2019 the number of FFT target families was 1,879,051 and who became a member of FFT numbered 800,378 which means its achievement of 42.59%. If seen from the target of KKP that is 80% per year, then FFT membership has not reached the target of 2018 (1,163,908), and in 2019 (1,503,241). The surge in family participation trends following FFT can be due to the declining number of coaches in the field, people tend to have less interest in finding knowledge and parenting skills through FFT and start relying on gadgets to find knowledge.

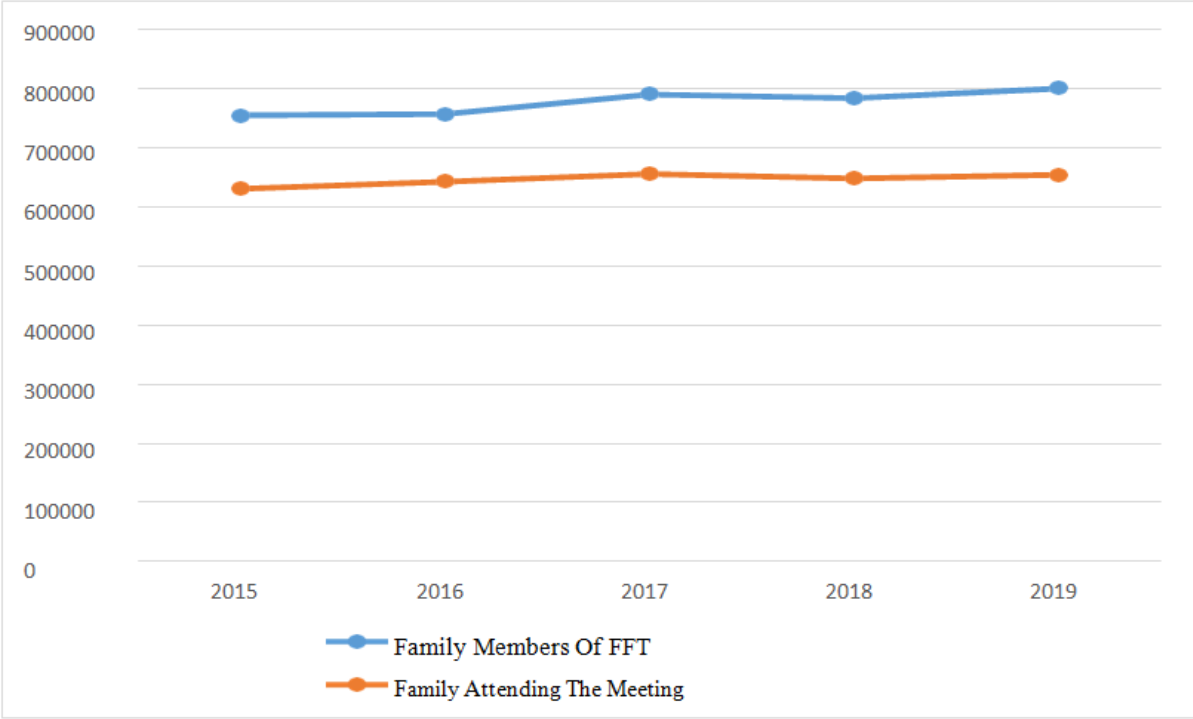

Figure 3 Trends of FFT Family Attendance in East Java Meeting 2015-2019

Based on the chart, showing that the trend from 2015-2016 increased by 1.38% where in 2015 families attended the meeting as many as 630,963 of the families who were members of the FFT as much as 754,998 which meant the achievement of 83.57%, then in 2016 the family attended the meeting as many as 642,762 of the families who became members of FFT as much as 757,142 which means its achievement amounted to 84.89%.However, there was a decrease in 2016-2019 of 1.24% where in 2017 the family attended the meeting as many as 655,862 of the families who became members of FFT as much as 789,918 which meant the achievement was 83.03%, in 2018 the family attended the meeting of 648,325 of the families who became members of FFT as many as 784,004 which means the achievement of 82.69%, then in 2019 the family attended the meeting as many as 654,633 of the families who became members of FFT as much as 800,378 which means the achievement of 81.79%.

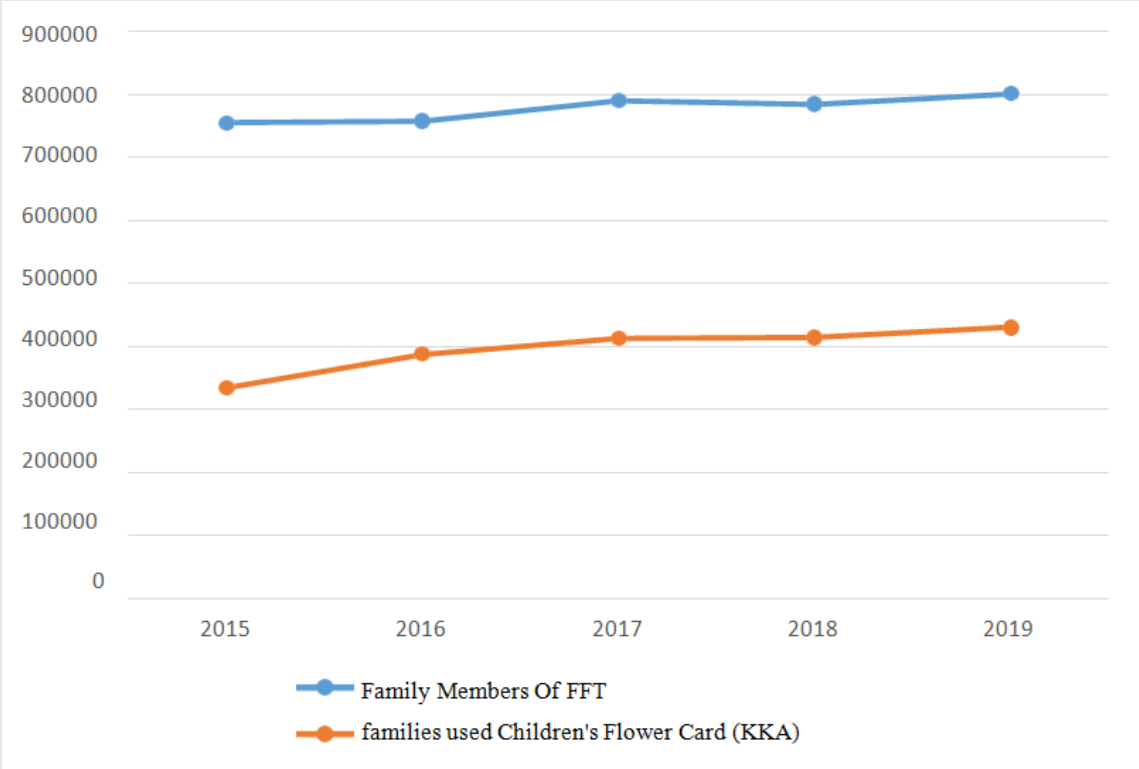

Figure 4 Trends of Family Members of FFT Using KKA in East Java in 2015-2019

Based on the chart, showing that the trend from 2015-2019 increased continuously by 9.52% where in 2015 FFT member families used Children's Flower Card (KKA) by 334,341 of the families who became FFT members as much as 754,998 which means its achievement of 44.28%, then in 2016 the family of FFT members used KKA as much as 387,288 from families who became members of FFT as much as 757,142 which means its achievement of 51.15% , in 2017 the family of FFT members used KKA as much as 413,041 from families who became members of FFT as much as 789,918 which means its achievement of 52.29%, in 2018, the family of FFT members used KKA as much as 414,207 from families who became members of FFT as much as 784,004 which means its achievement of 52.83%, and in 2019 the family of FFT members used KKA as much as 430,575 from families who became members of FFT as much as 800,378 which means its achievement of 53.80%.

Discussion

The government has made various efforts to improve the quality of human resources, among others through the Integrative Holistic Early Childhood Development Program. This program is strengthened by Presidential Regulation No. 60/2013 on Integrative Holistic Early Childhood Development. With the implementation of holistic integrative early childhood development, it is hoped that the essential needs of early childhood in its entirety including health and nutrition, stimulation of education, moral-emotional coaching, and parenting can be met[12].

The National Family Planning and Population Board (NPFP) also plays a role in the implementation of integrative holistic early childhood development through the Toddler Family Development (FFT) activity group. Integrative holistic early childhood development is carried out in FFT, early childhood education program Post, and integrated service post-groups. The FFT group improves the knowledge of parents and families who have toddlers regarding parenting; early childhood education program Post provides educational services to early childhood; while integrated service post provides health services for early childhood. Some of the obstacles found in the implementation of FFT, include[13]:

1. Limited number of FFT cadres, due to difficulty regeneration of workers and lack of operational support, among others: fee, etc.

2. Limited number of Family Planning Counselors (PKB) handling in the field.
3. FFT cadres who are concurrent as integrated service post cadres so that the implementation of FFT activities does not optimal.
4. Number of cadres, because between the number of cadres and the number of participants is not balanced
5. Inefficient time utilization is also a factor in inhibiting FFT program.

The pattern of child care is also inseparable from the culture of child play. In developmental psychology literature, children aged 0-6 are "good impersonators" and "tenacious learners", but not a "good listener"(14). Children of this age will be easier to learn and understand by doing activities, not by being told or just words. Therefore, early childhood requires play activity to stimulate nerve development. According to Freud and Erikson playing for a child is very useful as a form of self-adjustment, helping the child master the anxieties and conflicts it faces(3). The game is believed to be able to relieve tension so as to help the child in solving problems and conflicts faced in his life. To realize the above, it is necessary to create a meaningful learning environment for early childhood, among others through a variety of meaningful games that are able to provide comfort for the child in learning and the right stimulation will be realized(15).

Conclusion

The implementation of the Family Resilience Program of Toddlers and Children is outlined in the Operational Guide to the Implementation of The Resilience Program of Toddlers and Children namely the development of operational policies and strategies, formation and development of FFT groups, the development and provision of FFT Kit facilities, socialization, coaching, monitoring and evaluation of coaching and recording and reporting. FFT Group Reporting Chart shows the trend from 2015-2017 increased by 4.52% but decreased in 2017-2019 by 31.32%. However, if you look at the target of KKP 80%, then the results have not reached the target. FFT Member Participation Chart shows that the trend from 2015-2017 increased by 3.78% but decreased in 2017-2019 by 12.55%. The FFT Family Attendance graph in the Meeting shows that the trend from 2015-2016 increased by 1.38% but decreased in 2016-2019 by 1.24%, and the KKA User FFT Member Family chart shows that the trend from 2015-2019 increased continuously by 9.52%. Although the result of the trend has decreased or increased, in the implementation of activities there are still some obstacles to be considered.

Recommendation:

1. Improving institutional strengthening with integrative systems and efforts to prepare aspects of legitimacy such as decision letter (SK), implementation guidelines, technical instructions and so on.
2. Improving commitment, coordination and cooperation with relevant partners, stakeholders and with communities/associations/organizations related to FFT group organizing

Abstract

Objectives: To assess the knowledge of patients with acute renal failure concerning dietary pattern for kidney failure in dialysis unite in AL-Zahraa Teaching Hospital at AL-Kut City and Find out relationship between demographic data and knowledge of patient with acute kidney failure. By a non- probability sample account of (30) subjects is selected for the purpose of the present study. A questionnaire as a incomes for data gathering, it consist of two parts; include demographic data and knowledge of patients with acute renal failure concerning dietary pattern which composed of (18) items. By self-administration, data are collected from those who patients with renal failure come in dialysis unite in AL-Zahraa Teaching Hospital and analyzed through the used descriptive and inferential statistic approach. The study results indicated that the most of the participants are within married (60%), and most of them are male. In regarding level of education, they most of them formally graduation, and administrative patients, as well the subjects have chronic disease such as diabetes mellitus and find statistical high significant between level of education and knowledge of patient at p-value <0.05 with non-significant between other demographical data

Keywords: *Assessment, renal failure, dietary pattern.*

Introduction

Acute kidney failure (AKF) is a disorder in which of therenal are incapable to eliminate waste the crops of breakdown. The disappointment of kidney purpose is quick in its start but possibly reversible. It happens speedily, within 8 wks of kidney damage subsequent in a fastrise in serum urea and creatinine courtesies in patients with beforehand standard kidney purpose[(1)].It is a disorder usually associated with a high humanity rate, often due to the glitches of sepsis, latecoiled healing and troubledhaemocoagulation. Survivability has been recognized to be better by early suitable nutritional support[(2)]. Although in repetition this is often problematic to achieve as nutritional support is multifaceted. In the past high disease and humanity rates were connected to infections and inadequate dietary intake. This resulted from unnecessary protein restrictions in an attempt to control uremicindications[(3)]. To a large degree survivability of acute renal failure has still not been prominently improved even with contemporary antibiotics and the careful nourishing valuation of acute renal disappointment patients. This reflects the difficulty of managing patients with this disorder. Though, appropriate nutritional management of ARF patients is essential to recover their long-term forecast[(4)]. Although the precise form this takes remains a contentious issue between clinicians. The nourishment of kidney patients varies and their effect on the progress of the patient's disorder according to the stage in which the illness has been industrialized, we find that nutrition has a protective role and mitigation of the following symptoms if the kidney failure in the early stage.[(5)] Should decrease the quantity of protein, as Urea is the

creation produced by the breakdown of proteins in the body and upsurge the volume of protein in the body leads to increased effect on the kidneys, and consequently it is recommended to decrease the amount of protein in the diet rendering to the patient's condition.

Methodology

Study Objectives: To assess the knowledge of patients' with acute renal failure concerning dietary pattern for kidney failure in dialysis unite in AL-Zahraa Teaching Hospital at AL-Kut City

Find out relationship between demographic data and knowledge of patient with acute renal failure about dietary pattern

Study design :A descriptive study, using assessment method, is carried out to assess the knowledge of patients' with acute renal failure concerning dietary pattern for kidney failure in dialysis unite for AL-Zahraa Teaching Hospital at AL-Kut City. A non-probability simple random account of (30) patients who comes for dialysis. A questionnaire as resources of data collection was constructed for the purpose of study. It consisted from two parts, include:

Part I: This part contains demographical data which include (gender, address, marital status, level of education, chronic disease, and period of diagnosis).

Part II:this part about knowledge of patients with ARF concerning dietary pattern which composed from (18) items and answered on the question by Yes, or No, take time for each one (10-15) minute

Data analysis: Complete the used descriptive statistical (SPSS) form(21) analysis tactic that includes, frequencies, percentages, cruel of scores, standard divagation and graphical presentation of data; and inferential statistical data analysis approach that comprise ANOVA test.

Result and Discussion

Results signify the distribution of the patients' demographic items in term of frequencies and percentage. The **Table (1)** statistical analysis find patient with renal failure specific acute kidney failure have low level of knowledge concerning dietary pattern except questions (4, 5, 6, 7, 11.15, 16, 17) due to mean score for this results in high level (1.81-2) these result agree with [6] them study knowledge on dietary group among long-lasting renal disappointment patients experiencing hemodialysis at selected hospital, Kanchipuram. And find patient with chronic renal failure have knowledge deficiency concerning dietary management for renal failure and disagree with [7] he which studythat Assessment of the effectiveness of structured teaching package on knowledge regarding nutritionalorganization and casing care in renal failure among patients experiencing hemodialysis and find high level of knowledge for patients with chronic renal failure toward nutrition management. Regarding **Table (3)** this table shows that there is statistical significant association between patient' educational level and their knowledge concerning dietary pattern for renal failure (p value < 0.05) when analyzed by ANOVA. There is No statistical significant association between nurses' (other demographic data) and their knowledge concerning dietary pattern for renal failure and agreement with [8] A study to assess the knowledge and practice regarding dietary management of patients from rural area with end stage of renal disease undergoing hemodialysis in a selected hospital at Mysore. Find connection between patient knowledge and practice regarding nutrition management for end stage renal disease and level of education. Disagreement with[8] he study is Aevocative study to assess the information on dietary running among chronic renal dissatisfaction patients undergoing hemodialysis, he find non-significant between knowledge of patients with chronic renal failure [9,10].

Table (1): Distribution patient with acute renal failure knowledge concerning dietary pattern for kidney failure in dialysis unite

N	Variables	Yes answer		No answer		M.S	Ass.
		f	%	f	%		
1	Did you know that renal insufficiency is a term used in the case of failure of the kidneys to perform its functions	13	44.0	17	56.0	1.57	L
2	Did you know that urea is the toxins in the body that are thrown through the kidneys	12	40.0	18	60.0	1.60	L

N	Variables	Yes answer		No answer		M.S	Ass.
		f	%	f	%		
3	Did you know that the main symptoms of acute kidney failure are lack of urination, body buildup and high blood pressure	10	24.0	20	66.0	1.67	M
4	Did you know that dialysis is not a cure for renal failure, but is to reduce the toxins in the body and the transplant is the ultimate treatment	6	20.0	26	80.0	1.80	M
5	Did you know that adherence to a healthy diet reduces the damage of kidneys, especially patients with acute renal failure?	5	16.0	25	84.0	1.83	H
6	Did you know that the diet for patients with renal failure differs from the diet of healthy people	4	13.0	26	87.0	1.87	H
7	Did you know that diet is an important part of the treatment plan and to develop a diet suitable for the patient of renal failure in accordance with the health status of the patient	9	30.0	21	70.0	1.87	H
8	Do you avoid foods that contain high water content such as soup, grapes, watermelon, lettuce, tomatoes, celery	13	44.0	17	56.0	1.57	L
9	Do you avoid salty foods that increase your drinking water?	6	20.0	24	80.0	1.80	M
10	Do you avoid foods that contain vitamin A? Now it increases the calcium and fat deposits in the body	7	23.0	23	77.0	1.80	M
11	An increase in salt intake causes fluid retention, so sodium should be reduced in the diet because it helps control high blood pressure and prevents the body from holding fluids.	3	10.0	27	90.0	1.91	H
12	Reduces phosphorus-containing foods such as milk, meat, poultry, nuts and pulses because the increase in phosphorus leads to a lack of calcium in the body, leading to a lack of bone building	6	20.0	24	80.0	1.80	M
13	Did you know eating large amounts of milk, vegetables and fish increases the amount of calcium that your body needs to build muscle	17	56.0	13	44.0	1.77	M
14	Did you know that increasing the rate of potassium in the body is a danger should avoid some foods such as potatoes, banana, apricot, orange, kiwi and dried fruits such as raisins	6	20.0	24	60.0	1.80	M
15	You take the appropriate water of protein useful for the body was found in white meat	2	7.0	28	93.0	1.93	H
16	Avoid foods that contain spices, especially canned foods, because they contain sodium salts that build up fluids in the cells of the body	5	16.0	25	84.0	18.3	H
17	Avoid protein from nuts, seeds, peanut butter, dried peas, beans, and lentils because they contain a high percentage of potassium and harmful calcium to the body	3	10.0	27	90.0	1.91	H
18	Exercise with adherence to diet reduces kidney damage	4	13.0	26	87.0	1.87	H

F: Frequency, P: Percentage, M.S: Mean of score, Asses = Assessment level, low (1-1.60) = L, moderate (1.61-1.80) = M, high (1.81-2) = H

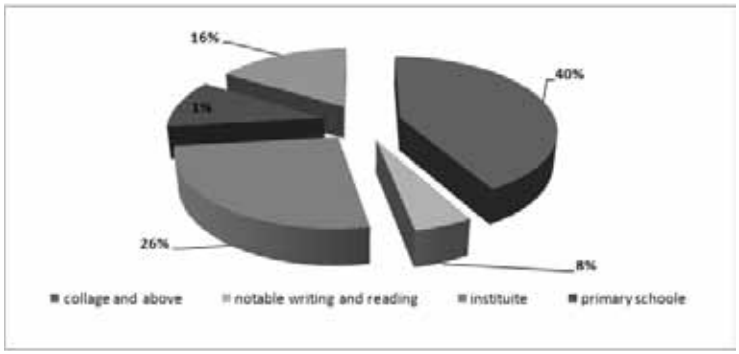

Figure (1) Show distribution between level of education for patient' with acute renal failure and knowledge about dietary pattern

Table (2): Relationship between demographical data and knowledge of patient concerning dietary pattern

Level of education / Knowledge of patients	M.S.+S.D.
Notable read and write	1.25 + 0.442
Able to read and write	1.31+0.471
Primary school	1.28+0.458
Secondary school	1.36+0.488
Institute	1.50+0.511
Collage and above	1.44+ 0.506

*F: 1.088 *d.f.: 2 *p. value : 0.346

Conclusion

The study concludes that more of the patients who come to dialysis unit in AL-Zahraa Teaching Hospital in AL-Kut City have low level of knowledge concerning dietary pattern that related to renal failure specific patients characterized by short period of diagnosis and low level of education

Recommendation: Study recommendation is established education program for teaching and increase patients knowledge concerning dietary pattern for renal failure and makes vide and poster with booklets which includes definitions the renal failure and nutrition management for kidney failure

Ethical Clearance: Permission from dialysis unite, in Al-Zahraa directorate was attained before starting the study. All the participants gave verbal consent with confidentiality of participants' identification

Assessment of Women's Knowledge and Practices toward Family Planning at Maternity Hospitals in Baghdad City

Fatima Fadel Benyian

Assistant Instructor, Maternal and Neonatal Nursing Department, College of Nursing, University of Baghdad

Abstract

Family planning is the decision that couples make about if they want to have children, when, how many children, and how they are spaced. Knowledge is necessary to make decisions and know how to avoid conception. Some couple needs counseling because contraception has failed.

Objectives: To assess women's knowledge and practices about family planning and find out the association between women's knowledge and practices with some study variables.

Method: Descriptive study was conducted from October 2019 to March 2020 at maternity hospitals in Baghdad city. Non probability (purposive sample) was used to collect the data from (79) women who attending outpatient clinics at maternity hospitals in Baghdad city. A questionnaire was designed by the researcher. A pilot-test is conducted in order to determine the reliability of the questionnaire in a sample of (20) women who were excluded from the study sample. Data was analyzed through the use of SPSS version 20.

Results: The results revealed that the highest percentage (49.4%) of women's age was (30-39) years. More than two third of them (69.6%) are graduated from college. The higher percentages (63.3) have knowledge and (58.2%) used a family planning method. There are no statistical significant differences between women's knowledge and practice.

Conclusion: This study finds that the women have knowledge and used a family planning method, but there are no significant differences between women's knowledge and practices.

Recommendations: Based on study findings the source of knowledge from the internet and they choose a type of family planning based on family and friends advice so the researcher recommend to activate the role of health care professional especially doctors and nurses to provide scientific knowledge and counseling to couples to choose the most appropriate method.

Keywords: *Knowledge, Practices, Family Planning Method, Women.*

Introduction

Family planning is so important that many national health goals speak directly to this area of care. Intentional pregnancy is important for a child's health, because unintended or misused pregnancy leads to short-term and long-term consequences such as a low rate of antenatal care visit, breastfeeding, and may be less eager to protect her fetus from harmful substances. A child of unintended pregnancy is at greater risk of low birth weight, dies in the first year, being abused, and does not receive sufficient resources for healthy growth and development[1].

Having children is one of the most important roles and performance of a woman, however, for a physiological process; pregnancy is an unexpected, unpleasant, unplanned and high risk and can cause disability and death[2].

Family planning deals with the woman's reproductive health, adequate birth spacing, avoiding

unwanted pregnancies and abortions, preventing sexually transmitted diseases, and improving the quality of life of the mother, fetus and family as a whole[3].

A woman's decision to use family planning method and choosing the method are affected by several complex psychosocial and structural factors, including contraceptive beliefs, negotiation ability with partner about using a contraceptive method, and access to services of reproductive health. Knowledge is an important factor that affects decision making for using a contraceptive method[4].

Globally, perinatal mortality about (40%) of infant mortality yearly, resulting in about three million stillbirths and four million neonatal deaths. Perinatal mortality rate is high in low-income countries, with an average (50 deaths/1000 live births), compared with (ten deaths/1000 live births) in high-income countries. Family planning has been shown that reduce maternal and infant mortality, however contraceptive use in many resource-limited countries [5].

Family Planning services in Iraq need more efforts to be improved, as the indicators include: Modern Contraceptive Prevalence Rate (28%), unmet needs (22%), Adolescents Birth Rate (60%), and unwanted pregnancies (12%). Total Fertility Rate is (4.6) live births per woman and population growth Rate three percent. From above, it's clear that indicators negatively affecting the women and family health and also the development plans[6].

Materials and Method

Descriptive analytic study design was conducted among women attending outpatient clinics at maternity hospitals to assess their knowledge and practices about family planning. The study was performed from October 2019 to March 2020 at maternity hospitals in Baghdad city. Non probability (purposive sample) used to collect the data from (79) women. A questionnaire was designed by the researcher to assess women's knowledge and practices about family planning. A pilot study conducted in order to determine the reliability of the questionnaire in a sample of (20) women who excluded from the study sample (r1= 0.85). Content validity was determined through a panel of (8) experts their experience mean and SD was 26.6±5.5. The data was collected after obtaining the agreement from women to participant in this study. The study instrument was consisted of three parts which include: Socio demographic characteristics, women's knowledge about family planning and women's practices about family planning. Data are analyzed through the use of SPSS (Statistical Process for Social Sciences) version 20.

Results

Table (1): Distribution of Study Sample According to Socio-demographic Characteristics

Socio Demographic Characteristics	F	%
Age/years		
< 20	1	1.3
20-29	21	26.6
30-39	39	49.4
40-49	18	22.8
Total	**79**	**100**
Mean=33.94 SD=6.2		
Duration of marriage/years		
1-5	23	29.1
6-10	34	43.0
11-15	11	13.9
16-20	7	8.9
> 21	4	5.1
Total	**79**	**100**
Mean=8.7 SD=5.7		
Age of last child/years		
1-4	63	79.7
5-8	11	13.9
9-12	5	6.3
Total	**79**	**100**
Mean=4.3 SD=7.1		
Educational level		
Secondary School	6	7.6
Institute graduate	17	21.5
College graduate	55	69.6
Master and higher	1	1.3
Total	**79**	**100**

This table illustrates that the highest percentage (49.4%) of women's age were (30-39) years. Regarding duration of marriage the higher percentage (43%) of them were (6-10) years. Regarding educational level more than half of them (69.6%) were graduated from college.

Table (2) Women's Knowledge about Family Planning Method

No.	Item	Know		Don't know		MS	RS	Ass
		F	%	F	%			
A	**Family planning method**							
1	Complex Contraceptive Pills	62	78.5	17	21.5	1.78	89	H
2	Mini Pills	33	41.8	46	58.2	1.41	70.5	L
3	Types of Contraceptive Injection	34	43	45	57	1.43	71.5	L
4	Intrauterine devices	44	55.7	35	44.3	1.55	77.5	M
5	Male Condom	52	65.8	27	34.2	1.65	82.5	M
6	Female condom	45	57	34	43	1.56	78	L

8	Vasectomy	52	65.8	27	34.2	1.65	82.5	M
B	**Ideal pregnancies spacing**	36	45.6	43	54.4	1.45	72.5	L
	Total	**50**	**63.3**	**29**	**36.7**	**1.63**	**81.5**	**M**

(M.S) mean score (R.S) relative sufficiency (Ass.) assessment (Low= ≥ 75), (Moderate= 75.1-87.5), (High= 87.6-100)

This table shows that there are a low level of relative sufficiency and mean score regarding items No.(2,3), while there are a high level of relative sufficiency and mean score regarding items No. (1). Also there are a low level of relative sufficiency and mean score regarding items No. (B). Also the total knowledge relative sufficiency and mean score is moderate level.

Table (3) Women's Sources of Knowledge about Family Planning Method

No.	Item	F	%
1	Doctor	16	20.3
2	Nurse	2	2.5
3	Internet media	27	34.2
4	Experience	4	5
5	Reading	12	15.2
6	Friend and Family	18	22.8
	Total	**79**	**100**

This table illustrates that the highest percentage (34.2%) of women's sources of knowledge were from the internet and media.

Table (4) Women's Practices toward Family Planning Method

No.	Item	F	%
A	**Type of family planning**		
1	Natural Family planning method	4	5.1
2	Contraceptive Pills	7	8.9
4	Injection	1	1.3
5	Intrauterine devices	19	24.1
6	Male Condom	13	16.5
7	Female condom	1	1.3
8	Tubal Ligation	1	1.3
	Didn't use	33	41.8
B	**Women choose type based on**		
1	Doctor	11	10.1
2	Couple	7	8.9
3	Experience	1	1.3
5	Family and Friends	27	34.2
6	Didn't use	33	41.8
	Total	79	100

This table shows the highest percentage (24.2%) of women who used a family planning chooses Intrauterine devices, and their choice was based on Family and Friends.

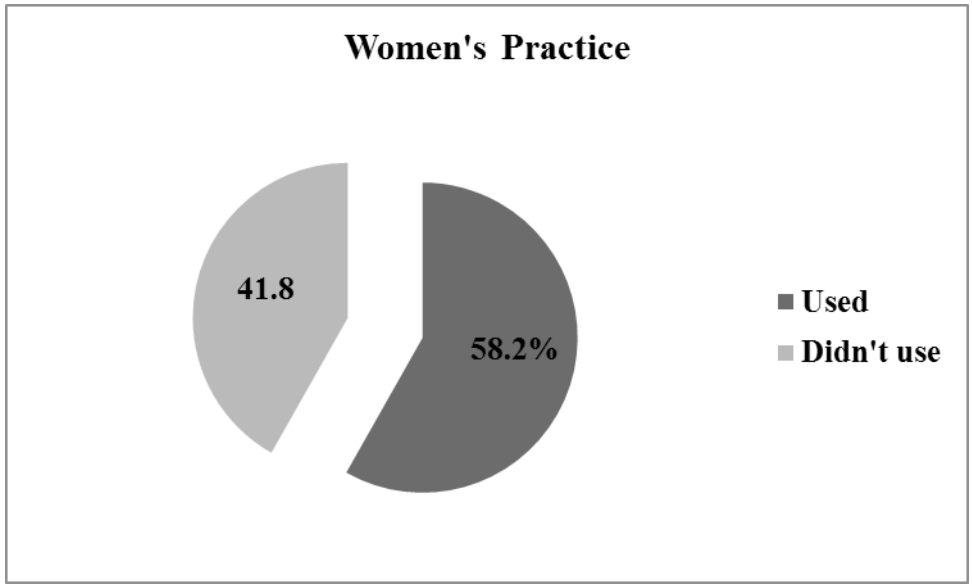

Figure (1) Women's Practice toward Family Planning Method

Table (5): Association between Women's Knowledge and Practices with Socio-Demographic Variables

(df) degree of freedom, (Sig) significant Probability value ($P < 0.05$), (NS) Non Significant, (s) significant.

This table shows that there are no statistical significant between women's knowledge and practice with socio-demographic variables toward family planning method

Discussion

The findings of current study show about half of women's age were (30-39) years, more than one third married for (6-10) years, their last child's age was (1-4 years). Regarding educational level more than two third was graduated from college.

Agha and Rasheed stated that Iraq, like some other developing countries, people have still appreciates early marriage, large families and a role for woman in the home. In addition, the previous Iraqi government, especially in the 1980s, encouraged high fertility to compensate for casualties during its wars. Until the middle of the past decade, the Iraqi Ministry of Health neglected family planning in the country. This explains why the crude birth rate in Iraq was one of the highest in the world in the late 1980s and early 1990s . At the time of their study, health services in Iraq, including family planning, were almost free in government clinics, when these were available, but not all family planning method were available in family planning clinics. Therefore, for many mothers, the sources of family planning services were private clinics and pharmacies due to the limited services[7].

The current study found more than half of study sample have knowledge about family planning method, while they didn't know the ideal pregnancies spacing. This might be due to most of the study sample were graduate from college so they think in family planning are useful to be economically, self-sufficient and more likely to acquire greater confidence and personal control in marital relationships including the discussion of family size and contraceptive use. More than third of their source of knowledge were from the internet, and second higher percent from family and friends. This finding supported with a study who found more than third (42.3%) of study participants had good knowledge, and (50.4%) had good practice towards family planning[3]. another study reported that the higher percentage (45%) of the women's source of information was from media, followed by (15%) from internet/friends and relatives and ten percent from health professionals. This study finding also is consistent with a study who found (70%) had gained knowledge of contraception from friends and relatives and (39%) from TV and radio[9-10].

Women's decision making to use contraceptive method is affected by many factors including knowledge gained from various sources. Blackstock and collegues found that the role of the social network regarding family planning generally to provide women contraceptive information and particularly to guide women to a specific contraceptive method. They found that the knowledge gained from health care providers especially social network members often enhanced or clarified their knowledge gained from other informal sources, [4].

This study found more than half of study participant were use a family planning method, they choose intrauterine device and male condom as a higher percent. They choose the method based on advice from their family and friends.

The condom use was high rate compared to neighboring countries; this may be due to the free availability of condoms in Dohuk. However, similar rates of condom use have been reported in Iraq and the Islamic Republic of Iran and among Palestinian refugees[7].

Many women want to delay pregnancy and avoid STIs, as options are difficult. There are many method available today, and more will be offered in the near future. The ideal method of contraception for many women should have the following characteristics: ease of use, safety, efficacy, minimal side effects, "nature", non-hormonal method, and immediate reversal. Currently, no single method of contraception offers everything [8].

Conclusion

This study revealed that more than half of study sample have knowledge about family planning method and they used a family planning method. The most common type of family planning was intra uterine device. There are no statistical significant differences between level of knowledge and women's age or educational level. There are no statistical significant differences between women's knowledge and practice; also there are no statistical significant differences between women's knowledge and practice with socio-demographical variables.

Recommendation: This study findings shows the most women's source of knowledge from the internet and most of them choose a type of family planning based on

family and friends advice so the researcher recommend to activate the role of health care professional especially doctors and nurses to provide scientific knowledge and counseling to couples to choose the most appropriate method.

Funding: This research was funded by Author. Moreover, I would like to thank all the women who participated in this study and pay tribute to them for their supporting this project.

Abstract

Forest is an ecosystem that provides oxygen, wood and a place to live for a variety of flora and fauna and places where interactions between plants (flora) and animals (fauna) are present. But in its development, environmental pollution carried out by most humans that can cause environmental damage, especially forests continue to occur with a variety of motives and types. Environmental damage is getting worse. This condition has directly threatened the life of ecosystems in the forest. One example of forest destruction by human activity is exploitation of natural resources by burning the forest. Forest fires have a wider impact on society, both local, national and international communities. Areas of Indonesia that have many forests with variations in community behavior are quite prone to fires. Knowledge about natural phenomena in the form of forest fires does need to be disseminated to the community. This is important, in order to avoid the impact of the danger caused by the fire.

Keyword: *Law, Forest, Fire, Environmental Hazards.*

Introduction

Forest is an ecosystem that provides oxygen, wood and a place to live for a variety of flora and fauna and places where interactions between plants (flora) and animals (fauna) are present. Forests also have natural resource potential including teak, meranti wood, sandalwood, acacia wood, fruits, honey, rubber, spices, rattan, sago, and others.

The importance of these resources is increasing because forests are a source of livelihood for many people.[1] In Law Number 41 Year 1999 concerning Forestry, it is stated in Article 1 number 2 which reads: "Forest is a unified system in the form of an expanse of biological natural resources dominated by trees in their natural environment, which cannot be separated from one another".[2]

But in its development, environmental pollution carried out by most humans that can cause environmental damage, especially forests continue to occur with a variety of motives and types. Environmental damage is getting worse. This condition has directly threatened the life of ecosystems in the forest. One example of forest destruction by human activity is exploitation of natural resources by burning the forest.

Forest and land fires basically can occur due to two factors namely, natural factors and human activity factors either intentional or unintentional. Although there is a natural factor in the form of El Nina that hits Indonesia every year, forest and land fires caused by natural processes are very small and rare events. This is due to the type of natural forests in Indonesia that fall into the category of tropical forests or wet rain forests so that the forest floor is always wet/moist. Conversely, 99% of forest fires are caused by human activity, both intentionally and unintentionally. Only 1% of them occur naturally.[3]

Knowledge about natural phenomena in the form of forest fires does need to be disseminated to the community. This is important, in order to avoid the impact of the danger caused by the fire. Even though

forest fires are often called pure natural disasters, lately there has been a lot of human intervention in them. Thus, the discussion of the forest fire event widened by involving the phenomenon of social behavior. Forest fires have a wider impact on society, both local, national and international communities. Areas of Indonesia that have many forests with variations in community behavior are quite vulnerable.

Literature Review

Environmental Legal Theory Review

Definition of the Environment: The environment is a unity of space with all objects, power, conditions, and living things, including humans and their behavior, which affect nature itself, the survival of life, and the welfare of humans and other living things.[4]

Definition of Forest: According to forestry expert Dengler the definition of forest is a number of trees that grow on a large enough field so that temperature, humidity, light, wind, and so on no longer determine the environment, but are influenced by vegetation or new trees as long as they grow in a wide enough place and the growth is quite dense (horizontal and vertical).

According to Spurr the forest is considered as an alliance between plants and animals in a biotic association. This association together with its environment forms an ecological system where organisms and the environment influence each other in a complex energy cycle. The understanding of forests for scientists varies greatly according to scientific specifications. For example silvikur experts will provide a different understanding of the forest with forest management experts or ecologists.

Meanwhile, according to Law No. 41 of 1999 concerning forestry, forestry is a management system that has to do with forests, forest areas, and forest products that is held in an integrated manner.[5] Forest is an ecosystem unit in the form of a stretch of land containing biological natural resources which is dominated by trees in their natural environment, which cannot be separated from one another.[5] Forest area is a certain area designated and/or determined by the Government to be maintained as a permanent forest.[5]

Method

The method used through literature review, from several journals which later the author uses as a basis, comparison, and complement to conduct a review in the field of Living Environment Law.

Result and Discussion

Ways to Prevent and Handle Forest Fires: Carter (2008) explains that in disaster management activities, pre-disaster aspects must be taken seriously. He divided into three activities namely (1) preventive, (2) mitigation, (3) preparedness. Maximizing all of these stages will determine success in preventing disasters.[6]

1. **Preventive aspects:** Preventive is an effort made so that disasters do not occur. Preventive activities that can be carried out are as follows:
    1. Dissemination to the public, companies and all relevant parties that have the potential for forest fires.
    2. Education and Counseling. Practically education and counseling is carried out by the leading elements of the task force institutions namely Babinsa, Village Officials, Agricultural Extension Officers, and SKPD.
    3. Publication/Opinion through mass media. In addition to socialization and other actions, the task force by cooperating with various related parties continued to make publicity efforts about the dangers of the act of burning the forest either in the form of writing in print or in the mass media.
4. Technological innovation. Technological innovation, is specialized in the creation of certain technologies to support forest fire prevention efforts. This is based on the consideration that what is faced when forest fires are land conditions, weather, fire and human behavior.
2. **Mitigation Aspects:** Mitigation is an effort to minimize the impact of disasters. Some mitigation actions taken are:
    1. Data collection and recording. This is intended to determine the distribution and potential risk of disasters, so that efforts can be made to minimize the impact that occurs.
    2. Routine Patrol. Routine patrol activities are actions carried out by the task force on locations that are allegedly having the potential for forest fires. This patrol is carried out jointly, both from the task force and the community.
3. **Preparedness:** Preparedness is a quick step that

must be taken to respond to a disaster. Some important things to do are:

1. Establish the Governor's Decree regarding the determination of the Task Force.
2. Conducting efforts to synchronize the task force's work program with other institutions in the task force's unit.
3. Establishment of Forest Fire Management Command Posts. The number of posts is adjusted to the existing area.
4. Construction of bore wells as a source of water for fire fighting.
5. Complementary infrastructure facilities to overcome forest fires.

Law Enforcement Arrangements in the Prevention and Handling of Forest Fires in Terms of Law Number 32 Year 2009 Regarding Environmental Protection and Management in Indonesia

Enforcement of environmental law is closely related to the ability of the apparatus and the community's compliance with applicable regulations. The following are some of the means of environmental law enforcement:[7]

a. Administrative Law Enforcement Facilities. The UUPPLH contains four types of administrative legal sanctions as stated in Article 76 paragraph (2), namely, administrative sanctions consisting of: Written reprimand, Government coercion, Freezing of environmental permits, and Revocation of environmental permits.

b. Means of Civil Law Enforcement. Civil law instruments can be used in the event of an environmental dispute arising from allegations of pollution and/or environmental damage. Enforcement of environmental law through civil law can be pursued through two channels, namely:

Court Track: Settlement of disputes through the courts is regulated in Article 87 to Article 92 UUPPLH-2009, namely to demand compensation and environmental restoration. There are several principles that must be considered by the panel of judges in examining the resolution of environmental disputes through the courts as formulated in Article 87 of the UUPPLH as follows: that causes harm to others or the environment is obliged to pay compensation and/or carry out certain actions. (2) Every person who carries out the transfer, alteration of the nature and form of business, and/or activities of a business entity that violates the law does not relinquish legal responsibilities and/or obligations of the business entity. (3) The court may determine forced payment of money on any late day for the implementation of court decisions. (4) The amount of forced money is decided based on statutory regulations.[8]

Out-of-court Paths: In Law No. 32 of 2009 concerning Environmental Protection and Management of the settlement of environmental disputes outside the court regulated in Article 85 states:[9]

1. Settlement of environmental disputes outside the court is carried out to reach agreement on

(a) The form and amount of compensation,

(b) Recovery actions due to pollution/damage,

(c) Specific actions to guarantee that pollution/or destruction will not recur, and/or

(d) Actions to prevent negative impacts on the environment.

2. Settlement of disputes outside the court does not apply to environmental crimes as regulated in this Law.

3. In the settlement of environmental disputes outside the court, the services of mediators and/or arbitrators can be used to help resolve environmental disputes.

Criminal Law Enforcement Facilities: In Law Number 32 of 2009 concerning Environmental Protection and Management, environmental criminal provisions are regulated in Article 94 through Article 120. While for forest fires the criminal provisions are in Article 108 which states: Every person who burns land as referred to in Article 69 paragraph (1) letter h, shall be sentenced to a maximum imprisonment of 3 (three) years and a maximum of 10 (ten) years and a fine of no less than Rp.3,000,000,000.00 (three billion rupiah) and a maximum of Rp.10,000 .000,000.00 (ten billion rupiah).[9]

Conclusion

There are three activities to prevent and handle forest fires according to Carter (2008):

1. Preventive is an effort made so that disasters do not occur.

2. Mitigation of efforts to minimize the impact of disasters.
3. Preparedness/preparedness is a quick step that must be taken to respond to a disaster.

Means of environmental law enforcement in terms of Law No. 32 of 2009 concerning Environmental Protection and Management, namely:

1. Means of Administrative Law Enforcement, administrative law sanctions as stated in Article 76 paragraph (2).
2. Means of Civil Law Enforcement:
   - **(a) Court Track:** Settlement of disputes through court is regulated in Article 87 through Article 92.
   - **(b) Track Outside the Court:** Settlement of environmental disputes outside the court is regulated in Article 85.
3. Means of Criminal Law Enforcement, the provisions of environmental crime are regulated in Article 94 to Article 120.

In the effort to prevent and deal with forest fires, active participation in control policies implemented by the government, plantation companies and the community is needed. Prevention efforts aim to reduce the impact of forest fires because these efforts are relatively easier and cheaper than having to overcome the impacts after a fire has occurred. Therefore, it needs a growing awareness from all groups who have a concern for the preservation of forests and the environment to understand that the issue of forest fires and other environmental damage has reached an alarming level.

Study on Effectiveness of Staff Welfare Program Regarding Occupational Stress During COVID 19 Pandemic among Nursing Officers

Franny Joel Emmanuel[1], Yugmi Vala[2], Tapan Dodia[3]

[1]Nursing Tutor; M.Sc. Nursing, Child Health Nursing, Manikaka Topawala Institute of Nursing–CHARUSAT; Changa; Ta. Petlad, Dist.–Anand; Gujarat-38842, India, [2]Post-Graduate Diploma in nursing Administration, Symbiosis School for Open and Distance Learning, Pune, India, [3]MBBS, FCCCM, ISCCM, Intensivist, Ruby Hall Clinic, Pune

Abstract

Background: No wonder who you are and what you are, make your soul strong enough to fight against Stress, move ahead with joy, and let us make stress to be alone. Nursing Care for an individual no matter whether an individual is health or unhealthy, no matter from which age group S/He belongs to, however stress perception is highly subjective[1]. Work related stress amongst nursing fraternity can be generated by copious reasons. These reasons are dangerous for nurses especially during the current scenario of "COVID 19 Pandemic",this stress has been concern throughout the globe.[2]

Objectives: Researchers have set the objectives of computing the effectiveness of staff welfare program regarding Occupational stress during "COVID 19 Pandemic" among nurses.

Methodology: Researchers have used quasi experimental research design. 60 Nursing staff from a ICU of a reputed hospital of Pune city were recruited with Consecutive non probability technique. Expanded nursing stress scale (ENSS) has used to measure nurses occupational stress during "COVID 19 Pandemic". This tool is in the form of 5 point likert scale.

Results: Researchers have identified that pre-test and post-test's mean difference is 61.1in experimental group, where as in control group mean difference is 2.3.

Conclusion: It reciprocates that experimental group pre test post test mean difference has vast difference than control group, thus staff welfare program is effective in order to reduce the occupational stress during"COVID 19 Pandemic" among nursing fraternity .

Keywords: *Effectiveness; Staff welfare program; occupational stress; "COVID 19 Pandemic"; nurses.*

Introduction

Nursing is defined as a most kind profession full of knowledge, compassion, and skill. Nurses are the heart of the hospital, where they have to deal with copious obstacles in terms of physical, mental, spiritual challenges[3]. Majority of all profession or job has work stress may be physically, socially or even emotionally. Stress can be considered as a long lasting, dangerous and emotional impairment which can affect an individual's health. According to current scenario when globe is suffering with "Corona virus", and nurses are at high risk to get exposed while performing his/her duties, it is very hard to manage between personal and professional life during this pandemic, where majority of the people are having questions on their survivalist. It is a very much important to examine the nursing literature on stress and

Ph. No.: 9409026609
e-mail: frannyemmauel.nur@charusat.ac.in

one should make some strategies to reduce occupational stress[4].

Thus, researcher wants to detect occupational stress among ICU nurses, construct and administer Staff welfare program to reduce level of stress among nurses and so they become strong enough to keep aside stress and give quality of work towards their institute and feel free to work efficiently.[5] This staff welfare program includes 2 components': "strike balance with maintenance of workplace stress" and "Breathing exercise". During the hospital experience, the researchers had come across manynurses suffering from occupational stress and nurses are not focused from resolving or decreasing this stress. Hence researchers wants to put efforts to decrease this occupational stress. So, that the need for this study is an important aspect to be carried out at the time of this pandemic.

Objectives:

1. Assess the level of occupational stress during "COVID 19 Pandemic" among nursing officers in experimental group and control group.
2. Compute effectiveness of staff Welfare program regarding occupational stress during "COVID 19 Pandemic".

H_1: There will be a significant difference in post test occupational stress level between experimental group and control group.

Assumptions:

- Nurses of Selected hospital may have high level of stress level need to reduce their occupational stress level.
- They may develop interest during Staff Welfare Program
- Introducing of staff welfare program may reduce stress in nurses.

Methodology

Research Design: Quasi Experimental research design

Setting: One reputed Hospital of Pune City

Subject: Nursing Undergraduates

Sampling techniques: Consecutive non probability technique

Sample size: 60 sample (30 control group, 30 experimental group)

Variables: Demographic variable: Age, Gender, Years of experience, Marital status, Monthly salary, Education qualification, Number of dependency members in family, Year of experience at current hospital, perception of nurses for doctor, perception of nurses for other colleague, skip meal at duty, night Duty is…., are you getting rest/leave enough, Family Type.

Independent variable: Staff welfare Program

Dependent Variable: Occupational Stress

Inclusion Criteria:

1. Staff who are willing to Participate in the study
2. Staff who can read writes and understand English language.
3. Staff that are registered with nursing council.
4. Staff who is working in medical and surgical ICU
5. Staff who is having at least 1 year of experience of ICU.
6. Staff who works in ICU at the time of COVID 19 Pandemic but not associated with corona positive patients.

Exclusion Criteria:

1. Staff who are undergone to any alternative therapy.
2. Staff who has experience sudden loss
3. Staff who is having any other psychological or physical problems
4. Staff who is not available at the time of post tests
5. Staff who can't attend all the sessions of staff welfare program

Explanation of the tool: Tool comprise of 2 sections:

Section 1: Deals with 14 demographic variables. It is in the form of Semi structured Questioners with multiple choice answers

Section 2: Self modified "Expanded nursing stress scale (ENSS)" has used to measure nurses occupational stress. The ENSS is an expanded and updated revision of classic nursing scale developed by Gray–Toft and Anderson (1981).[6] This scale is used to assess

occupational stress in nurses. It is an expanded version of the original 34-items Nursing stress scale. ENSS contained 57 items in nine subscales. The 57 each items were arranged in 5 point Likert response scale.

Total score 285 which classified into, absolute grading is used

- 57: No Stress
- 58-133: Mild Stress
- 134-209: Moderate Stress
- 210-285: Sever stress

The researcher modified the expanded nursing stress scale to assess the level of stress among nurses.

Description of staff welfare program: In this research study researchers have created one program for reduction of occupational stress, it includes two components: "Strike balance with maintenance of workplace stress" and "Breathing exercise". Researchers have undergone with online certificate course on maintenance of workplace stress from udemy online course.

Manage Workplace Stress and Strike a Balance: In this component nurses will able to Identify & understand stressors, how to manage them with these techniques, How to determine priorities & values, Set smart & measurable goals, how to balance an individual's Personal life and work place life by setting up plethora of priorities and factoring in some downtime, various team building, motivating activities are been included in this welfare program.[7]

Breathing exercise: Sample are trained for 3 breathing exercise such as "alternative breathing", "Stimulating breathing technique", "Abdominal breathing." Each breathing exercise will long for 10 min[8]

Statistics: Descriptive statistics: Mean, SD, frequency distribution

Inferential Statistics: Unpaired t test

Result

The collected statistics were edited, tabulated, analyzed, interpreted furthermore findings were presented in the shape of tables and graphs representing in the following segments.

Segment I: Plotting data Frequency and Percentage data distribution of Population characteristics Variable

Segment II: Data Frequency and percentage distribution of occupational stress score

Segment III: Unpaired t test calculation

Segment I: Plotting Data Frequency and Percentage Data Distribution of Population Characteristics Variable

As per demographic data collection table shows that in experimental group 24 no. of nurses (80%) are in between 20-30 years of age, 5 no. of nurses (16.67%) are in between 32-40 years of age, 1 no. nurses (3.33%) is in between 42-60 years of age. In control group 25 no. of nurses (83.34%) are in between 20-30 years of age,4 no. of nurses (13.33%) are in between 31-40 years and 1 no. of nurses (3.33%) is in between 41-60 years

As per gender in control group 22 no. of nurses (70%) are female, 8 no. of nurses (30%) are male. In experimental group 24 no. of nurses (80%) are female, 6(20%) nurses are male.

In experience variable majority 13(43.34%) nurses have experience of 3-5 years, 10(33.33%) nurses have experience of 1-2 years and 7(23.33) nurses have experience of more than 5 years in control group. While in experimental group majority 13(43.34%) nurses have experience of 1-2 years, 11 nurses have experience of 3-5 years and 6 (20%) of nurses have experiences of more than 5 years.

As permarital data 20 no. (66.67%) of nurses are unmarried, 10 no. (33.34%) of nurses are married and in control group. Where in experimental group 17 (56.66%) are unmarried, 13 (43.34%) are married.

21(70%) nurses are satisfied from their salary and 9(30%) nurses are not satisfied from their salary in control group while in experimental group 22(73.34%) nurses are satisfied from their salary and 8(26.66%) nurses are dissatisfied from their salary.

Education qualification in control group 25(83.33%) nurses certified from GNM course, 5(16.67%) certified from BSC course. Education qualification in experimental group include 25(83.33%) nurses certified from GNM course, 4 nurses certified from BSC nursing course, 1(3.33%) certified from post basic BSC nursing course as per table number 4.

According to table no. 4, in control group 10(33.34%) nurses has more than 2 dependency members in family, 9(30%) nurses has none dependency member in family, 7(23.33%) nurses has 2 dependency members in family, 4(13.33%) nurses has 1 dependency member in family. Number of Dependency member in family in experimental group include 13(43.34%) nurses has none member, 12(40.00%) nurses has 2 members, 3(10.00%) nurses has more than 2 members, 2(6.66%) nurses has 1 member.

As per Year of experience in current hospital in control group 17(56.67%) nurses have 1 to 2 year experience, 11(36.66%) nurses have 3 to 5 year experience, 2(6.66%) nurses have more than 5 years experience. Year of experience in current hospital in experimental group include 20(66.67%) nurses have 1 to 2 year experience, 9(30.00%) nurses have 3 to 5 year experience and 1(3.33%) nurses have more than 5 years of experience.

Perception of nurse for doctor in control group 16(53.33%) nurses has excellent perception for doctors, 10(33.33%) nurses has Average perception for doctor, 4(13.34%) nurses has Poor perception for doctor. Perception of nurse for doctor in experimental group include 20(66.67%) nurses has excellent perception for doctor, 7(23.33%) nurses has Average perception for doctor, and 3 (10.00%) nurses has Poor perception for doctor as per data.

As per data, perception of nurse for other collages in control group 22(73.34%) nurses have Excellent perception for other collages, 8(26.66%) nurses have Average perception for other collages, 0(0%) nurses have Poor perception for other collages. Perceptions of nurse for other collages in experimental group include 24(80.00%) nurses have excellent perception for other collages, 5(16.67%) nurses have Average perception, and 1 (3.33%) nurses have Poor perception for other collages.

Skip meal at duty in control group 17(56.67%) nurses never skip meal at duty, 13(43.33%) nurses sometime skip meal at duty. In experimental group include 23(76.67%) nurses never skip meal at duty, 7(23.33%) nurses skip sometime meal at duty.

Night duty in control group 26(86.66%) nurses feel safe night duty, 4(13.34%) nurses feel reasonable safe night duty. Night duty in experimental group include 28(93.34%) nurses feel safe night duty, 2(6.66%) nurses feel reasonable safe night duty as per above data.

As per above table nurses who are getting rest enough in control group 19(63.33%) nurses getting rest some time, 6(20.00%) nurses never getting rest and 5(16.67%) nurses always getting rest. Nurses who are getting rest enough in experimental group include 18(60.00%) nurses are getting sometime rest, 8(26.66%) nurses always getting rest, 4(13.34%) nurses never getting rest.

Family type in control group 16(20.00%) nurses are belongs form extended family type 13(43.33%) nurses are belongs form joint family, 11(36.67%) nurses are belongs from Nuclear family type. Family type in experimental group include 16(53.34%) nurses are form joint family type, 9(30%) nurses are form Nuclear family type, 5(16.66%) nurses are for extended family type as per above table.

Segment II: "Data Frequency and Percentage Data Distribution of Emotional Intelligence Score"

Table 1: Data Frequency and Percentage data distribution of occupational stress score

Class Interval	Experimental Group				Control Group			
	Pre Test		Post Test		Pre Test		Post Test	
	Frequency	%	Frequency	%	Frequency	%	Frequency	%
57: No stress	0	0%	1	3.33%	0	0%	0	0%
58-133: Mild stress	5	16.67%	22	73.34%	9	30%	6	20%
134-209: Moderate stress	10	33.33%	7	23.33%	9	30%	9	30%
210-285: Severe stress	15	50%	0	0%	12	40%	15	50%

Segment III: "Effectiveness of Staff Welfare Program on Occupational Stress of ICU Staff Nurses"

Table 2: Mean, standard deviation, mean difference and unpaired 't' test value of pre-test and post-test score in experimental group

Variable		Mean	Mean difference	SD	DF	t- value	Table value	Significant
Occupational stress score	Pre-test	194.7	61.1	13	29	8.63	2.04	S*
	Post-test	133.6						

*(0.05,29)2.04

Inference: This table Depicts mean, standard deviation of pre-test and post-test in experimental group with the mean difference is 61.1, SD is 13, paired' is 8.63 value and p value, df value of pre-test and post-test stress level score.

Table 3: Mean, standard deviation, mean difference and 't' value of pre-test and post-test score in control group

Variable		Mean	Mean difference	SD	DF	t- value	Table value	Significant
Occupational stress score	Pre-test	182.93	2.3	14.82	29	-1.16	2.04	NS*
	Post-test	185.23						

*(0.05,29)2.04

Inference: This table Depicts mean, standard deviation of pre-test and post-test in experimental group with the mean difference is 2.3, SD is 14.82, paired' is -1.16 value and p value, df value of pre-test and post-test stress level score

Discussion

Pre-test stress level: Mean pre-test score = 194.7, pre-test stress level score reveals that 5 nurses (16.67%) are having mild occupational stress, 10 nurses (33.33%) are having moderate occupational stress and 15 nurses (50%) are having severe occupational stress. Post-test stress level: Mean post-test score = 133.6, where post-test score reveals that 1 nurse (3.33%) is having no occupational stress, 22 nurses (73.34%) are having mild occupational stress, 7 nurses (23.33%) are having moderate occupational stress and no one is having severe occupational stress. Where the control group Pre-test stress level: Mean pre-test score = 182.93, pre-test stress level score reveals that 9 nurses (30%) are having mild occupational stress, 9 nurses (30%) are having moderate occupational stress and 12 nurses (40%) are having severe occupational stress. Post-test stress level: Mean post-test score = 185.23, post-test stress level score reveals that 6 nurses (20%) are having mild stress, 9 nurses (30%) are having moderate stress, 15 nurses (50%) are having severe stress.

Conclusion

To the best of our comprehension, this literature review implicates the relationship between Occupational stress and nursing fraternities are higher. With specific association to all above mentioned studies we researchers have come up with the serious note of discussion.[6] These Review divulge plethora of facts, these facts are fascinating and interesting. This study review that there is a different score of occupational stress among nursing officers after the intervention of staff welfare program, Researchers believe that to boost the favorable condition of nursing staff and to reduce the occupational stress, an individual should emphasize to receive staff welfare program. This may also lead in positive social change, reducing emotional conflicts, resulting in high productivity.[9]

Recommendations: In the light of the above finding and personal experience of the investigator the following recommendations are offered: The study can be replicated on larger sample; thereby finding can be generalized for a larger sample. Nurses working in

any set up can use the staff welfare program (manage workplace and strike a balance and breathing exercises) to decrease occupational stress level. The department should also create such kind of Protocols to keep their nurses fit and fine.

Suggestions:

- A study can be replicated on a large sample which will facilitate more reliable research.
- A similar study can be conducted in different setting.

Ethical Consideration: Inform consent was obtained from the samples who have participated in research study in the consent form. Confidentiality of all sample's information is maintained properly.

Conflict of Interest: There is no any means of conflict of interest within the researchers

Funding Agency: Researchers have not received any fund from any agency.

Nomophobia: An Assessment of No Phone Phobia among Adolescents

Gaurav Kohli[1], Manu Kohli[2], Poonam Joshi[3]

[1]Gaurav Kohli, Professor, Chitkara School of Health sciences, Punjab, India, [2]Manu Kohli, Associate Professor, Chitkara School of Health Sciences, Chitkara University, Punjab, India, [3]Poonam Joshi, Assistant Professor, Guru Hargobind College of Nursing, Raikot, Punjab, India

Abstract

Nomophobia is a fear of being without mobile phone and it's like fear of losing phone, checking it for call but it's not ringing, mobile gaming and engage in social sites at maximum. This was a study to assess nomophobia among adolescents. The aim of study was to identify the mobile usage pattern and risk of developing nomophobia among the college students. The selected Setting was college of Education Halwara, Ludhiana, Punjab. A non-experimental/exploratory research design was utilized and 80 Elementary teacher training students were selected through consecutive sampling technique. A self – reporting checklist was utilized to assess the mobile usage pattern and rating scale assessed the risk of developing nomophobia. Analysis was done using SPSS 16.0 version. Descriptive and inferential statistics were used to analyze the data. The findings indicated that the maximum 55 (68.25%) of students follows the normal mobile usage pattern similarly the maximum 67 (83.75%) of participants were at the lower risk of developing nomophobia. There was moderate uphill (positive) relationship between the mobile usage pattern and risk of developing nomophobia.it is concluded that informative material and sensitizing sessions can help the students to cope up with this addiction.

Keywords: *Nomophobia, mobile, mobile addiction, smart phone, adolescents.*

Introduction

In the era of technology, our affections are flowing more toward gadgets than humans. Similarly, youngster's love for mobile has increased to the maximum, which is making them weaker in certain spheres of life. The word nomophobia designed for mental health problem arises from mobile usage, which is an existence of self without phone or fear of losing phone. Nomophobia also known as no-mobile phobia, which may come in situation like no network area, not recharged, battery discharged, misplaced or any other. [1]The new age mobile phone has replaced various things (diary, computer, calculator, music player, camera, video game, mode of entertainment, concerns, conversations and group involvements) of our lives, which are also predisposing causes of this irrational apprehension of being without phone.[2]

The reckless use of mobiles is unfolding the barriers to social and parental control. It's a free zone to share the views, ideas and imaginations with peer groups. Secondly, it's a major status symbol among youngsters in this era. Due to this boundary free approach, the dependency is taking toll on physical, mental, social and financial health of youngsters. Modern mobile phones are recognized as new epidemic disease of the century and the students are main affected chunk of it. It is quoted as a best measure to use in study in terms of material accessibility but more than serving the purpose it exposes our young population to its addiction. New platform of mobile phones like android can help the students in many domains of the study as comes with educational apps but it also pushing the students toward mental dependence toward mobile phones.[3]

According to data regulatory authority of India there are about 1.18 billion mobile users in India and the age group of 19-24 years reveals the high degree of penetration in usage. They show significant inclination for their own mobile phones. 2 out of 3 mobile users are unmarried or singles.[4] A study revealed that the

excessive use of mobile phone among teenagers results in restless, fatigue and insomnia. Findings of the study highlighted the percentile of mobile utilization in various life routines as 58% Indian users utilize it to maximum during air travel, 69% in cinema halls, 21% on religious place, 79% on weddings ceremonies, 25% in shopping and last 80% Indian use it on dining table. According to cross-sectional study, adolescents are mainly linked to the factors (depression, social separation, drug/alcohol use and academic failure) associated with intense mobile phone usage. The total number of 1328 samples with age limit of 31-20 years were selected in the study. The result shows that the factors like mobile phone possession is contributing to 96.5% (one phone 80.5% and >1 phone 15.9%), carry to educational institution is 54.8%, whereas 46.1% keep it on during the class even, extreme mobile dependence was calculated to 39.1% (26.1% among females and 13% males).[5]

This investigation was conducted to assess mobile usage pattern and risk of developing nomophobia; to find out the correlation between mobile usage pattern and risk of developing nomophobia; to assess the relation between mobile usage pattern and risk of developing nomophobia with demographic variables. This original paper contributed to explore the most susceptible population to Nomophobia as they are the one who carried India to 2ndrank among most gaming nations. This is a sign to explore this component of addiction prevailing with increased screen time. Researchers went through the facts available as well as carried out the investigation for same. This will help the research community to guide their investigations toward this important and less explored component of adolescents' mental health.

Materials and Method

A quantitative approach and an exploratory research design were adopted to identify the mobile phone usage and risk of developing nomophobia among students. The demographic variables of the study were age (in years), gender, father and mother education, Family monthly income, type of family and academic year, Research variables were mobile usage pattern and risk of developing nomophobia. The main study was conducted in Shri Guru Ram Dass College of Education, Halwara and sample of 80 students were selected with consecutive sampling technique. All the students were possessing smart phones and there was no exception. The tool consists of three parts i.e. sample characteristics; self-structured checklist to assess mobile usage pattern and self-structured rating scale to assess the risk of developing nomophobia. The criterion measure of tools was categorized as Mobile usage pattern checklist - Normal usage pattern and abnormal usage pattern, whereas rating scale to identify the risk of developing nomophobia was categorized as No risk, Lower risk and High risk. The tool was validated by 15 experts as well as calculated reliability of tool was 0.91 for checklist and 0.89 for rating scale. An approval was extended by the ethical committee of G.H.G College of Nursing. A written consent was taken from each participant after explaining theaim of study.An assurance was extended by the researchers about their responses will be confidential and utilized for research purpose. Researchers explained the rights to participants i.e. they can withdraw and refuse the answer as well as intervention wouldn't pose them to any physical, mental and social threat. Responses were recorded in one sitting and an average time taken by each student to mark their responses was 35-40 mins. Responses were analyzed with the help of descriptive and inferential statistics. The problem faced by the researcher to carry on this study was difficulty to get permissions as students were engaged in their coursework.

Results

Analysis and interpretations were carried out according to the laid down objectives of the study. The data was demographically distributed according to age (in years), gender, father's and mother's education, Residence place, Family monthly income, type of family and academic year. There were maximum 37 (46.25%) students in the age group of 18-19 years followed by 30 (37.5%) of students fall in 20 to 21 years of age, whereas minimum 13(16.25%) students were of >21 years. More than half 55 (68.75%) students were females whereas minimum 25 (31.25%) students were males. The maximum 39 (48.75%) students' fathers were educated between 6th – 10th followed by 19(23.75%) students' fathers were educated up to primary followed by 10 (12.5%) students' fathers were educated between 10+1-10+2 followed by 8 (10%)students' fathers were illiterate whereas minimum 4 (5%) students' fathers were educated up to graduation and above. The maximum 30 (37.5%) students' mothers were educated between 6th -10th followed by 22(27.50%) students' mothers were educated up to primary followed by 17 (21.27%) of students' mothers were illiterate followed by 8 (10%) students' mothers were educated between

10+1-10+2 whereas minimum 3 (3.33%) of students' mothers were educated up to graduation and above. The total 80 (100%) students were residing at home and no one was living in hostel. There were 35 (43.75%) students had ≤5000 monthly family income followed by 34 (42.5%) students had 5001-10000 monthly family income followed by 8 (10%) students had 10001-15000 monthly family income whereas 3 (3.33%) of students had ≥15001 monthly family income. Nearly half 49 (61.25%) of students belong to nuclear family followed by 30 (37.5 %) students from joint family whereas minimum 1 (1.25%) students belong to extended family. The maximum 46 (57.5%) students were studying in second year whereas 34 (42.5%) students in first year of elementary teacher training course. Figure 1 reveals that the 55 (68.25%) students follows the normal mobile usage pattern whereas minimum 25 (31.25%) students were in the category of abnormal mobile usage pattern.

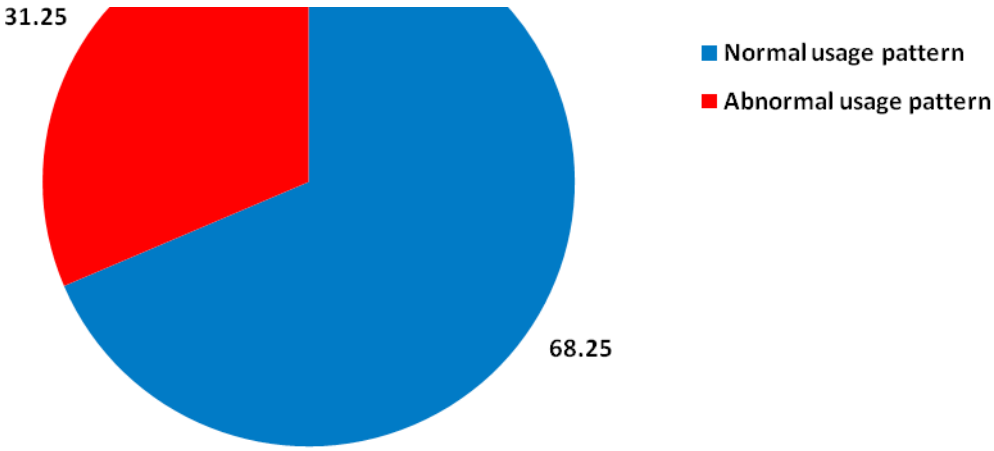

Fig 1: Percentage distribution of mobile usage pattern

Figure 2 depicts that maximum 67 (83.75%) students at the lower risk of developing nomophobia followed by 10 (12.5%) students at higher risk, whereas 03 (3.75%) students at no risk of developing nomophobia.

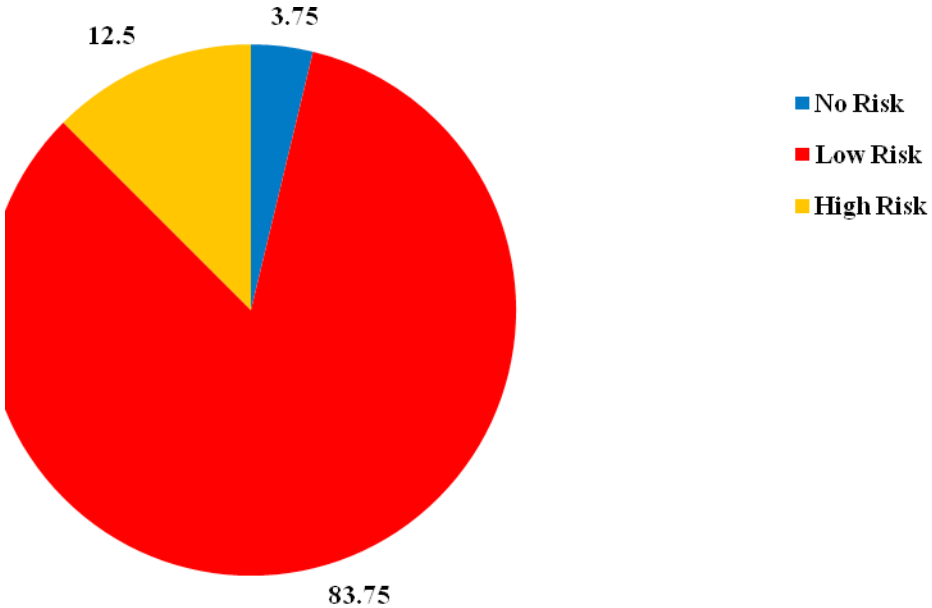

Fig 2: Percentage of risks of developing nomophobia

Table 1 depicts that the mean scores was 51.41 of students at risk of developing nomophobia, whereas the mean score was 9.16 for the mobile usage pattern of students. The calculated r value between mobile usage pattern and risk of developing nomophobia was 0.506. Hence it was concluded that there was a moderate uphill

(positive) relationship between the mobile usage pattern and risk of developing nomophobia among students.

Table 1: Correlation between mobile usage pattern and risk of developing nomophobia among students (N=80)

Correlation	N	Mean±SD	r
Mobile Usage Pattern	80	9.16±2.65	0.506
Risk of developing nomophobia	80	51.41±14.16	

Table 2 reveals the relationship between mobile usage and demographic variables. The calculated F and t values of age (in years), gender, father and mother education, Family monthly income, type of family and academic year found no significantat $p<0.05$, which means there was not significant relationship between the variables.

Table 2: Relationship between mobile usage pattern with demographic data (N=80)

Sr.No.	Demographic data	F value	P value
1	Age	0.27	0.760
2	Gender	0.19	0.421
3	Father's education	0.06	0.992
4	Mother's education	0.64	0.635
5	Family income	0.74	0.528
6	Type of family	0.70	0.496
7	Academic year	0.80	0.372

F – F value, t –t value, $p<0.05$

Table 3: Relationship between risk of developing nomophobia with demographic data (N=80)

Sr.No.	Demographic data	F value	P value
1	Age	0.866	0.424
2	Gender	5.881*	0.001
3	Father's education	0.956	0.436
4	Mother's education	0.742	0.566
5	Family income	2.110	0.105
6	Type of family	5.220	0.190
7	Academic year	2.242	0.138

F – F value, t –t value, * significant at $p<0.05$

Table 3 depicts the relationship between risk of developing nomophobia with demographic variables. It reveals that the calculated F values betweenage (in years), father and mother education, Family monthly income, type of family and academic year found no significant relationship with risk of developing nomophobia. The calculated t value between gender and risk of developing nomophobia had shown significant relations.

Discussion

The findings of study were supported by Salloju V, Ranjith B (2017)[6], the cross-sectional study was conducted to assess the severity of mobile dependency among 171 pharmacy students. The target age group was 17-25 years. Findings show that only 24.37 % of pharmacy students had risk of developing nomophobia. George S, Saif N, Joseph B (2017)[7] supports the findings of study, topic was to find the utilization of mobile among medical students in Kerala, which shows that only 35% of medical students are frequent mobile users, whereas 65% were normal mobile users. Similarly finding were reported by Kaur A, Sharma P (2015)[8]an investigation was conducted to find out the threat of producing nomophobia among students of nursing. The findings suggested that there was moderate correlation of mobile use andthreat of producing nomophobia. Mertkan D Gezgin, OzlemCakir(2016)[9] conducted an investigation to find out theprevalence of nomophobia in pre-service teachers of Trakya university and results concluded that age has relationship with the mobile usage pattern in preschool teachers. Datta S, Nelson V, Simon S (2016)[10] who conducted a study to assess the mobile use and problems reported by the students of medical education. Findings concluded that father's education has no association with mobile usage pattern in medical students. Prasad M, Patthi B, Singla A, Gupta R, Saha S, Kumar J, et al. (2017)[11]who conducted a Cross-sectional investigation of mobile usethreat of growing nomophobia Among Students of dental. The association of father's education was found not significant with risk of developing nomophobia. Sanjay Dixit, Harish Shukla, A.K Bhagwat, Arpita Bindal, Abhilasha Goyal, Alia K Zaidi, et al.(2010)[12] who conducted an investigation to find out mobile addiction in the students of medical college in India. Results showed no association of risk of developing nomophobia with academic sessions. The limitations of this research study was few studies available in the field of mobile usage pattern. Secondly the sample size limited and not containing responses from the students of other professions.

Conclusion

In this study one third (31.25%) of the total students had abnormal mobile usage pattern, which can also be referred as frequent users. The maximum number of students was not at the risk of developing nomophobia. There was a moderate uphill (positive) relationship between the mobile usage pattern and risk of developing nomophobia among students. The calculated F and t values of age (in years), gender, father and mother education, Family monthly income, type of family and academic year found no significantat $p<0.05$, which means there was not significant relationship between the variables. Age (in years), gender, father and mother education, Family monthly income, type of family and academic year had no notified relationship with risk of developing nomophobia, whereas the calculated t-value between gender and risk of developing nomophobia had shown significant relations.

Production of Bioemulsifiers from Bacteria Grown on Hydrocarbons

Ghassan M. Ahmed

Assistant Lecture, Biotechnology Department/Institute of Genetic Engineering and Biotechnology for Graduate Studies/University of Baghdad

Abstract

This work aimed to identify biosurfactant-producing bacterial strains isolated from hydrocarbon-contaminated sites and to evaluate their biosurfactant properties. The drop-collapse method and minimal agar added with a layer of diesel as carbon source were used for screening, positive strains were able to grow in a liquid medium, and surface tension and emulsification index were determined in cell-free supernatant and cell suspension. 250 bacterial isolate were tested, and 16 were positive for the drop-collapse and hydrocarbon-layer agar method. Most of the strains were *Pseudomonas*, except for three strains (*Acinetobacter, Bacillus, and Rhodococcus*). Surface tension was similar in cell-free and cell suspension measurements, with values in the range of 58 to 26 (mN/m), and all formed stable emulsions with engine oil (77-92% E_{24}). Considering the variety of molecular structures among microbial biosurfactants, they have different chemical properties that can be exploited commercially, for applications as diverse as bioremediation or degradable detergents.

Keywords: *Biosurfactants, emulsifiers, soil flora, hydrocarbon contamination.*

Introduction

One of the main causes of global contamination is the release of contaminants to the environment, including petroleum and petroleum-derived products [(1)], which also exert a risk for human and animal health since many of these contaminants have demonstrated to be toxic and carcinogenic [(2)]. Microorganisms has proven to be effective to remove the effects soil and water contamination caused by hydrocarbon, using their metabolic abilities that can modify or use hydrocarbons as a source of carbon and energy. The compounds' chemical structure and its bioavailability (concentration, toxicity, mobility, and access) can affect the efficiency their degradation[(3)]. Many microorganisms produced Biosurfactants, to metabolize water-immiscible substrates, allowing its adsorption, emulsification, or dispersion [(4)]. Aerobic microorganisms, using as carbon sources, hydrocarbons, animal or vegetal oils, or a mixture of them mainly synthesizes microbial biosurfactants[(5, 6)]. Biosurfactants can be remain attached to the cell wall (intracellularly) and/or could be released to the media [(7, 8)]. A wide range of variation in biosurfactants physical and biological properties are allowed by the main difference in the hydrophilic head chemical nature [(9)].

The term biosurfactant and bioemulsifier are considered interchangeable, but although all bioemulsifiers are considered biosurfactants, not all the biosurfactants produce stable emulsions. Biosurfactants reduce surface tension between two liquids, while bioemulsifiers induce dispersion of undissolved material throughout the liquid, by formation and stabilization of droplets of the dispersed phase [(10, 6)]. Biosurfactants produced by Microorganisms are classified by its chemical composition and its microbial origin [(10)]. Glycolipids or lipopeptides (Low molecular weight biosurfactants) can diminish surface tension but does not form stable emulsions [(3)].

The biosurfactant-producing microbial strains is an interesting research area, due tothe wide variety of uses

Institute of Genetic Engineering and Biotechnology for Graduate Studies/University of Baghdad
e-mail: ghassan.m.ahmed@ige.uobaghdad.edu.iq

and the diversity of those molecules[11]. Several method were used for isolation and screening of interesting bacterial strains; the easiestcommon method is the drop-collapse test [12], which has been described that the used carbon source to grow the microorganisms, is important on the identification of biosurfactants producing strains[5]. This work is an attempt to identify biosurfactant and/or bioemulsifier producing bacteria from soil bacterial isolates obtained from sites contaminated by hydrocarbon.

Methods

Bacterial Strains: Bacterial strains were isolated from soil contaminated obtained by selective enrichment[25]. Soil samples were taken and screened for hydrocarbon-degrading bacteria by inoculation into mineral salt agar (Na_2HPO_4 6g, KH_2PO_4 3g, NaCl 0.5g, NH_4Cl .1 g, $MgSO_4 \cdot 7H_2O$ 0.24g, and $CaCl_2$ 0.01g, Bacto-Agar 15 g, distilled water 1 l) without carbon source added to the plates, and were incubated at 25°C in a chamber saturated with gasoline vapors from 5-7 days. Colonies with different morphology were selected and inoculated into Tryptic Soy Agar (TSA) to obtain pure cultures, and periodical transfer into TSA to maintain strains[13].

Growth Conditions: Pure cultures were grown on broth added with glucose (2% w/v) olive oil, paraffin or sucrose (1% w/v), and incubated at 120 rpm for five days, according to Bodour and Miller [12]. After incubation, biosurfactant production was tested. Cells were recovered by centrifugation (12,000 x g, 5 min) and suspended in 1 ml of minimal saltbroth..

Biosurfactant production evaluation and Surface Tension Determination: The initial identification of biosurfactant-producing bacteria were done by drop-collapse method [14]. The tests were carried by triplicate, using culture supernatant and cell suspensions. Biosurfactant production was monitored in mineral salt agar plates added with a layer of a combustible material, according to the method proposed by Kiyohara *et al.*[15]. Plates were inoculated aseptically transferring a bacterial colony with sterile toothpicks were incubated at 28°C for 7 days.

In the drop-collapse test, Positive bacterial strains were also evaluated for surface tension and stable emulsion formation. Strains were grown in minimal saltbroth added with sucrose (1% w/v for *Acinetobacter*, *Bacillus*, *Rhodococcus*) or glucose (2% w/v for *Pseudomonas*) and incubated for five days at 120 rpm. For measurements of surface tension, five ml of broth supernatant tube that was submerged in water bath at 28°C. Surface tension was calculated by measuring the height reached by the liquid when freely ascended through a capillary tube[16]. The surface tension was calculated according to the formula (2):

$$\gamma = \frac{rh\delta g}{2}$$

γ = Surface tension (mN/m);

r = capillary radius (0.05 cm);

δ = Density (g/mL);

g = gravity (980 cm/s^2);

h = height of the liquid column (cm).

Emulsification Index Determination: Two ml of supernatant or cell suspension and 3 ml of a selected hydrocarbon were mixed and vortexed in a test tube for 2 min and then maintained at 25°C. The height of the emulsions layer were measured after 24 h to calculate the emulsification index[3] according to the following equation used to determine the emulsification index (E_{24}):

$$E_{24} = \left(\frac{height\ of\ emulsion\ layer}{height\ of\ total\ solution}\right) \times 100$$

Results

Bacterial Screening: Bacterial isolate were obtained from two different soils contaminated with hydrocarbons (diesel and used engineoil[17]. 250 bacterial isolates were selected for the test of biosurfactants production based on their growth on minimal saltagar plates without a carbon source and incubated in a gasoline-saturated atmosphere.. Of all isolates, 82 were obtained from a site contaminated with used engine oil and 168 from a site contaminated with diesel. According to the initial characterization (colonial morphology, Gram stain, and biochemical tests), bacterial isolates belonged to the genera *Pseudomonas*, *Rhodococcus*, *Bacillus*, *Micrococcus*, *Staphylococcus*, *Acinetobacter*, and *Serratia*. All these genera were reported to be present in hydrocarbon-contaminated sites, and hydrocarbon degraders[18,1].

Some microorganisms produce biosurfactants in water-insoluble substrates, such as vegetable or mineral oils, while other microorganisms can produce these

metabolites in presence of carbohydrates as carbon sources[5]. All 250 bacterial isolates were grown in mineral salt supplemented with glucose, sucrose or olive oil, and the supernatant was used to select for biosurfactant-producing bacteria by the drop-collapse test. Sixteen isolates were positive and of those, 11 strains were growing in glucose, six in olive oil, and only three in sucrose; of those, three strains produced biosurfactants in olive oil as well as in glucose as substrates (Table 1).

Table 1: Production of Biosurfactant and identification of isolates grown in glucose, sucrose and olive oil as the carbon source

Isolate	Source	Genera	Gram stain	Glucose	Sucrose	Olive oil

S4d1	Engine oil	Pseudomonas	N	+	-	-
S4M2	Diesel	Pseudomonas	N	+	-	-

The substrates used had been reported to promote biosurfactant production[14,19 and 20]. Although the biodegradation capacity of the 250 isolates has not been tested by the reduction of hydrocarbons in pure culture, many are likely to degrade hydrocarbons since they were isolated in mineral salt agar plates, incubated in a hydrocarbon-saturated atmosphere as carbon source. However, only a small proportion were biosurfactant producers, which support the concept of the bacterial community, that will help other microorganisms to degrade the wide variety of hydrocarbons found at the site[21,4].

The drop-collapse test was considered positive when within one minute, the drop expanded on the oily surface of the microplate lid. Besides the 16 positive isolates, another 21 strains (18 in olive oil, one in maize starch, one in sucrose, and one in paraffin) showed a partial collapsed drop after one minute, suggesting that those microorganisms produced only a small amount of biosurfactant, or it remained intracellular [14].

The majority of the positive strains were identified as *Pseudomonas* spp., which are one of the most reported biosurfactant producer, and rhamnolipid had been reported that the most known biosurfactant that they produce[22,23]. Other *Pseudomonas* related microorganisms, such as *Burkholderia plantarii*[24] and *Ps. chlororaphis*[25] also reported as biosurfactants producer.

The 16 isolates described in Table (1)were inoculated in amineral salt agar plate covered with a layer of a combustible material, a clear zone around the colonies was observed in the glucose-free plates after 24 h of incubation. Biosurfactantsare liberated to the surroundings and emulsification occurs as the main mechanism to introduce water-insoluble substrates to the cell interior [18].

Surface tension measurement showed that to give a positive drop collapse test, a surface tension lower than 45 mN/m was necessary. The surface tension of Mineral salt broth was 69.97 mN/m. No differences were observed in the surface tension of cell-free supernatants and cell suspensions for all bacterial strains tested ($p>0.05$, data are shown), opposing results obtained by Batista *et al.*[11]. The lower surface tension values, both with or without cells, was reached by *Pseudomonas* strains (26.7 mN/m) and were closely followed by the *Bacillus* strain (33.32 mN/m) (Table 2).

Even though lipopeptides produced by *Bacillus* are known as one of the most powerful microbial biosurfactants [9], *Pseudomonas* rhamnolipids are also effective, and both of them are extracellular [29]. The important point is, if a surfactant that reduces the surface tension of water can form stable emulsions [11]. The term emulsifier is often used in an application-oriented manner to describe the combination of all the surface-active compounds that constitute the bioemulsifier secreted by the cell to facilitate the assimilation of an insoluble substrate [6]. As described in Table 2, most of the strains that had lower surface tension values were also the ones that formed the largest and more stable emulsions. In addition, there was no significant difference between the emulsions formed by the released biosurfactant or the cell suspension ($p>0.05$). For all water-insoluble compounds tested, emulsions were more stable in the hydro carbonated portion of the oil-water mixture. When a supernatant without cells was used, emulsification index (after 24 hours) ranged from 0 to 99.9% for diesel, from 0.0 to 99.9% for kerosene, and from 76.2 to 92.8% for engine oil (Table 2).With high statistical differences between strains within each compound ($F=15.55$ for diesel, $F=99.9.60$ for kerosene and $F=2.35$ for engine oil respectively; $p<0.01$). For decane, the emulsion index was in the range of 0-10% and there were no differences among strains ($p>0.05$).

The emulsification index can vary with bacterial growth phase[13]. The highest emulsification index values of diesel, kerosene, and engine oil were detected for *Pseudomonas* strains. Monteiro *et al*. [22] reported an emulsification index of 70% after 30 days of incubation, demonstrating that emulsions produced by *P. aeruginosa* rhamnolipids are stable, and can be used in the control of environmental contamination. Only *Bacillus* and *Acinetobacter* formed stable emulsions with decane. Emulsions formed by *Acinetobacter* were small, but optically clear, probably due to vesicles rich in phosphatidylethanolamine that are formed, as observed by Desai & Banat [10], and the emulsion formed by *Rhodococcus* cells incorporated air in the emulsion, giving a column height higher than the controls.

Conclusion

Hydrocarbon contaminated sites can be considered as enrichment environments for the selection of hydrocarbon degrading and/or biosurfactant producing microbial strains. Production of biosurfactants and bioemulsifiers by soil microorganisms provides them with an advantage in contaminated sited, since they can use water-insoluble carbon sources for growth.

Prevalence of Head Lice *(Pediculus humanus capitis)* among Primary School Children in Baghdad Suburbs

Hadeel T. Al-Barrak

Lecturer Ph.D, College of Medicine, Ibn Sina University, Baghdad, Iraq

Abstract

A cross-sectional school-based study was performed with the objectives to determine the prevalence of head lice infestation among primary schools in Baghdad suburbs (Abu Ghraib, Al-Yousifiya, Al-Radwaniyah, Al-Al-Taji, and Al-Hussainiya). The study included examination of 920 male and female students in several elementary schools' class first to sixth (age 6-15 year). These schools include urban, rural, and economically and culturally diverse regions for the period from February to June 2018. The results of the current study showed that the total injury rate was 9%, and the Radwaniyah region recorded the highest infection rate of 13.2 and the Al-Al-Taji rejoin region recorded the lowest (6.1%). The female infection rate was greater than that of males and reached 12.3 and 5.6 respectively. The results indicated a significant relationship between the spread of head lice and the educational status of parents, sharing of the head comb, and infection with dandruff.

Keywords: *Pediculus humanus capitis, head lice, epidemiology.*

Introduction

Lice or head lice (*Pediculus humanus*) infestation is a public health problem in many developing countries where the WHO primary health care program is incompetent and random. Lice are parasitic insects that do not have wings, that live in the scalp and hair, and that they feed on small amounts of blood., And lead to skin irritation. In Iraq, external parasites, including head lice, remained neglected, according to the Center for Communicable Disease Control, in its annual reports (1986-1991), the presence of a total infection rate for head lice amounted to (0.047%) for the all population of the country. Although contamination of body lice has been almost eliminated in the world, but head lice can be seen all over the world and in Iraq, it can be seen in abundance especially in poor places with high population density and lack of personal hygiene instructions. It is easy to spread, especially among children in school, direct contact with the injured, and Share tools, brushes, towels, blankets, and clothes [(1)]. Female head lice lay around 3000 eggs, and lice transmit many diseases, such as a disease Epidemic typhus, which causes Rickettsia bacteria (*Candidatus* riesia pediculicola) that supply the lice with B-vitamins, absent in the human blood [(2,3)], and recurrent fever while feeding on human blood and causing a high body temperature [(4)]. Several studies were conducted in Iraq, including AL kubiassy [(5)] in Baghdad and Kadir *et al* [(6)] in the city of Kirkuk and a study conducted by Jabber [(7)] in the city of Amara. Despite the use of insecticides in treating head lice insects, the misuse of these pesticides and their overuse led to the occurrence of insect resistance to them and thus increases the prevalence of that insect [(8)]. The objectives of the recent study are to determine the prevalence of head lice infestation among primary schools in Baghdad suburbs

Materials and Method

This cross-sectional descriptive study was conducted in primary school children urban and rural in Baghdad suburb s (Abu-Ghraib, Tagi, Al-Yousifiya, Al-Radwaniyah and Al-Hussainiya regions from February

to June 2018. The study was conducted on 30 randomly selected primary schools to test the pupils from first to sixth grade. In general, 920 pupils residing in urban, and rural were selected in the 6-15 years age group studied individually and privately under a flashlight for all stages of the head lice life cycle such as lice/eggs (Nits), nymphs or adult lice. In this process, a handled magnifying lens was used to accurately display it using gloves and for the purpose of dispersing hair, thin wooden sticks were used to examine the presence of lice stages. The infestation was indicated when there was the adult, nymph or nits (eggs), The hair of each child examined for at least 2-3 minutes depending on hair longevity. Examined students were grouped according to their gender (sex) and age.

Statistical Analysis: Data analysis was analyzed using SPSS software, version 24. P- value ≤ 0.05 regarded statistical significance.

Results and Discussion

The rate of head lice infestation in primary schools in the outskirts of Baghdad was 9% with an average infestation by Nits 3%, Nymphs 4.6% adults 8.7%, and the infestation by more than one stage was 4.3% of the infected pupils (Table 1).

Table 1: The parasites stages on the infected head of pupils in the elementary schools of the suburbs of Baghdad

Growth stage	Number examined	Infected	Infection rate %
Nits (Egg)	920	28	3.0 %
Nymph	920	42	4.6 %
Adult	920	80	8.7%
More than one stage	920	40	4.3 %
Chi squ are test P-value 0.001***			

*** Very high significant (P < 0.001)

The results indicated that there are statistical differences for head lice infestation between the suburban areas of Baghdad, where the region of Al-Radwaniyah topped the infection rate by 13.4% and the lowest infection was recorded 6.1 % of the Al-Taji region (Table 2).

Table 2: Prevalence of head lice infestation in relation to Baghdad suburbs

Provence	Number examined	Infected	Infection rate %
Abu-Ghraib	177	17	9.6 %
Al-Hussainiya	171	13	7.6 %
Radwania	201	27	13.4%
Tagi	297	18	6.1 %
Yousfia	74	8	10.8 %
Total	920	83	9 %
Chi squ are test P-value 0.049			

In Iraq, several epidemiological studies of head-lice were performed and a wide range of infection rates was observed. In Baghdad the infestation rate ranged from 2.9% [9] to 48.9% [10]. In city of Kirkuk 20% [11], in city of Samarra 15.29% [12]. And in Mosul 33.2%[13]. In addition, infestation in rural areas outpaced urban areas, by 10.1% and 7.5% respectively, and that may be due to better hygiene in urban area, higher socio-economic levels, and better family education. These results were consistent with what found by Nejati [15], who reported a 6.58% and 12.44% prevalence of pediculosis in urban and rural areas in Iran

The results also proved that the female infection was more than the male infection, as it recorded 12.3 % and 5.6 %, respectively (Table 3). This significant difference can be attributed to the behavior patterns between boys and girls, which have affected prevalence rate such as girls 'clothes. Moreover, girls generally have longer hair compared to boys and long hair that requires better combing. Moreover, fit female hair as a place for breeding head lice, covering female hair with scarf etc.

Table 3: Prevalence of head lice infestation in relation to Gender

Gender	Number examined	Infected	Infection rate %
Male	449	25	5.6 %
Female	471	58	12.3 %
Total	920	83	9 %
Chi squ are test P-value 0.001			

All Iraqi studies indicated a high rate of infection among females compared to that of males, and it is believed that the difference in the infection between the sexes with head lice does not have a physiological basis, but rather depends on the difference in hairstyle, as long, wavy hair is a predominant characteristic of older girls and the few number of cuts hair in females helps to maintain and permanence of the injury [16]. This phenomenon can be explained by the fact that girls have longer hair, which facilitates the transmission of lice from head to head, that they are more social, and often touch the hair of other girls. Additionally, in long hair, nits remain attached to hair growth accordingly, these are signs of previous infection, which were successfully treated, and remained for months, while short boys' hair was cut, and led to removing head lice.

With regard to the relationship of head lice infestation with the age group (Table 4), it was observed that the highest rates of infection were a group of age 6–7 to 12-13 years % in both sexes (P > 0.05). This result is consistent with what Al-Aboody (16) found that head lice infestation abounds within the ages from 7 to more than 11 year, and Salehi [17] who found that there were no statistical differences between the ages of primary school students for grades 1 through 6 in Isfahan, Iran.

Table 4: Prevalence of head lice by age group of primary schools in Baghdad suburbs

Age group	Number examined	Infected	Infection rate %
6-7 yr	339	35	10.3 %
8-9 yr	256	21	8.2 %
10-11 yr	214	18	8.4 %
12-13 yr	91	8	9.9 %
14–15 yr	20	1	5 %
Chi squ are test P-value 0.843			

In Present study, the frequency of washing of hair, the number of family members, sharing bed and towels, and the length of the hair did not differ significantly between affected and uninfected children. Whereas, parent education, the habits of sharing combs, and the presence of dandruff had a significant effect on the prevalence of head mice in pupils of elementary schools (Table 5). The percent of infected pupils whose parents were uneducated was 19.1% compared to 4.5 for pupils whose parents were educated (P-value < 0.001). Likewise, the percentage of infection increased with the presence of dandruff, where the infection rate was recorded 52 and 48%, respectively. Sharing combs recorded 97.6% of the haired combs. These results are consistent with Degirli [18], Nejati [19].

Table 5: Prevalence of head lice in relation to frequency of bathing, sharing towel, sharing beds, sharing combs, hair length, and dandruff infection of primary schools in Baghdad suburbs

Character	Number examined	Infected	Infection rate %	P-value
Parent Education				
Educated	637	29	4.5%	0.001***
Not educated	283	54	19.1%	
Frequency of bathing				
1 a week	789	71	9.0%	0.882
2 a week	115	10	8.7 %	
3 a week	16	2	12.5 %	
Sharing Towel				
Sharing	868	78	9.0	0.878
No Sharing	52	5	9.6	
Sharing Beds				
Sharing	54	29	9.0	0.992
No Sharing	599	321	9.0	
Sharing Comb				
Sharing	882	81	9.2	0.041*
No Sharing	38	2	5.3	
Hair Length				
Short	255	16	6.3	0.137
Medium	456	43	9.4	
Long	209	24	11.5	
Dandruff				
Infected	140	43	23.5	0.001***
Not infected	737	40	5.4	

*,*** Probability value < 0.05, < 0.001 respectively

Conclusion

The results obtained from the current study showed a greater prevalence among children aged 6-12 years with greater of the female gender, housing in rural areas, children who shared head combs jointly with the rest of the family, children with dandruff in the scalp and children whose parents are not educated. Our suggestion is that social and economic levels and health conditions should be improved for the successful treatment of lice infestation, by raising parents' awareness through educational programs.

Estimating the Concentration of Lead and Cadmium for Some Areas of Najaf Governorate

Hakeem J. I.

Assistance Prof., Department of Environment, Faculty of Science, University of Kufa, Najaf, Iraq

Abstract

The study showed that lead element is higher than the normal limits due to the high level of gases. Which makes the concentrations of lead vehicles in the fuel used high. Cadmium is within the normal level because the sources of this element in the study areas are limited.

Keywords: *Heavy metals, pollution, concertation, health, raw materials.*

Introduction

Heavy elements, or what is known as heavy metals, are defined as those elements that are more than five times the density of water, and they have negative effects on the environment when they are used excessively, as they affect human, animal and plant health[1].

Lead is one of the most dangerous and widespread pollutants as a result of the significant development achieved in the chemical and mining industries and the growing uses of this mineral in various technologies[2]. The importance of any source of exposure to lead differs according to the geographical location, climate, ground chemistry and industrial activities, as well as the exposure intensity that the individual faces with different age, gender, profession, food, and culture. The population of developing countries is higher because their lead protection rules are less stringent than in developed countries[3].

Cadmium is one of the toxic heavy metals that play an important role in environmental pollution and constitutes a threat to human and animal health alike[4,5], as it is found in nature in a pure form linked with other raw materials[6] and is excreted to the environment from industrial waste and from agricultural fertilizers[7].

Materials and Method

Sample collection

Soil samples were taken from the most traffic-crowded areas in the province of Najaf

1. Intersection of the airport
2. The intersection of the twentieth revolution
3. The intersection of Al-Sahedrin
4. Al-Zahra'a intersection
5. Al-Wafa University intersection
6. Al Mukhtar Tunnel
7. The intersection of the northern transportation garage
8. The intersection of the southern transport garage
9. Najaf - Karbala checkpoint
10. Najaf Control - Abu Sukher

The chemicals used:

1. Hydrochloric acid
2. Nitric acid

Method of measuring concentrations

After drying and grinding the sample and sifting it, we do the following

1. Take (0.5) grams from the sample and put it in a conical flask
2. Digest the sample by adding a 3: 1 ratio of hydrochloric acid to nitric

3. Evaporate the sample by placing the beaker on a constant heat source until all the liquid has evaporated
4. We add nitric acid with 2% dilution.
5. Filter the sample and supplement the filtrate to 100 ml with distilled water
6. The sample is measured using atomic absorption technology

Results and Discussion

Table 1 shows the concentration of lead in soil samples for some areas of Najaf Governorate. Table 2 shows the concentration of cadmium in soil samples for some areas of Najaf Governorate.

Table 1 Concentrations of lead

Region	Lead (ppm)
Al Mukhtar Tunnel	0.142
Najaf-Karbala checkpoint	0.171
The intersection of Al-Sahedrin	0.191
Twentieth Revolution Zone	0.174
The control of Abu Sakhir	0.12
Airport junction	0.161
The intersection of Wafa-Jahma	0.12
Southern garage	0.141
North garage	0.191
Al-Zahra'a intersection	0.135

Table 2 Concentrations of cadmium

Region	Cadmium (ppm)
Al Mukhtar Tunnel	0.0182
Najaf-Karbala checkpoint	0.015
The intersection of Al-Sahedrin	0.0189
Twentieth Revolution Zone	0.0121
The control of Abu Sakhir	0.011
Airport junction	0.01
The intersection of Wafa-Jahma	0.009
Southern garage	0.015
North garage	0.0058
Al-Zahra'a intersection	0.017

The study showed that the levels of the lead element are higher than the normal limits due to the high level of gases emitted from cars, as these areas are very congested, especially at peak time, and the lack of control over the specifications of fuel used in automobile engines, which makes the concentrations of lead vehicles in the fuel used high. Cadmium is within the normal level because the sources of this element in the study areas are limited.

Conclusions

Lead element are higher than the normal limits due to the high level of gases emitted from cars. Cadmium is within the normal level because the sources of this element are limited.

Ethical Clearance: This study was approved by the Ethics Committee, University of Kufa. The study protocol was thoroughly explained for using samples This investigation was done according to the principals of the Declaration of Helsinki.

Abstract

The purpose of this study is to investigate the association between socio-demographic characteristics and perceived health among Syrian refugees in Jordan.

Method: A cross-sectional quantitative descriptive design was adopted, where a sample of 151 Syrian refugees living inside and outside camps in Amman,Jordan was surveyed for physical, psychological, social and environmental perceived health using a 12-item questionnaire.

Results: Each domain's score was computed out of 60. The mean perceived physical health was 27.6±11.5; perceived psychological health 27.1±10.1; perceived social health 32.6±10.3; and perceived environmental health 30±9.1. Predictors of perceived physical health included age group $F_{(2)} = 3.12$, $p = .012$, marital status $F_{(3)} = 4.71$, $p = .004$, and income level $F_{(2)} = 1.75$, $p = .047$. Predictors of perceived psychological health included income level $F_{(2)} = 2.79$, $p = .005$, place of living $t = 3.32$, $p = .007$, and marital status $F_{(3)} = 4.09$, $p = .034$. Predictors of perceived social health included gender $t = 2.04$, $p = .026$, age group $F_{(2)} = 3.64$, $p = .000$, living place $t = -3.61$, $p = .031$, and household size $r = .61$, $p = .048$. And the only predictor of perceived environmental health included was place of living $t = 5.64$, $p = .000$.

Conclusion: Living inside refugee camp, large household, poverty, older age, and being divorced or widow are associated with lower perceived health. Modifying some factors may help improve perceived health among Syrian refugees in Jordan and beyond.

Introduction

As a result of political turmoil, destruction, and armed conflict, millions of Syrians have become refugees, faced with the reality of fleeing their previous lives, their homes, and sometimes, even members of their families. They have headed to other regions in Syria, or other countries in search of safety and protection [1]. Since the fighting in Syria began in 2011, more than 470, 000 people have been killed, 1 million injured, and several millions forced to flee their homes for fear of persecution and seek asylum elsewhere[1]. Syrian refugeesfled to neighboring nations such as Lebanon,

Jordan, and Turkey in order to stay safe and salvage their lives and their family's lives[2].

Jordan historically hosted several waves of refugees from neighboring countries, such as Palestine and Iraq [3]. Today, Jordan alone hosts over 680 thousand registered Syrian refugees, but this only represents a fraction of the total number of Syrian refugees in country, which is estimated to be 1.4 million, or 20% of Jordan's population [2]. The vast majority of Syrian refugee communities in Jordan (approximately 80%) are located in non-camp settings, specifically in cities close to the Northern border between Jordan and Syria, including Mafraq and Irbid, and in the capital, Amman[4]. Over 85% of Syrian refugee population live under poverty line [4].

The aforementioned circumstances make the daily life of Syrian refugees filled with hardships and stressors on the physical and social levels. Syrian refugees often live with limited means to provide shelter and food to their children and families, representing basic necessities of survival[5]. There is no question that Syrian refugees residing in Jordan face grave and often insurmountable financial barriers towards accessing basic health services, which leads to poor health[3]. Therefore, this paper investigates the socio-demographic predictors of Syrian refugees' perceived physical, psychological, social and environmental health.

Materials and Method

Design: A cross-sectional quantitative descriptive design was utilized to identify association between socio-demographic characteristics (such as gender, age group, place of living, family size, marital status, educational level, employment status and income level) as independent variables, and perceived physical, psychological, social and environmental health as dependent variables.

Settings: Sample was recruited from Syrian refugee communities inside Zaatari refugee camp, and in non-camp settings in greater Amman and Zarqaa.

Sample and Population: A sample of 151 registered Syrian refugees aged 18 years and above, willing to participate were included in this study. Those with terminal illnesses or severe disabilities were excluded.

Data collection Procedures: Data collection started after acquiring ethical approval from the Institutional Review Board (IRB) Committee of the School of Nursing, The University of Jordan. Potential participants were approached in their communities between September and November 2019, merit of the study and its benefits were explained, informed consent was signed, and then the Arabic questionnaire was completed.

Instrument: The data was collected using a two-part questionnaire:

1. Socio-demographic data that include gender, age group, place of living, family size, marital status, educational level, employment status and income level.
2. A 12-item, Arabic, self-reported, perceived health questionnaire with four domains; perceived physical, psychological, social and environmental health. This questionnaire was developed by the authors in light of reviewing several international instruments. Face validity was confirmed by three experts.

Pilot Study: A pilot study on 22 subjects prior to the main study. Result showed satisfactory reliability with a Cronbach's alpha of .82.

Findings:

Sample Characteristics: As presented in table (1), the sample consisted of 151 adult Syrian refugees whose ages ranged between 18 and 69 years, with a mean of 31.3 years (SD = 10 years). Age was recoded into three age groups for statistical purposes, as shown in the table. Majority (73.5%) were males, and married (54.3%), 31.8% were single, and those a few reported being widowed (7.3%) or divorced (6.6%). Ninety-one participants (60.3%) resided outside camp in Amman or Zarqaa', and 60 participants (39.7%) resided in Al-Azraq refugee camp. In terms of educational level, 38 participants (25.2%) reported receiving education lower than middle school, 20 participants (13.2%) had middle school education, 70 participants (46.4%) had high school education, and only 23 participants (15.2%) had some college or university degree. Those who reported a monthly family income below absolute poverty line (at about JD200 per month per household) were only 7 (7.3%), those who reported a family monthly income between absolute poverty line and poverty line (at about JD400 per month per household) were 36 (37.5%), and those who reported a family monthly income above poverty line were 53 (55.2%) (DOS, 2019). It is important to report that out of the 151 participants,

55 decided not to answer the income question, so the numbers in the table add up to 96 participants.

Table 1. Sample Characteristics (N = 151)

Characteristic	Count (%)
Gender Male	111 (73.5)
Female	40 (26.5)
Age Group 18-29 years	73 (48.3)
30-39 years	54 (35.8)
40 years or older	24 (15.9)
Marital Status Single	48 (31.8)
Married	82 (54.3)
Widowed	11 (7.3)
Divorced	10 (6.6)
Living Place Inside Camp	60 (39.7)
Outside Camp	91 (60.3)
Educational Level Below Middle School	38 (25.2)
Middle School	20 (13.2)
High School	70 (46.4)
College or Higher	23 (15.2)
Employment Status Unemployed	75 (49.7)
Employed	76 (50.3)
Family Monthly Income Level* Below JD199	7 (7.3)
JD200-299	36 (37.5)
JD300 or Higher	53 (55.2)

*55 participants (36.4%) chose not to answer this question

Perceived Health Scores

A 12-item, Arabic language questionnaire was used to test the perceived health score for each of the four domains; physical, psychological, social and environmental. Items of the questionnaire were Liker-scale type ranging from extremely poor to extremely satisfying. Each domain's score was computed out of 60.

The score for perceived physical health ranged between 4.5 and 56.9, with a mean of 27.6±11.5 out of 60; perceived psychological health scores ranged between 4 and 52.7 with a mean of 27.1±10.1 out of 60; perceived social health scores ranged between 6.8 and 60, with a mean of 32.6±10.3 out of 60; and perceived environmental health scores ranged between 5.8 and 58.8, with a mean of 30±9.1 out of 60.

Socio-demographic Predictors: The scores of each of the four domains of perceived health was tested for its association with socio-demographic characteristics. These characteristics included gender, age group, marital status, employment status, household size, educational level, income status, as well as living place (inside vs. outside camp). This association was tested using a series of independent-sample t tests, one-way ANOVA tests, and Pearson's r correlation tests according to each variable type. A number of socio-demographic characteristics were found to be significantly associated with each of the four domains' scores, and are therefore considered predictors.

Socio-demographic predictors of perceived physical health included age group, where participants aged 18-29 scored 31.3, those aged 30-39 scored 27.8, and those aged 40 or older scored only 24.4 ($F_{(2)}$=3.12, p=.012); marital status, where single participants scored 28.8, married scored 26.9, divorced scored 22.9, and widow/er scored only 22($F_{(3)}$=4.71, p=.004); and income level, where participants whose families receive a monthly income below JD199 scored only 25.8, those between JD200-299 scored 27, and those above JD300 scored 30.1($F_{(2)}$=1.75, p=.047).

Socio-demographic predictors of perceived psychological health also included monthly income level,where participants whose families receive a monthly income below JD199 scored only 28, those between JD200-299 scored 29.2, and those above JD300 scored 31.4 ($F_{(2)}$=2.79, p=.005); place of living, where refugees inside camps scored 26.9, and those outside camps scored 29.6(t=3.32, p=.007); and marital status, where single participants scored 27.8, married scored 27.1, divorced scored 23.5, and widow/er scored only 22.9 ($F_{(3)}$=4.09, p=.034).

Socio-demographic predictors of perceived social health included gender, where males scored 32.6, and females scored 29.9 (t=2.04, p=.026); age group, where participants aged 18-29 scored 33, those aged 30-39 scored 29.7, and those aged 40 or older scored only 26.2($F_{(2)}$=3.64, p=.000); living place, where refugees living inside camps scored 32.6, and those living outside camps scored 27.3(t=-3.61, p=.031), and household size, where a statistically-significant correlation was found between number of household members and perceived social health score (Pearson's r=.61, p=.048).

Finally, the only socio-demographic predictor of perceived environmental health was place of living, where refugees living inside camps scored 29.6, and those living outside camps scored 33.7(t=5.64, p=.000). All other socio-demographic characteristics were not significantly associated with the score of environmental health domain.

Discussion

Numerous research found a strong association between health and socio-demographic factors in several populations, namely among refugees [3]. Regarding living inside refugee camps, the findings of this study came in line with the results of a 2017 study by Alduraidi & Waters, where Palestinian refugees inside refugee camps fared worse in terms of both physical and environmental health, but fared better in terms of social relationships[5]. The explanation of these findings may be the strong connections between refugee families inside the camp, and the shared concerns, hopes and stressors between these families.

Regarding the association between poverty and inferior physical health, a 2015 study by Hamdan-Mansour and colleagues suggested that poverty predicted worse health and life satisfaction among Jordanian patients[6]. This association was also evident in a 2020 study by Alduraidi and colleagues, where Syrian refugees with lower financial resources demonstrated lower resilience than their younger counterparts[7].

In terms of the association between age and perceived physical and psychological health, the findings of this study came in line with those of a 2017 study by Hamdan-Mansour and colleagues and a 2020 study by Khatib and colleagues, as well as a 2020 study by Alduraidi and colleagues[8-9-7]. It is worth mentioning that another 2017 study by Hamdan-Mansour and colleagues, and a 2019 study by Saleh and colleagues have revealed that the older the person, the more likely he/she is to express inferior physical health problems both subjectively and objectively[10-11].

Furthermore, relatively-high numbers of divorced and widow individuals, and relatively large family size are characteristics of refugee communities as revealed in a 2018 study by Alduraidi & Waters, where these socio-demographic characteristics were found to be significantly associated with distress, sadness, and poor perceived psychological health[3].

Conclusion

The findings of this study provide an evidence that some modifiable socio-demographic characteristics are associated with inferior perceived health scores among Syrian refugees in Jordan. Poverty and large household size were associated with inferior perceived physical, psychological and social health. It is, therefore, recommended that policy makers should target resolving the problem of limited financial resources and large family size among Syrian refugees in Jordan.

Living inside refugee camp was associated with inferior perceived psychological and environmental health on one hand. On the other hand, perceived social health inside the camp was superior. Policy makers should, therefore, establish psychological/mental health services, and work on improving physical environmental conditions inside the camp. Meanwhile, policy makers should implement solutions for promoting social support networks among refugees outside the camp. Finally, older refugees, divorced and widow individuals expressed low scores in several domains. Thus, policy makers are invited to implement programs to help promote health in these special demographics.

Abstract

Psychosocial burden as a result of the risk of decreasing income and the possibility of being laid off from work is a problem that must be faced by workers during the COVID-19 pandemic. The study was aimed at analyzing predictors of psychosocial burden among workers during the co-19 pandemic period. A total of 6,053 worker respondents were involved in this study. The psychosocial burden was reviewed based on the worries level. There were 4 independent variables involved in the analysis, including age, gender, marital, and education. A multivariate test was performed using binary logistic regression. The results found that the workers in the ≤ 19 age group were 1.900 times more likely than the≥ 50 age group to experience a psychosocial burden. The workers in the 40-49 age group were 1.523 times more likely than the ≥50 age group. Male workers were 0.693 times more likely than female workers to experience a psychosocial burden. The higher education workers were 0.563 times more likely than workers with secondary education. It could be concluded that the 3 variables were proven as predictors of the psychosocial burden among workers during the COVID-19 pandemic period in Indonesia, namely age, gender, and education.

Keywords: *Mental health, workers, psychosocial burden, health behavior, COVID-19.*

Introduction

The pandemic of COVID-19 is not going to end very soon shortly. There are some arguments to support the statement. The most recent number of COVID-19 cases in the world indicate that the number of new cases was increasing in the past 7 days from July 9th, 2020 to July 16th, 2020. The detailed information can be accessed in the www.worldometers.info/coronavirus/. Based on the website, it was also informed that the mortality rate of this disease was around 7% at the global level.

e-mail: hario.megatsari@fkm.unair.ac.id

The number of COVID-19 cases in Indonesia has not decreased trend. It can be seen on the official website of the government, namely www.covid19.go.id. Based on the website accessed on July 15th, 2020, the number of COVID-19 cases in Indonesia spread all over the province and district/city. And there is no indication the outbreak will end soon[1].

The Indonesia government has taken several strategies to stop the chain of transmission of COVID-19. Some of the strategies are issuing Minister of Health Regulation No. 9 of 2020 concerning Large-Scale Social Limitation Guidelines in the context of accelerating the handling of COVID-19. The regulation regulates the restrictions that must be obeyed by the society. These restrictions include schools being closed, public transportation stopped, work from home, and so on. The main idea of the regulation is to lessen the movement of the community[2,3].

The impact of these regulations and restrictions have an impact on all sectors of social life, namely religious aspects, economic aspects, aspects of education, and aspects of social psychology. This can be seen from the many facts reported by the mass media about the impact of these restrictions, including the existence of a group of people who still have to work even though the regulation has been enforced in their territory[4]. The longer the Large Scale Social Restrictions, the more violations committed by the community[5].

The limitation of community mobility during COVID-19 can potentially trigger anxiety in the form of depression and stress on society[6,7]. Anxiety is also reported because of the health beliefs that originate from the large amount of hoax information scattered on social media, which worsens the atmosphere[8–10]. The situation of the mass psychology getting worse due to the theory of conspiracy echoed by celebrities and influencers[11,12], including conspiracy theories believed by the president of the USA, Donald Trump, as a form of celebrities and influencers resistance to the existence of the power of his government[13].

Public anxiety can lead to new public health problems. WHO defines health as a good condition in 3 dimensions of human life, namely the physical, social, and mental dimensions[14]. Anxiety is included in an unhealthy condition in WHO's perspective, so special attention is needed to pay close attention to the community's situation, especially in the current outbreak of COVID-19.On the other hand, the rate of unemployment during COVID-19 was increasing due to the situation of pandemic[15,16]. Based on the background description, this study is intended to analyze the predictors of psychosocial burden among workers during the COVID-19 pandemic period in Indonesia.

Materials and Method

The study was conducted by collecting data through online surveys of people who claimed to have jobs, who are domiciled throughout Indonesia. Data collection was carried out for 8 days (June 6-13, 2020). A total of 6,053 worker respondents were included in this analysis.

Psychosocial burden variables were arranged based on the worries level. The worries level was built based on the assessment of anxiety in 5 aspects of daily life, namely economic, religious, educational, employment, and social aspects. The questions in the questionnaire were arranged with five answer choices (Likert scale). Assessment of the worries level by adding up scores from 5 aspects measured, then dividing it into 2 categories of psychosocial burden, which were not worried and worried.

Four independent variables were included in the analysis. The four variables are age group, gender, marital status, education level. Age group was the respondent's acknowledgment of the last birthday that has passed. Age groups were divided into 6 categories, namely ≤ 19, 20-29, 30-39, 40-49, and ≥ 50. Gender was divided into 2 categories, namely male and female. Marital status consists of 3 categories, namely single, married, and divorced/widowed. Education level was the respondent's recognition of the level of education that has been passed. Education level was divided into 2 categories, namely secondary and below, and higher.

The variables involved in this study, both dependent and independent, were dichotomous variables. Researchers used the bivariate test at an early stage with the Chi-Square test. This initial test was to select the independent variables that will be included in the next test phase. The multivariate test at the final stage was carried out using binary logistic regression to determine the predictors of psychosocial burden among workers during the COVID-19 pandemic period in Indonesia. All stages of analysis in this study were carried out with the help of SPSS software version 22.

Results and Discussion

Table 1 is a display of descriptive statistics of the characteristics of worker respondents. It can be seen that workers who have a psychosocial burden are dominated by workers who are in the age group of 20-29 and have female gender.

Based on marital status, the married workers dominate groups that have a psychosocial burden. While based on education level, the workers who have higher education dominate both categories of the psychosocial burden.

Information about the result of the binary logistic regression of psychosocial burden among workers during the COVID-19 pandemic period in Indonesia is presented in Table 2. All selected variables are included in this final analysis.

Marital status: Widowed/Divorced	0.690	1.094	0.702	1.706
Education Level: Secondary	-	-	-	-
Education Level: Higher	***< 0.001	0.563	0.458	0.692

Note: $^{*}p < 0.05$; $^{**}p < 0.01$; $^{***}p < 0.001$.

Table 2 shows that the workers in the ≤ 19 age group were 1.900 times more likely than the ≥ 50 age group to experience a psychosocial burden (OR 1.900; 95% CI 1.026-3.519). The workers in the 20-29 age group were 2.652 times more likely than the ≥ 50 age group to experience a psychosocial burden (OR 2.652; 95% CI 1.999-3.518). The workers in the 30-39 age group were 1.992 times more likely than the ≥ 50 age group to experience a psychosocial burden (OR 1.992; 95% CI 1.607-2.470). The workers in the 40-49 age group were 1.523 times more likely than the ≥ 50 age group to experience a psychosocial burden (OR 1.523; 95% CI 1.227-1.889). Information from the results of this analysis shows that age is a predictor of psychosocial burden among workers during the COVID-19 pandemic period in Indonesia. The workers who have the oldest age have the lowest possibility to experience psychosocial burdens.

Age as a predictor of psychosocial burden is also reported in several studies in various countries[17–19]. Older age is directly proportional to more life experiences. The senior workers have a more coping mechanism in dealing with uncertain situations during the COVID-19 pandemic period[20,21].

Table 2 informs that male workers are 0.693 times more likely than female workers to experience psychosocial burden (OR 0.693; 95% CI 0.598-0.803). The results of this analysis indicate that gender is a predictor of psychosocial burden among workers during the COVID-19 pandemic period in Indonesia. The female workers have a higher chance of experiencing psychosocial burden.

Consistent information was also found in previous studies. The female group was reported to have more potential to experience mental disorders in the form of depression and anxiety compared to the male group[22]. Male workers are considered more able to cope with uncertainty pressures during the pandemic than female workers[23].

Table 2 shows that workers with higher education are 0.563 times more likely than workers with secondary education to experience psychosocial burden (OR 0.563; 95% CI 0.458-0.692). This information shows that education level is a predictor of psychosocial burden among workers during the COVID-19 pandemic in Indonesia. Higher education has a lower probability of experiencing psychosocial burden.

Better education is directly proportional to the ability of workers to respond to the COVID-19 pandemic situation. Educational factors make a person able to understand information and digest the situation better so that they are better prepared to deal with uncertain situations during the COVID-19 pandemic[24,25]. Several previous studies inform that education is often found as a positive predictor of health sector performance[26–28].

Conclusions

Based on the results of the analysis it could be concluded that 3 variables were proven to be predictors of the psychosocial burden among workers during the co-19 pandemic period in Indonesia. The four variables were age group, gender, and education level.

Acknowledgments: The author would like to thank all the Persakmi and IKA Airlangga Surabaya who have allowed the use of online survey data about this psychosocial.

Source of Funding: Self-funding

Conflict of Interest: The authors declare no conflict of interest, financial or otherwise.

Ethical Clearance: This study of the psychosocial burden of community during the COVID-19 pandemic period in Indonesia has received ethical approval from the national ethics commission (No: RK.05/KEPK/STIK/VIK/2020). The respondents' identities have all been deleted from the dataset. Respondents have provided written approval for their involvement in the study.

Abstract

The family is a collection of two or more people, with each other tied to each other emotionally, and living in the same area in an adjacent area. Family support is the attitude, actions, and acceptance of the family of its members. Anxiety is an individual's response to an unpleasant situation experienced by all living things in everyday life. The purpose of this study was to determine the relationship of family support with anxiety levels in pre-school age children in the children's care room at Syech Yusuf Hospital Gowa Regency. This research method was analytic descriptive with a cross-sectional study design. The research sample of 31 people using Purposive Sampling techniques. Place of research in the Children's Care Room Syech Yusuf Hospital Gowa Regency. The study was conducted from July to October 2019. The data collection used questionnaire sheets. Data analysis using the chi-square test. The results showed that family support of 31 respondents, the highest frequency of respondent family support was good as many as 16 respondents (51.6%) and the lowest frequency was enough as many as 15 respondents (48.4%). Data on children's anxiety level were obtained from 31 respondents, the highest frequency of respondents' anxiety level was 19 respondents (61.3%) and the lowest frequency was weight, which was 12 respondents (38.7%). Based on the results of the Chi-Square statistical tests that have been done, it was obtained that the value of X2= 14,685 with a significant level of ρ = 0,000 with α = 0.05. The conclusion of the study showed that there was a relationship between family support and anxiety levels in preschool children.

Keywords: *Family Support, child anxiety level.*

Introduction

Family support is the attitude, actions, and acceptance of the family of its members. Family members see that supportive people are always ready to provide help and assistance if needed.[1]

Family social support is a process that occurs throughout life, the nature and type of social support vary in various stages of the life cycle. However, at all stages of the life cycle, family social support makes the family able to function with a variety of intelligence and reason. As a result, this improves health and family adaptation.[1]

Family social support refers to social support that is seen by the family as something that can be accessed or held for the family (social support can or is not used, but family members view that supportive people are always ready to provide help and assistance if needed). Family social support can be in the form of internal family social support, such as support from husband or wife and support from siblings or external family social support.[1]

The family is expected to be able to function to realize the process of developing mutual love and affection between family members, between relatives, and between generations which are the basis of a harmonious family, .[2] Family relationships are a happy home. In a life characterized by compassion, all parties are required to have a responsibility, sacrifice, mutual help, honesty, mutual trust, mutual understanding, and peace in the home.[2]

Both buffering effects (social support withhold the negative effects of stress on health) and major effects (social support directly influencing health effects) were found. Indeed the buffering and main effects of social support on health and well-being may function together. More specifically, the existence of adequate social support is associated with decreased mortality, easier recovery from illness and among older people, cognitive function, physical and emotional health.[1]

The family is an important element in care, especially care for children. by because children are part of the family, the nurse must be able to recognize the family as a place to stay or remain constant in the child's life.[3]The child's stature at the hospital is a stressful experience, both for children and parents. The hospital environment itself is a cause of stress and anxiety in children. In children who are hospitalized, challenges will have to be faced such as overcoming a separation, adjusting to an unfamiliar environment, adjusting with many people to take care of it, and often having to relate and interact with sick children and experience following the painful therapy.[4]

Preschoolers experience the greatest anxiety when they first enter the hospital due to the illness conditions experienced by children. If the child experiences high anxiety during hospitalization, the child will likely experience developmental dysfunction. Children will experience disorders, such as somatic, emotional, and psychomotor disorders.[5]

Reaction to illness or self-problems experienced by preschoolers such as separation, not knowing the environment or unfamiliar environment, loss of affection, body image will react like a regression that is a loss of control, displacement, aggression (denying), withdrawing protest behavior, and more sensitive and passive such as refusing to eat and others.[6]

Nearly four million children in one year were hospitalized. The average child gets treatment for six days.[7] In addition to requiring special care compared to other patients, sick children also have special features and characteristics because children are not miniatures of adults or small adults. And the time needed to treat patients with children 20-45% more than the time to care for adults.[7]

The estimated 35 per 100 children undergo hospitalization. The Effects of Play Therapy in Reducing Anxiety in Preschool Children (2.5-5 years) who experienced Hospitalization at the Tugurejo Regional General Hospital, the data obtained in 2006 preschool children who experienced hospitalization were 122 children, in 2007 there were 642 children, in 2008 there were 977 children, in 2009 there were 929 children, in 2010 there were 223 children, in 2011 there were 181 children.[8]As many as 45.2 % of families provide strong support and 41.9% of families provide strong support and only 12.9% of families provide very strong support, both from the nuclear family and extended family.[9]

The population of children being treated in the hospital has experienced a very dramatic increase.[10] The percentage of children being treated at the hospital is now experiencing more serious and complex problems than the incidence of hospitalization in previous years. Nearly 4,000,000 children were hospitalized in one year, the average child being treated for six days.[7]

The results of the initial survey conducted in the nursery were obtained as follows: in the nursery in January to December 2017 the number of preschool children (3-6 years old) treated by 219 patients in Syech Yusuf Gowa Regional Hospital with an average child was suffering from a high level of anxiety which was around 98%.

Materials and Method

The type of research used was descriptive-analytic with a Cross-Sectional approach, data concerning independent variables or risk and dependent or effect variables, collected at the same time.[11] In this study, researchers conducted data collection on the Relationship of Family Support and Anxiety Level. The population is a group area consisting of objects and subjects which become certain quantities and characteristics expected by researchers to be studied and then drawn conclusions.[12] The population in this study were all children ages preschool children admitted to Syech Yusuf hospitals and Hospitalized in the Pediatric ward with the average number of patients preschoolers January to April

2018 at 57 preschoolers. The instrument used for data collection in this study was to use an observation sheet. The family support observation sheet, has 20 questions, and the family support measurement scale used can be measured with a Likert scale) with the highest scale 4 and the lowest scale 1. The resulting score is between 20-80 where family support is good: 61-80, adequate family support: 41-60, family support lacking: 20-40. Data processing procedures were performed through the stages of editing, coding, data entry, and cleaning, and data analysis through the analysis procedure univariate and bivariate analysis using the chi-square test.

Results

Family Characteristic of Respondents of this study described as part of research subject. Respondent (Children's family) in this study based on gender, consisted of the male was 4 respondents (12,9% and female was 27 respondents (87.1%).

Table 1: The Age Group of Respondent (Children's Family)

Age (years old)	Amount	
	Frequency	%
< 25	13	41.9
25 – 34	8	25.8
35 – 44	8	25.8
> 45	2	6.5
Total	**31**	**100**

Table 1 showed data from the 31 respondents, the highest frequency in the age group <25 years was 14 respondents(41.9%) and the lowest frequency in the age group>45 years was as much as 2 respondents (6.5%).

Table 2: The Occupation of the Respondent (Children's Family)

Pekerja and fscsddd Occupation	Amount	
	Frequency	%
Civil Servants	3	9.7
Traders/Entrepreneurs	3	9.7
Farmers	8	25.8
Private employees	2	6.5
Unemployed	15	48.4
Total	**31**	**100**

Table 2 showed data from the 31 respondents, the highest frequency of respondent's occupation was as a civil servant as many as 10 respondents (32.3%) and the lowest frequency was Private Employees as many as 3 respondents (9.7%).

Table 3: Education Level of Respondents (Children's Family)

Education Level	Amount	
	Frequency	%
Elementary school	3	9.7
Junior High School	10	32.3
Senior High School	13	41.9
University	5	16.1
Total	**31**	**100**

Table 3 showed data from the 31 respondents, the highest frequency of education of respondents was Senior High School (13 respondents (32.3%) and the lowest frequency was elementary school, which was 3 respondents (9.7%).Number of Respondent Children (Children's Family) in this study showed data from the 31 respondents, the highest frequency of 1-2 respondent children was 19 respondents (61.3%) and the lowest frequency was 3-4 children, which was 12 respondents (38.7%).

Table 4: Age of Respondent Observed (Children hospitalized)

Age of Children (years old)	Amount	
	Frequency	%
3	12	38.7
4	12	38.7
5	3	9.7
6	4	12.9
Total	**31**	**100**

Table 4 showed data from the 31 respondents, the highest frequency of the children was 3 years and 4 years old, each with 12 respondents (38.7%), and the lowest frequency was 5 years of age with 3 respondents (9.7%). Respondent observed (Children hospitalized) in this study based on gender, consisted of the male was 11 respondents (35.5% and female was 20 respondents (65.5%).

Hospitalized experiences of respondents (hospitalized children) data from the 31 respondents showed that the highest frequency of respondent's

hospitalized experience was 29 respondents (93.5%) never been hospitalized and the lowest frequency was ever been hospitalized as many as 2 respondents (6.5%). The care length of respondents (hospitalized children) showed data that most of the children had been hospitalizing for 1 day as much as 28 respondents (90.3%), and 3 respondents (9.7%) had been hospitalizing for 2-3 days when this study was conducted.

In this study, we found data from the 31 respondents, the highest frequency of respondent family support was in good category as many as 16 respondents (51.6%) and the lowest frequency was in enough category as many as 15 respondents (48.4%). The Anxiety Levels of Preschool children hospitalized found data from the 31 respondents, the highest frequency of respondents' anxiety level was 19 respondents (61.3%) in mild-moderate level and the lowest frequency was severe anxiety, which was 12 respondents (38.7%)

Table 5: Family Support Relationship With Anxiety Levels in Preschool Children Hospitalised in Pediatric Ward Syech Yusuf Hospital Gowa, Indonesia 2019

Family Support	Anxiety Level				Amount	
	Mild-Moderate		Severe			
	n	%	n	%	n	%
Good	15	48.8	1	3.2	16	51.6
Enough	4	12.9	11	35.5	15	48.4
Total	**19**	**61.3**	**12**	**38.7**	**31**	**100**

$X^2 = 14.685$, p-value = 0.000

From table 5 above showed data from the 31 respondents, it was found good family support that was as much as 16 respondents (51.62%) and enough family support that was as much as 15 respondents (48.4%), whose level of anxiety was 19 respondents (61.3%) in mild-moderate level and had severe anxiety level experienced by 12 respondents (38.7%).Based on the Chi-Square statistical test results that have been obtained, the results obtained a value of X^2=14.685 with a significant level of p=0.000 with α=0.05.

Discussion

This study showed the results from the analysis were p=0,000<α=0.05 so that according to the basis of the hypothesis research decision making[11] Ho was rejected and Ha was accepted. This means that there was a relationship between family support with the level of anxiety in children ages preschool.

Family support is one factor that can help children in coping with stressors. Family support can have a buffering effect that is family support holding back the negative effects of stress on health and the main effect that is family support directly influences health improvement.[1] High parental support will also increase self-esteem, coping abilities of children in dealing with various stressors faced during hospitalization. With this coping ability, the level of anxiety experienced by children when hospitalization can be minimized.

Parents are encouraged to stay with young children as long as possible so that the separation behavior is minimized. The willingness of parents to stay depends on their involvement with children at home, their work situation, and their level of comfort with the hospital, as well as the amount of support they receive from other family members and friends in meeting the needs of other family members.[13]

The factors that influence anxiety responses in sick children who are hospitalized are not only due to family support but there are other factors including the foreign environment, the presence of strangers, medical equipment, inability to do activities, pain due to medical action/injury to the body. Here family support only exerts a few percent influences.[14]

For children, illness is a difficult time, where the child must leave a familiar environment, move to a hospital that is still unfamiliar to him, in a state of illness and loneliness, and must undergo a variety of frightening treatment procedures.[15] Foreigners who are around (in the hospital) for children ages preschool considered the person who threatened her. Moreover, health workers (nurses or doctors) who always carry out medical actions that are considered painful so that children easily arise anxiety when interacting with strangers to him.

Children aged 3 to 6 years are at the stage of psychosocial development initiative vs guilt. The psychosocial development stage (Erikson) of children aged 3 to 6 years is characterized by intrusive and energetic behavior, the courage to strive, and strong imagination. The explanation of pre-school age children's fantasy toward strange or excessive environments.[16] Children aged 3 years experience the highest increase in attention span when compared to ages 4.5 and 6 years[17] so this is a compelling reason to explain why 3-year-olds experience the most moderate anxiety.

Conclusion

The family support for children was hospitalized in the pediatric ward of Syech Yusuf Hospital Gowa, Indonesia available for all children treated during this study. Nevertheless, the support received by every child varied from one another. There were 51.6% of children had a good category of family support while 48.4 children got enough category of family support from their family during hospitalization. The highest anxiety level of 31 respondents, the frequency of mild to moderate anxiety level of respondents were 19 respondents (61.3%) and the lowest frequency was severe, as many as 12 respondents (38.7%) in preschool-aged children who were hospitalized in the pediatric ward of Syech Yusuf Hospital Gowa. There was a relationship between family support with the level of anxiety in preschool children hospitalized in the pediatric ward of Syech Yusuf Hospital Gowa, Indonesia.

The Effect of Qourum Sensing genes (*lasI, rhlI*) in Some Virulence Factors of *Pseudomonas aeruginosa* Isolated from Different Clinical Sources

Hasan Falah Lahij[1], Abdulla H. Alkhater[2], Muthanna Hamid Hassan[1], Luma Amer Yassir[3]

[1]Lecturer, Biology Department-Collage of Sciences, University of Anbar, Ramadi, Iraq, [2]Scholar researcher, Al-Maarif University Collage, Department of Medical Laboratory Techniques, Iraq, [3]Prof, National Center of Hematology, Al -Mustansiryah University, Baghdad, Iraq

Abstract

Background and Objective: Quorum sensing (QS) is a chemical language of bacteria, and use of N-acyl-homoserine lactone (AHL) signals is one of the most known mechanisms by which bacteria can communicate with each other to regulate the gene expression based on bacterial density. Previous studies suggested that QS has an important role in pathogenicity of *P.aeruginosa*, so that the present study investigation the correlation of QS genes in local isolate of *P.aeruginosa* with production of virulence factors.

Materials and Method: The study included collection of 126 samples from various clinical sources and, these samples included wounds, burns, ear, cystic fibrosis and urinary tract infections (UTI). Pyocyanin and biofilm production were determined spectrophotometrically, QS genes were detected by PCR based on specific sequences for *lasI and rhlI* genes.

Results: Final diagnosis showed that 51 isolates belong to target bacteria and, the phenotypic detection of some virulence factors showed that 46 isolates (90%) showed variance in the strength of Pyocyanin production, and 44 (86%) of the isolates showed a differences in their ability to biofilm formation and, screed QS genes showed that 48 (94%) of isolates were positive for *las*I gene, while 44 (86%) of isolates have *rhlI* gene, and this study pointed that 9 isolates have one of QS genes *lasI* or *rhlI*, and also have one or more of virulence factors, as well as the results showed that 1 isolate out of 51 negative for both QS genes and weakly in production of virulence factors.

Conclusion: Most of local isolates were positive for QS genes and, QS plays an important role in the pathogenesis, not all of the virulence factors controlled by QS. The study indicated that the isolates which have both QS genes were more virulence than isolates that have single gene.

Keywords: *Pseudomonas aeruginosa, Quorum sensing, virulence factors, Biofilm, Pyocyanin.*

Introduction

Pseudomonas aeruginosa is a successful opportunistic secondary pathogen and most predominant species in community infection[(1)]. Immunosuppressed people are the individuals remain at high risk of this infection such as those with severe burns, cancer, cystic fibrosis and acquired immune deficiency syndromes (AIDS)[(2)]. The virulence factors of *P. aeruginosa* play an important role in the pathological state, the survival of the bacteria and the invasion of host tissues[(3)].

Bacteria have chemical molecule which mediated cell to cell communication system to regulate gene expression and group activates within communities[(4)].

Quorum sensing (QS) was first discovered in the marine bioluminescent bacterium *Vibrio fisheri* in the period early 1970 [5]. QS is widely spread in the bacteria, and considered as a "speaking" systems, QS plays major role in virulence factor production, and biofilm formation [6]. The communication occurs through small molecules called acyl homoserine lactones (AHL) also known as "Autoinducers" that diffuse freely across the membranes of bacteria when bacterial density increase, these molecules when reach to threshold concentration act as a cofactors of transcriptional regulators [7].

P.aeruginosa has two of QS system *las* and *rhl* system[8]. The las system consist of *lasI*, which is responsible for the synthesis of N-(3-oxododecanoyl)-L-homoserine lactone (3O-C12-HSL), and the transcriptional activator *LasR* [9], the *las*R binds to (3-oxo-C12-HSL) molecule and regulates expression of specific genes [10]. While another QS system in *P. aeruginosa* consists of the *rhlI* and *rhlR* genes [11,12]. The *rhlI* synthase responsible for produce of the AHL (N-butyryl-L-homoserine lactone (C4-HSL), and *rhlR* is the transcriptional regulator only when *rhlR* is complexed with C4-HSL does it regulate the expression of several genes (rhamnolipid,elastase cyanide,alkaline protease, and pyocyanin production [13]. Briefly *lasI* and *rhlI* genes activate of *lasR* and *rhlR* gene to activate encoding virulent genes.

The QS system contributes in increase virulent of *P. aeruginosa*. However, only a few local studies are available concerning the role of *P.aeruginosa* QS systems in various clinical infections. So that the present study try to understanding the role of QS gene in production of virulence factors (pathogenicity) in local isolates of *P.aeruginosa*.

Methodology

The study samples (126) were collected from clinical state including both sexes with different ages, who suffered from; cystic fibrosis, urinary tract infections, wounds, burns and ear infection from different teaching hospitals in Baghdad city. The study was carried out through May 2016 till May 2017.

Laboratory and Molecular Diagnosis: The samples cultured in Pseudomonas agar and Cetramide agar. Lab. diagnosis was done according to Holt *et al* [14] while the molecular diagnosis was done based on *16SrRNA* gene as a detection gene.

Detection of some Virulence Factors: Pyocyanin production determinate according to Parsons *et al* [16] and, biofilm formation method was done according to Bose *et al* [17].

DNA extraction method: The bacterial DNA extracted according to Genomic DNA mini Kit which provides by Geneaid Company.

PCR technique used for Detection of QS Genes and *16SrRNA*gene

Primers (table1) were designed by Primer3 program according to **NCBI** and supplied by the Bioneer Company as a lyophilized product of different picomol concentrations.

Table 1: Sequence of primers and their size

Gene		Sequence of forward and reverse Primer(5´- 3´)	Size (bp)	Annealing Temp.°C
16SrRNA	F	GGGGGATCTTCGGACCTCA	956	58
	R	TCCTTAGAGTGCCCACCCG		
Las I	F	GCGCGAAGAGTTCGATAAAA	537	60
	R	ATCTGGGTCTTGGCATTGAG		
Rhl I	F	CTTGGTCATGATCGAATTGCTC	626	61
	R	ACGGCTGACGACCTCACAC		

F: Forward sequences, R: Reverse sequences

Sequencing of *lasI* and *rhlI* genes: To search for the presence of mutations that may affect the QS genes, *lasI and rhlI* underwent sequencing according to Senturk (23).

Results

The collected samples were cultured in some media agar to initially diagnosis based on morphological characteristics of the colonies. Molecular detection used to confirm final diagnosis of all isolates. The result of gel electrophoresis (figure 1) for amplification PCR product showed that presence of bands in same level for all isolates. Final diagnosis of *P.aeruginosa* showed that 51 isolates belong to target bacteria.

Pyocyanin pigment estimated by measure of absorbance in ELISA reader equipment (VERSAmax microplate reader, Molecular Devices, USA) at 690nm, the results showed that 46 (90%) of isolates have ability to produce pyocyanin through 3 days of incubation but in varying degrees (figure 2). While the results of biofilm formation showed that 44 (86.2%) of isolates produce biofilm**.**

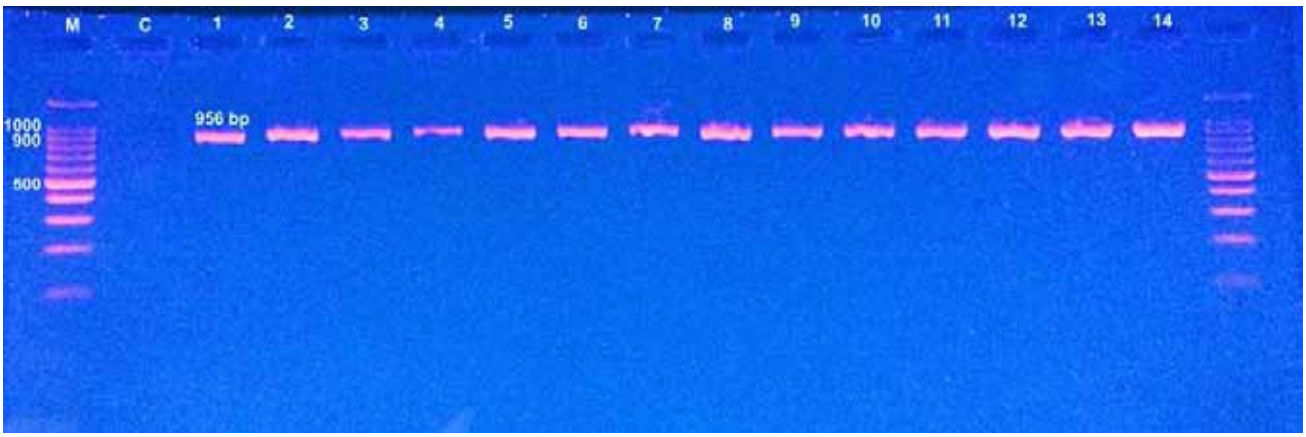

Figure 1: Agarose gel electrophoresis (1.5%agarose, 7 V/cm^2 for 90min) of *16SrRNA* gene (956bp). Lane M: represent 100bp DNA ladder, Lane C: represent negative control, Lanes 1-13: represent bands of *P.aeruginosa* gene.

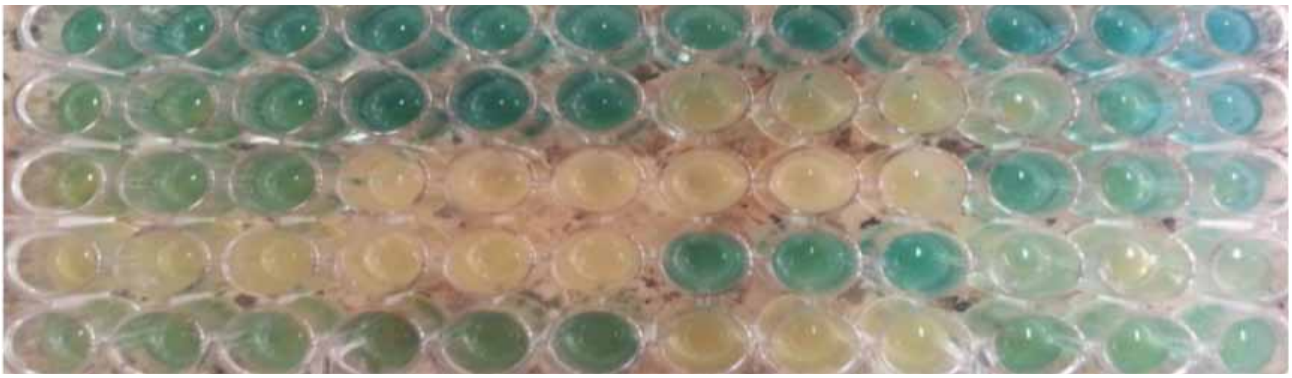

Figure 2: Produce of pyocyanin pigment by *P.aeruginosa* isolates.

Molecular detection of (QS) genes by used specific primers for *lasI and rhlI* genes showed that 48 (94.1%) of isolates were positive for this gene, where are the bands appeared within the expected size of the gene (537bp) for all positive isolates (Figure 3) .While 44 (86.2%) of isolates have *rhlI* gene (Figure 3), the results pointed that 9 isolates have one of QS genes *lasI* or *rhlI*, and also have one or more of virulence factors, and one isolates out of 51 negative for both QS genes. To determine if QS genes have mutations in some isolate, sequence analysis of the PCR products showed that no difference in sequences where the percent of matching 100% for *rhlI* gene and 99% for *lasI* gene when comparing with the information bank within the site www.ncbi.nlm.gov.

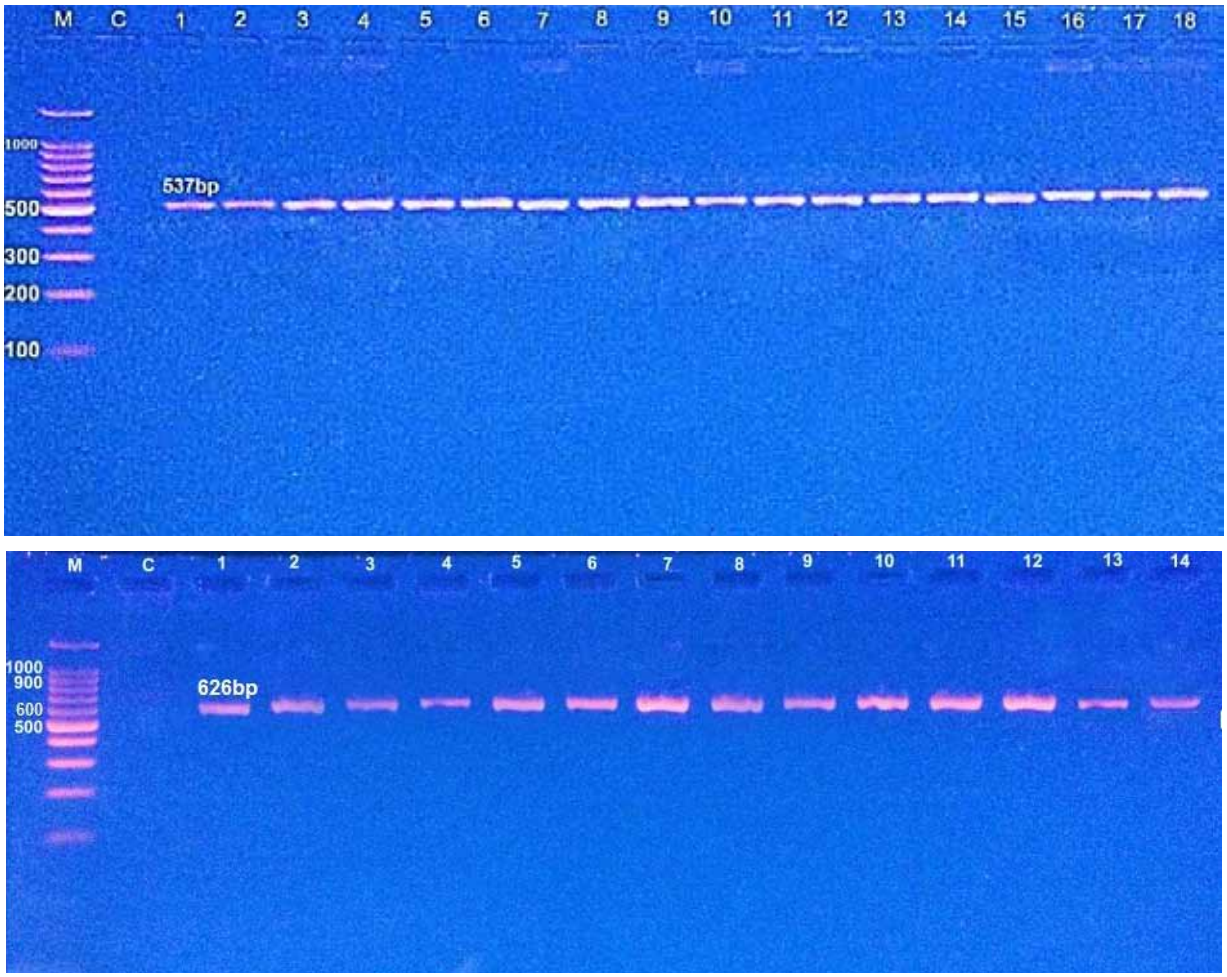

Figure 3: Agarose gel electrophoresis (1.5%agarose, 7 V/cm^2 for 90min) for (a) *rhlI* gene (626bp) and (b) *lasI* (537bp). Lane M: represent 100bp DNA ladder, Lane C: represent Negative control, Lanes 1-14, 18 represent bands of *P.aeruginosa* gene.

Discussion

In the present study examined the role of QS in production of some virulence factors of *P. aeruginosa* in various clinical infections. Final diagnosis based on molecular detection of *16SrRNA* gene which is considered one of the basic criteria in the classification because of highly constant and unable to change over time of its regions [15], showed that 51 isolates belong to target bacteria and, highest percentage of clinical isolates belong to burns followed by wounds, this may be explain that *P.aeruginosa* is one of the more bacterial species that cause burns and wounds infection in hospitals.

Virulence factors (Biofilm and Pyocyanin) were examined spectrophotometrically, result of biofilm formation indicated that most of isolate were able to biofilm formation, but in varying degrees with compare to negative control, the isolates capable to form biofilm ranged in intensity among high, medium and weak adherent. The high productivity of biofilm formation may be back to sensitivity of way to measure the few quantities formed, and considered important method in studying the early stages of biofilm formation [19], this results agree with Heydari and Eftekhar) [18]. While pyocyanin production increases over time, this explains the state of competition among bacterial cells on nutrients whereas the pigment consider is an antagonist, also our result nearly with Oleiwi [20].

Many studies and reports indicated that there is a strong correlation among QS system and biofilm formation, where the results of biofilm formation showed that (43/44) of isolates which have able to biofilm form were positive to QS genes. The *las* gene plays an

important role in maintenance of *P.aeruginosa* biofilm, where that the signaling 3-oxo-C12-HSL (synthesized by *LasI*) is necessary for the establishment of *P. aeruginosa* biofilm, whereas a *lasI* mutant forms a flat and thin biofilm, and *lasI* is expressed in a large number of cells during the initial stage of biofilm formation [22]. QS genes regulate the production of pyocyanin pigment, whereas results of pyocyanin production showed that 39/46 of isolates which are able to produce of pyocyanin were positive to *rhl*I gene.

Among of 51 isolates identified one isolate was defective in production of all virulence factors, but have QS gene*s lasI* and *rhl*I, this result may be indicated to absent of *lasR* or *rhlR* genes, because sequencing analyses revealed no mutation in *lasI* or *rhlI* gene of this isolate, or may be ways used in detect virulence factors were not sensitive to very few quantities produced by this isolate. This study pointed that 9 of isolates have one of QS genes *lasI* or *rhlI*, and also produce one or more of virulence factor. As well as the results showed that 1 isolate (P35) out of 51 negative for both QS genes and weakly in production of virulence factors these isolate from wound, this results agree with [24] who identified QS deficient in clinical isolate which lost all virulence factors tested, but still caused a wound infection, suggested that in addition to known virulence factors, there may be another factors yet uncharacterized involved in the pathogenesis of *P. aeruginosa.* Another possibility that may indicate or lead a QS deficient strain to cause infection is the presence of multiple strains of *P. aeruginosa* in the same infection site.

The present study confirm that important role of QS systems in Pathogensis of *P. aeruginosa* bacteria and also indicated that *P. aeruginosa* able to causing clinical infections in humans despite an weakness of QS system in some isolates. On the other hand these results do not contradict with theory that QS system plays a main role in *P. aeruginosa* pathogenicity, and not all virulence factor controlled by QS [21].

Conclusions

Most of local isolates of *P.aeruginosa* were positive for QS genes, also QS plays an important role in the pathogenesis of *P.aeruginosa* infection in varous, not all of the virulence factors controlled by QS system. The *lasI* gene has important role in the production of bioflim. Detection of bacteria by *16SrRNA* gene is very simple and rapid technique compare with other conventional method.

Total Matrix Metalloproteinase-2 and Prostaglandin E2 as Potential Biomarkers in Iraqi AML Patients

Hassnien S. AL- Hashemi[1], Sabah A. Hameid A. Rahman[2], Zeyad A. Shabeeb[3]

[1]Assistant Lecturer, MSc Clinical Immunology, National center of Hematology, Mustansiriyah University, Iraq, [2]Professor, PhD Clinical Physiology, College of Science, Mustansiriyah University, Iraq, [3]Assistant Professor, PhD Clinical Immunology, National center of Hematology, Mustansiriyah University, Iraq

Abstract

Acute Myeloid Leukemias (AMLs) are rare but extremely malignant neoplasms that are liable for a big amount of fatalities associated with cancer. Acute myeloid leukemia (AML) results from accumulation of abnormal myeloblasts, most commonly in the bone marrow, leading to bone marrow failure and death. The present study was carried out to evaluate MMP-2 and PG E2 in sera and of (50) AML Iraqi patients, In addition to control group involving (50) matched apparently healthy subjects. This study was done in the National center of hematology, Department of biology at AL-Mustansiyria University, Baghdad Medical City since January 2019 to June 2020. The aim of study was to determine the level of total Matrix Metalloproteinase 2 and prostaglandin E2 in patients with AML by ELISA. and study the impact of these parameters on the pathogenesis of disease, also predict the AML and how the parameters correlated with stages and severity of disease and responsiveness to therapy. Conclusion: MMP-2 decreased and elevated of PGE2 in the serum of AML patients .

Keywords: *AML, MMP-2,PGE2, ELISA, Matrix metalloproteinase, prostaglandin E2.*

Introduction

Matrix Metalloproteinase-2 (MMP-2) and Prostaglandin E2 (PG E2) Roles in AML: The Matrix Metalloproteinase (MMP) family was discovered from studies of collagen breakdown during tadpole morphogenesis[(15)]. Matrix Metalloproteinase (MMP) are now known as a family of 24 homologous Zn2 + -dependent proteinases essential for normal extracellular matrix (ECM) breakdown, growth factor secretion and cytokine activation during wound healing, tissue remodeling, embryogenesis, neovascularisation, cell migration, and immune response regulation[(33,26)].

MMP-2, also called gelatinase A, promotes the invasion and metastasis of cancer cells by destroying the collagen IV, V and X present in the ECM and basement membranes[(16)].

MMPs play an significant role in the development of hematologic malignancies. Most of the research centered on the role of MMP-2 in leukemia gelatinases. Shows the role of hematopathogenesis MMPs in hematological disorder. This explains the role of MMPs and their inhibitors in hematological malignancies including MDS, AML and chronic myeloid leukemia [(35)].Higher angiogenesis was observed in patients with acute leukemia, which vanished if complete hematological remission was achieved[(10,27,28)]. The increased vessel density found in the AML bone marrow correlated with the expression of the vascular endothelial growth factor (VEGF) [(7)]**;** Hence a role is hypothesized for other angiogenic factors such as matrix metalloproteinases. No expression of MMP-2 could be detected in normal mononuclear bone marrow cells[(19)]. Matrigel may be invaded by primary AML blasts, depending on their

MMP-2 expression[31]. MMP-2 expression may also contribute to the increased vessel density observed in AML patients' bone marrow during diagnosis by promoting in vitro cell migration[10]. Abnormal expression levels of MMP-2 were observed in AML patients and myelodysplastic syndrome (MDS)[32]. MMP-2 has a low level of expression in myeloid cells; MMP-9 is found primarily in T lymphocytes, malignant B lymphocytes and mature myeloid and monocytic cells[1].

Prostaglandin E2 also called dinoprostone belongs to the family of lipid hormone-like signaling eicosanoids with essential inflammatory and physiological functions [8].Most eicosanoid molecules are made from the enzymatic modification of arachidonic acid (AA), a polyunsaturated fatty acid esterified in mammalian cell membrane phospholipids [4]. PG E2 is produced omni presently and acts as autocrine and paracrine lipid mediators to maintain local homeostasis in the body. Both level and profile of prostaglandin (PG) production change drastically during an inflammatory response. The production of PG in uninflamed tissues is normally very low but increases immediately in acute inflammation before leukocyte recruitment and immune cell infiltration [29]. Biosynthesis of prostaglandin is blocked by non-steroidal anti-inflammatory drugs (NSAIDs), which inhibit the action of either cyclooxygenases or both. In addition to their role in homeostasis, prostanoids can modulate immune responses and contribute to tumor initiation, vascularization and chronic inflammation[30] .

The mechanisms that underlie PGE2's effects on cancer growth are, elusive. In a recent review, Zelenay et al. presented first direct evidence that PGE2 could promote tumor growth by evading immune attacks in melanoma models for murine tumor transplantation[36].

Tumor derived prostaglandin E2 (PGE2) plays a major role in suppressing the activity and survival of CTLs in patients undergoing immunotherapy for cancer. PGE2 have also been shown to suppress survival of CTLs, interferon type I production and in vitro cytotoxicity Previous evidence shows that exhausted CTLs increased the expression of certain inhibitory receptors including the PGE2 receptors EP4 and EP2 using profiling of the entire genome expression[25]. In AML blasts, PGE2 has been shown to be upregulated as opposed to mononuclear blood cells[13]. It has elevated serum levels of prostaglandin E2 in patients with acute lymphoid leukemia. Upon full remission with induction chemotherapy, the elevated plasma prostaglandin E2 levels decreased significantly[22].

Method

The study was conducted on 50 Iraqi patients with acute myeloid leukemia and 50 matched healthy looking subject. The age range of the patients within 17-80 years. This study was done in the National center of hematology, Department of biology at AL-Mustansiyria University, Baghdad Medical City since January 2019 to June 2020 . Each patient was subjected to physical examination done by specialist and illness –information related to this research were obtained.

This assay employs the quantitative sandwich enzyme immunoassay technique (ELISA) (for Total MMP-2 and PG E2 in serum, the kits was used from R & D Systems,USA.

Result and Discussion

The present study demonstrated a statistically significant decreased level of Matrix Metalloproteinase 2 in patients with AML as compared with control subjects ($p<0.01$) **Table (1) Figure (1))**the current findings were agreed with (Lin *et al.,* 2002) who show there was lower level of MMP-2 in the AML patient Also another report in Egypt[3] that mentioned there were decrease in the level of MMP-2 in AML patients.

In Iranian study[6] who showed the MMP-2 levels in AML patient were not much higher as compared to normal bone marrow (BM) donor.

An association of MMP-2/-9 expression with invasive activity of leukemic cells in acute lymphoblastic leukemia (ALL) and acute myelogenous leukemia (AML) has been recorded earlier. In addition, MMP-2/-9 seems to have prognostic effect in AML [12]**.**Another study that measured the expression of MMP-2 in the Amyloid precursor protein (APP) which is prognostic significance in AML, the expression of MMP-2 revealed decreasing in the patients[17]**.**

Our finding Disargree with[6] because they were used Bone marrow CD34 to measured MMP-2 in the blast cell and also Real time PCR technique while present study use Enzyme linked Immunosorbent Assay (ELISA).

Table (1): Matrix Metalloproteinase 2 (Total MMP-2) concentration among patient and control in serum. **(P<0.01)

Total MMP-2	No.	Mean ±se	Range	P-value	T-test Value
Patients	50	3.815± 0.72	0.122-15.1	0.000	-7.49**
Control	50	10.636±0.558	7.3-18.9		

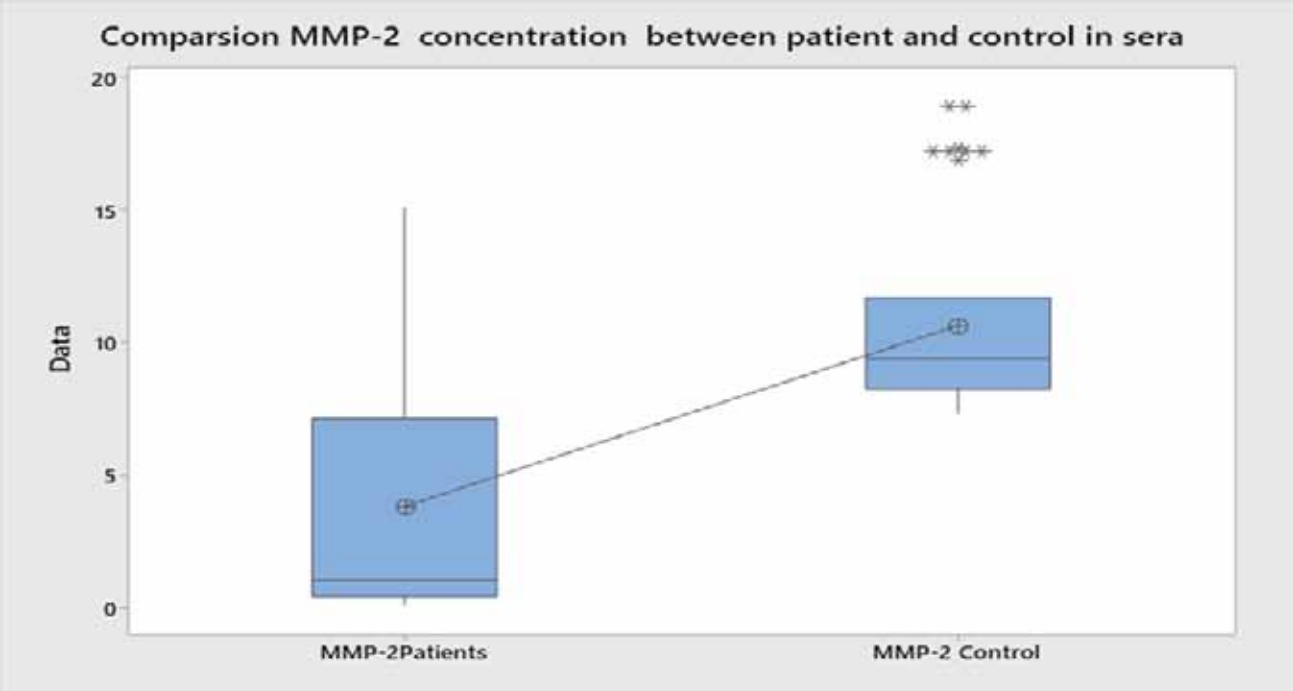

Figure (1) Matrix Metalloproteinase 2 (Total MMP-2) concentration among patient and control

The concentration of prostaglandin E2 in AML patient serum was (339.5± 60.8)while the concentration of prostaglandin E2 of the healthy control serum were (19.95±0.558) there were a highly significant differences between patient and control (**(P<0.01).** the present result was agree with previous reports **(9,24,30). Table (2) (Figure (2)**

The current result were agree with[22] who were showed there was increase in the level of PG E2 in the AML children compared with control .

Importantly, similar results were obtained [15] who were show >100-fold PGE2 more than healthy control

The tumor-promotive activity of PGE2 regulated by A vascular endothelial growth factor (VEGF) or cyclic monophosphate-dependent adenosines (cAMP) pathway which induces an activation of the proliferation of the cancer cell and has anti-apoptotic effects in various tissues [34]**.**

Table (2): Prostaglandin E2 (PGE2) concentration among patient and control in serum . **(P<0.01)

Total PGE2	No.	Mean ±se	Range	P-value	T – test Value
Patients	50	339.5± 60.8	45.3-1585.9	0.000	5.25**
Control	50	19.95±0.558	2.21-40.01		

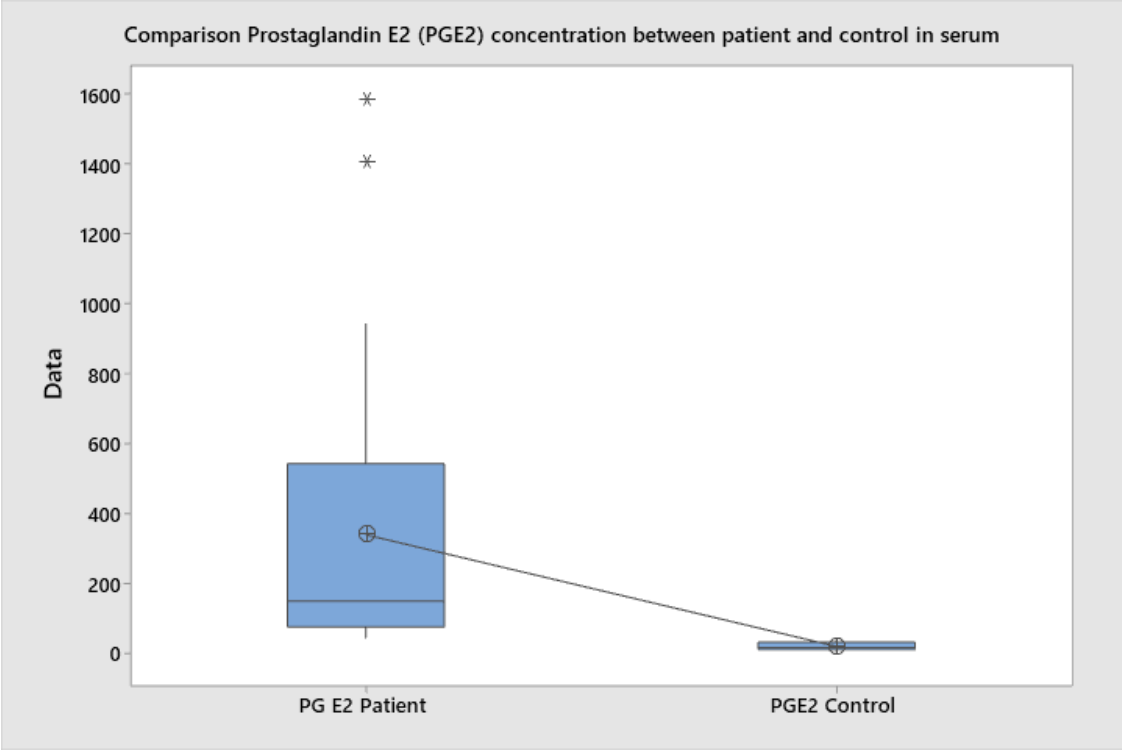

Figure (2) Prostaglandin E2 (PGE2) concentration among patient and control in serum

In the course of current analysis, we examined serum samples of a total of 50 patients with Newly AML(8%) (*n* =4), Partial remission AML(22%) (*n*=11), AML in complete remission (10%) (*n*= 5), Refractory (36%) (*n* = 18), and Relapse(24%) (*n*= 12).

The level of Matrix Metalloproteinase 2 (MMP-2) were decreased in the relapse (2.23±0.8 ng/ml), refractory (3.37±1.41 ng/ml),partial remission (3.57±1.54 ng/ml) and newly diagnosis patients (2.03±1.55 ng/ml) compared with healthy control (10.636±0.558 ng/ml) **Table (3).** The present data agree with [32] who were compared between AML-treated patients with intensive chemotherapy, the expression of MMP-2 was not different in resistant cases and in patients with complete remission

MMP-2 pretreated lower than level of MMP-2 post treated agreed with [3]However [23] who revealed the patient with acute lymphoblastic leukemia (ALL) patients, they found MMP-2 level were higher as compared to BM donors.

The pervious study were measured the MMP-9 level before treated with chemotherapy and after treatment they showed decrease in the level of matrix metalloproteinase in the patient with lung cancer [11].

While the concentration of Prostaglandin E2 were much higher in relapse patient (498±211 pg/ml) and also high in partial remission patients (347±132) and the level of prostaglandin E2 in refractory (291.2±86.4),complete remission (301±86.4) and newly diagnosis(246±140) were higher than human control (19.95±0.558) **Table (3)**. Although there is a scarcity of researches that is similar to the current research the current findings were agreed with [2] elevate of PGE2 that will lead to increases the activation of Tregs and participates in the development of Myeloid derived suppresser cell (MDSC) Such cells infiltrate the microenvironment of the tumor and dampen the immune response of the tumor by inhibiting the function of the T-cell effector, which in turn hampers immunity against cancer[24].

Table (3): AML patient Among All parameters and stages of disease

Parameters	Control	Newly(n=4)	Partial (PR) (n=11)	Complete (CR) (n=5)	Refractory (RF) (n=18)	Relapse (R) (n=12)
MMP-2±SE	10.636±0.558	2.03±1.55	3.57±1.54	8.93±1.89	3.37±1.41	2.23±0.8
PGE-2	19.95±0.558	246±140	347±132	301±86.4	291.2±86.4	498±211

Conclusion

The mean level of Matrix Metalloproteinase 2 (Total MMP-2) concentration serum was a statistically decreased in patients of AML as compared with control subjects($p<0.05$), furthermore The levels of Prostaglandin E2 (PGE2) concentration were significantly increased in patients with AML compared with healthy subjects (339.5± 60.8 pg/ml *vs.* 19.95±0.55 pg/ml) ($p<0.05$). the level of MMP-2 deceased and PG-E2 elevated with AML stages that were consider MMP-2 and PG-E2 was indictor for progression of AML disease **.**

Molecular Profile of Integrase gene *intI* and Carbapenem gene in *Aeromonas sobria* Isolates

Hawraa Natiq Kabroot AL-Fatlawy[1], Taghreed Abdul Al-Kareem Al-Makhzoomy[2], Mohammed Abdulaali Al-Hakeem[3]

[1]Ph.D. Dr. Academic(Molecular Genetics) in Dep. of Medical Laboratory Techniques, Al-Toosi University College, Najaf, IRAQ, [2]M.Sc. (Microbiology) in Laboratory Investigation department, Faculty of Science, University of Kufa, Najaf, IRAQ. [3]B.Sc. in Biology department, Faculty of Science, University of Kufa, Najaf, IRAQ

Abstract

The current study includes the detection of *Aeromonas sobria* isolates were obtained from total 157 samples involved the clinical samples (diarrhea samples) from patients suffering from diarrheal infections during the period from April 2017 to November 2017. at AL-Central Health Laboratory in Najaf governorate. These isolates were diagnosed by four method as (Culture method, biochemical tests, Vitek@2GN cards system and Polymerase chain reaction (PCR) technique). TheVitek@2GN cards system was the best method for diagnosis, which have led to isolate and diagnosis of 33 isolate. Multidrug resistance (MDR) of bacteria were detected by MIC testing and performed with the automated VITEK@2 GN/AST compact system. A clear variation was observed in their susceptibility to 13 antibiotics disks, these isolates of *A.sobria* were revealed resistance for some antibiotics such as Penicillin class Methicillin, Amoxicillin, Ampicillin, Penicillin (100%), and (91.6%) for Carbenicillin, and high rates of resistance (100%) to Cephalosporins that represented by Ceftazidime, Cefotaxime, Cefoxitin and Cefepime. The investigation of mobile genetic elements among isolates demonstrated that*A.sobria* have been Class I integron genes (class 1 integron represented by integrase *intI1,* and IMP genes).

Keywords: *Aeromonas soria, IMP gene, integrase intI1, Antibiotics and imipenem.*

Introduction

Aeromonas sobria are species of the genus *Aeromonas*, which belongs to the family *Aeromonadaceae* that received increasing attention opportunistic pathogens because of its association with both diarrheal and extra intestinal infection in human disease especially in children and persons with impaired immune system[1,2,3]. Multidrug resistance (MDR) was reported in the genus of *Aeromonas*[4]. *A.hydrophila*and *A.sobria*are anantibiotic resistant a variety of antibiotics have been used to treat infection caused by *A.hydrophila* and *A.sobria*. The high occurrence of (MDR) observed in *Aeromonas spp.*[5,6]. The antibiotic resistance genes that integrons capture are located on gene cassettes. *Aeromonas spp*. have been contain Class I integrin[7]. Integrons may be found as part of mobile genetic elements such as plasmids and transposons. Integrons can also be found in chromosomes. The aim of studyfor this purpose, the steps were: 1- Isolation and identification of *A.sobria* in clinical and in Najaf by VITEK@ 2 GN/ID card system. 2- Detection the Antimicrobial susceptibility of *A.hydrophila* and *A.sobria* isolates using antibiotics disks and MIC/AST. 3- Characterization of Class I integron and related mobile genetic elements (MGE) among MDR isolates. And determination of some MDR and β-lactamase resistance genes such as (bla_{IMP}).

Materials and Method

- **Identification of *Aeromona*:** Phenotypic properties were recorded on microscopic characteristics by

Gram's stain was used to examine the isolated bacteria for studying the microscopic characteristics such as gram reaction, shape, motile and the media that are used (TCBS agar; MacConkey agar and blood agar) for primary identification of *Aeromona*. Also Biochemical tests used Catalase test (3% Hydrogen Peroxide), Oxidase test, Indole Production test, Simmon's Citrate test and Motility test were all these tests and urease test result according to studies[8,9].

- **Identification of *Aeromonas* by VITEK@2 GN-ID System:** The identified *Aeromonas ssp* isolates were confirmed with the automated VITEK@2 compact system by using GN/ID cards. The GN ID card is based on established biochemical method (64 reaction) and newly developed substrates, measuring various metabolic activities.
- **Antibiotics susceptibility:** Minimum Inhibitory Concentration (MIC) antibiotics were used by VITEK@2/AST, such as (AST-GN084, AST-GN093 Card system), as mentioned in antibiotics disks were used 13 antibiotic of many class and sub-class antibiotics (Penicillins, Cephems, Monobactams, Nitrofurans, Quinolones, Ansamycin, β-lactamase, Carbapenem, Tetracycline, Aminoglycosides, Phenicols, Folate pathway inhibitors and Lipopeptide).

Results And Discussion

Isolation and Identification Culture and Biochemical Tests: The isolation and identification of *Aeromonas sobria* showed that only 33 isolate were positive based on the morphological characteristics of the colonies on TCBS, MacConkey agar, Aeromonas media and blood agar media These isolates were smooth yellow, shiny, flat, about 2-3 mm in diameter colonies on TCBS (Fig. 1), while they were small and pale colonies on MacConkey's agar when incubated for 24h. While microscopic examination of cultures showed that the bacteria were gram-negative slightly curved rods, non-spore forming cells, arranged as single or double of bacterium bacilli. The classification of *Aeromonas* has been confusing because of lack of matching between phenotypic and genotypic characteristics of species and multiple method that are required for accurate taxonomy[10].

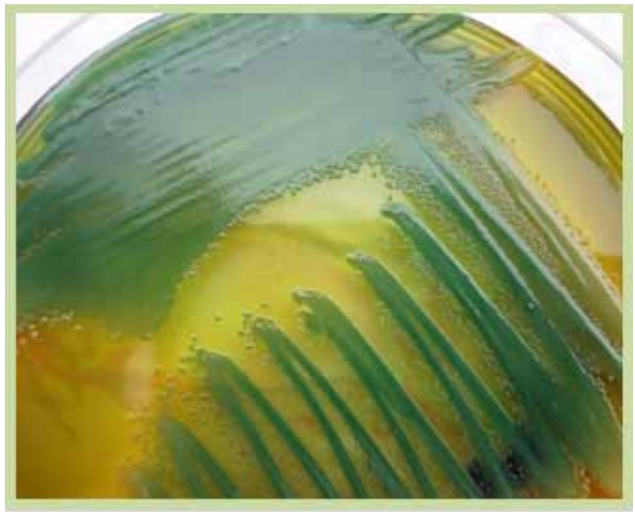

Fig. 1: *A.sobria* isolate on Aeromonas isolation agar and

On the other hand, the results of biochemical tests referred to that not all were positive to oxidase and catalase tests. The positive isolates were characterized with the ability to ferment the glucose only on KIA, so the isolates gave alkaline slant with acid bottom without H2S or CO^2 production. Also, isolates showed positive results to simmon's citrate and negative to urease test [Table 1]. According to these biochemical tests only 33 stool samples showed positive result as *A.sobria* . This result was predicted by previous studies[6,11,12].

Table 1: Biochemical tests for *Aeromonas*

No.	Tests	A.sobria
1	Oxidase test	+
2	Kligler iron agar	Alk/Acid with gas
3	Indole test	+
4	Citrate test	+
5	Methyl red test.	+
6	VP	+

The identification by VITEK@2 was performed with the automated VITEK@2 system using GN-ID cards which contained 64 biochemical tests. The results were demonstrated 33 *A.sobria* isolates were confirmed with ID message confidence level ranging excellent (Probability percentage from 94 to 99.7 %).

Molecular Identification by PCR Technique:

Antimicrobial Susceptibility Determination:

A. Minimum Inhibitory Concentration of Aeromonas: MIC testing was performed with the automated VITEK@2 GN/AST compact system. The results of the study revealed that all*A.sobria*isolates were resistant to minimum of many classes of antibiotics (MIC) to which they are tested. Hence, all isolates were considered to be multidrug resistant (MDR), revealed that the resistant of *A.sobria* isolates to Penicillins (Ampicillin, Amoxicillin/Clavulanic, Piperacillin and Piperacillin-Tazobactam) were recorded in 100% for all isolates . The resistance to β-lactam/β-lactamase inhibitor combinations was appeared in 100% of *Aeromonas* isolates. MDR of *A.sobria* isolates were represented by resistance to twelve class and sub class of antibiotic. All isolates appeared resistance to (Penicillin class) Methicillin, Amoxicillin, Ampicillin, Penicillin (100%), and (91.6%) for Carbenicillin. The study also revealed a high rates of resistance to Cephalosporins that represented by Ceftazidime, Cefotaxime, Cefoxitin and Cefepime were detected in (100%). Resistance to all β-lactam/β-lactamase inhibitor combinations includingAmoxicillin-Clavulanic acid and Pipracillin-Tazobactam (100%). The results of resistance isolates appeared high resistance to Imipenem (75%), Meropenem (77%) and Ertapenem (80%) of Carbapenem class, were effective against the majority of these isolates, these results agreed with other studies such as[4,13]**.** The human populations within these regions are at risk of exposure to antimicrobial resistant bacteria, and thereby disseminating antimicrobial resistance (ARGs) genes [14]**.**

Molecular Detection of Resistance and Integron Class I Genes: All *A.sobria* isolates were detected for the present of ESBL genes. The results revealed that isolates yielded amplification products with specific primers for types of extended-spectrum-β-lactamase(ESBL) and metallo-beta-lactamase (Carbapenem) antibiotics genes. All isolates in the present study were tested phenotypically of ESBL and Carbapenem production by MIC method and genotype. However, gene in the families only IMP were examined in the present study. Detection of these genes was performed by PCR technique. The results revealed that out of the 29 *A.sobria*isolates contained of genes 29 isolate *bla* $_{IMP}$(587 bp), *intI1*(497bp) *genes* as mentioned in [fig. 2] and [fig. 3]. Previous studies unquestionably established the role (>85% of isolates) of many *Aeromonas* spp. such as *A. hydrophila, A. Sobria, A.caviae*and *A. veronii*in diarrhea[4,15]. Deng *et al*[16] *confirmed that Aeromonas* strains containing multiple drug-resistance integrons, and these data suggests that surveillance for antimicrobial resistance of animal origin and responsible use of antimicrobials in aquaculture is necessary in these farms. Current results are agreed of *Aeromonas* produced class I integronsgenes with other studies[7,17,18].

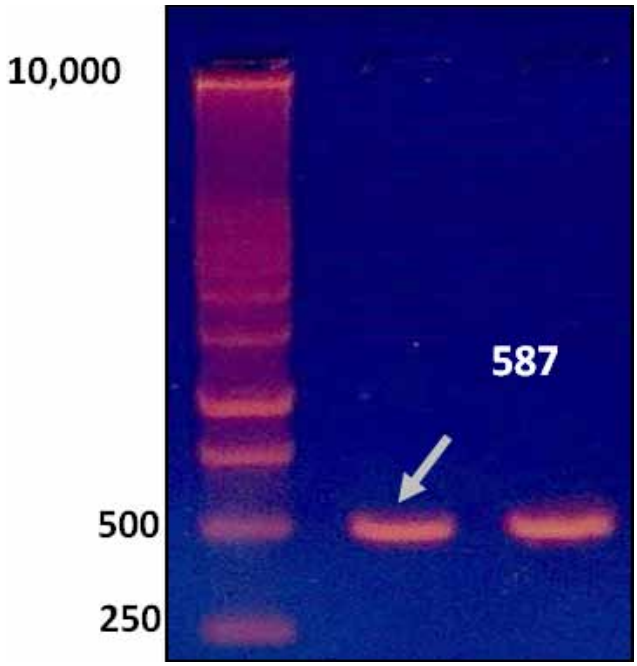

Fig. 3: Agarose Gel Electrophoresis (1.5%) of PCR products of *intI1*(497 bp) gene of .*sobria* isolates for (45) min at (100) volt.

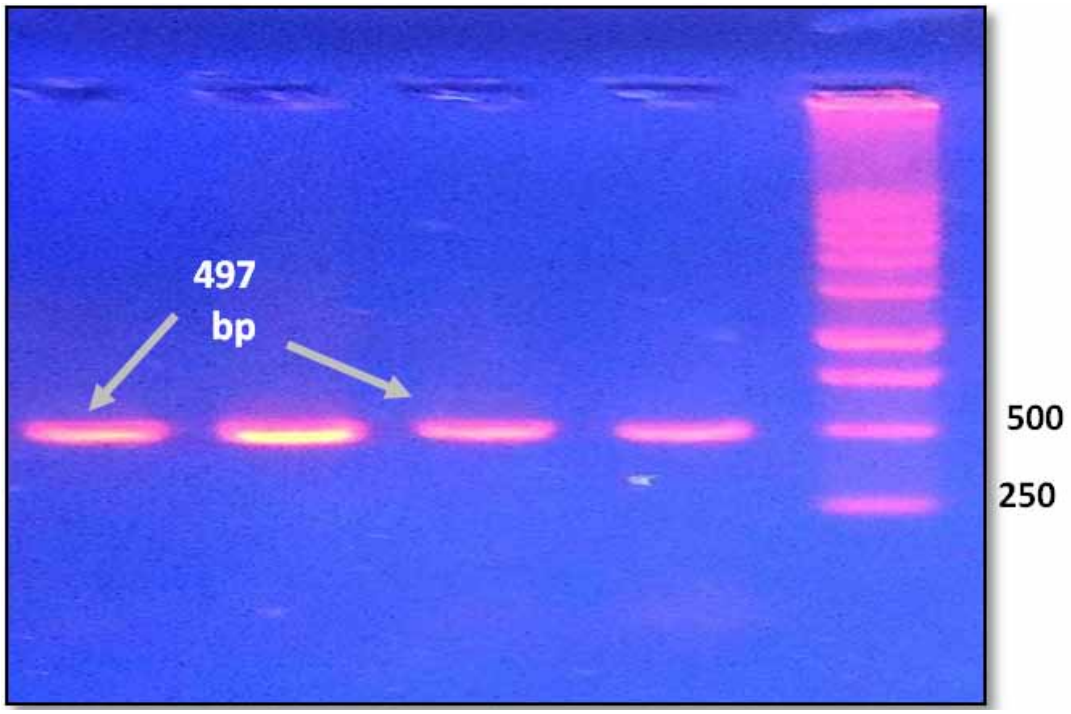

Fig. 2: Agarose Gel Electrophoresis (1.5%) of PCR products of IMP Genes (587bp) of *A.sobria* isolates for (45) min at (100) volt.

Conclusion

The frequency of *A.sobria* isolates in Najaf were higher among local clinical isolates. Identification by VITEK@2GN card system and Molecular techniques are necessary for detection of pathogenic bacteria among clinical isolates. Molecular characterization of Class I integrongenes, genetic elements (MGE) among MDR isolates were found in most *Aeromonas* isolates. *A.sobria*was multidrug resistance by shown a great emergence of MDR isolates among strains isolated and resistance to twelve class and sub class of antibiotic Methicillin, Amoxicillin, Ampicillin, Penicillin, Ceftazidime, Cefotaxime, Cefoxitin and Cefepime, Amoxicillin Clavulanic acid and Pipracillin-Tazobactam, Rifampin.

Comparative Study of Children with/without Iron Deficiency Anemia Based on Parents' Knowledge, Attitude and Practice in Basra/Al-Madinah City

Haydar Mohsin Abdulhussein[1], Jabbar Taresh Ahmed[2], Abbas Ali AL-Kinani[3], Faiz hussien ali[4], Rasha Mohammed Jumaah[5]

[1]Postgraduate Student Iraqi at Community Health Techniques, Health and Medical Technical College, Southern Technical University, Iraq, [2]Assistant Professor, Community Health Techniques, Health and Medical Technical College, Southern Technical University, Iraq, [3]Specialist in Epidemiology & Biostatistics, Wasit Health Department, Iraqi Ministry of Health, Iraq, [4]Specialist in Pediatrics Medicine, Al Madinah General Hospital, Basra Health Department, Iraqi Ministry of Health, Iraq, [5]Scolar Researcher, Specialist in Communicable Diseases, Wasit Health Department, Iraqi Ministry of Health, Iraq

Abstract

Background: Children under five years of age suffer from anemia is a common medical problem worldwide. Iron deficiency anemia is the most prevalent in infants and has proven to be a public health issue. Many studies have been conducted on anemia among infants but the scope of the studies focused on anemia prevalence with less emphasis on anemia knowledge and parental practice.

Objective: To explore the level of parental knowledge, attitude, and practice towards iron deficiency anemia.

Method: A cross-sectional study in the first taken 150 children that attended to Children's Counseling at Madinah General Hospital from these in the second case control study show only 30 children that effect with IDA and 30 children without IDA.

Results: In this study, the prevalence of anemia in less than two years is 46.7%. knowledge answers near half study sample with their children previously diagnosed with IDA was 16 (53 %), the attitude of parents about IDA between two groups not there is a significant relationship and most answers of parents with their children previously diagnosed with IDA was between Fair 17 (57%) and Poor 11(36%), not there is a smaller study in this article to refuse or accepted. Practices show a significant association between (case with IDA) and (control without IDA) because (65% poor) practice About IDA in the case in other side control was (26%) poor only About IDA in the differential in practice refer more vulnerable to the effect of children to IDA.

Conclusion: Anemia is prevalent in infants 24 months old with substantial differences in parents' knowledge and practices.

The world›s population – anemic, mostly because of iron Deficit [1]

Children under five years of age suffer from anemia is a common medical problem worldwide. Iron deficiency anemia is the most prevalent in infants and has proven to be a public health issue. Many studies have been conducted on anemia among infants but the scope of the studies focused on anemia prevalence with less emphasis on anemia knowledge and parental practice. In Iraq, iron deficiency (ID) prevalence in children under the age of five is 14.4%, and IDA prevalence is 6.8%. [2]

Aim of the Study: To explore the level of parental knowledge, attitude and practice towards iron deficiency anemia.

Method

1. **Study Settings:** In the Basra/Iraq, Children with clinical signs of undernutrition were randomly selected from the Children›s Counseling at Madinah General Hospital by a pediatrician and newborn specialist in the Al-Madinah areas, north of Basra Governorate, and laboratory investigation doing for him including hemoglobin (Hb) and serum ferritin measurement at nine months to 83 months.
2. **Study Design:** This is case control study.
3. **Data Collection:** Data was collected over three months, from 7st January to 18nd April, 2020. Data (using a structured questionnaire tool) was obtained from the parents of eligible infants through interview (face to face).
4. **Data Collection Tool:** The data collection tool was based on medical references and previous researches The content validity was tested via ten pediatric consultants working in Ministry of Health. The questionnaire is composed of three parts: the first part is about the sociodemographic data of the parents. The second part includes questions to explore the knowledge of parents about iron deficiency anemia,

Part Two: Laboratory measurements

This part of the questionnaire consists of questions related to child-related measures such as hemoglobin level, serum ferritin level according Normal findings [3]

Hemoglobin = 1-6 years: 9.5-14 g/dL

Ferritin = Newborn: 25-200 ng/mL

≤ 1 month: 200-600 ng/mL

2-5 months: 50-200 ng/mL

6 months-15 years: 7-142 ng/mL

Iron deficiency was defined as serum ferritin levels of below 31 ng/ml, while iron-deficiency anemia was defined as hemoglobin of less than 11 g/dl and serum ferritin of less than 31 ng/ml [4]

5. **.Exclusion criteria:** Children with hereditary blood diseases: thalassemia, sickle cell anemia and macular (G6PD) glucose 6 phosphate dehydrogenase deficiency excluded from this study.
6. **Measures and Parameters of KAP study**

Regarding the Knowledge: The scale of the three levels was rated on the 3 points (likert respondent scale) it was scored as a scoring of agreed about by assigning a score of (3) for yes, (1) for (no) and score of (2) for I don't know.

Number of questions: 27

Minimum =27, Maximum = 81, Medium =64

The medium was calculated for each participant and those score below the medium (score < 64) consider poor score, (score > 64) good and acceptable score.

Questions was about Do you know what iron deficiency, symptoms of iron deficiency, causes of iron deficiency, iron rich food, the negative effects of iron deficiency, the source of your information about iron deficiency anemia, Tea, coffee and milk are among the substances that reduce the body's proper absorption of iron, A balanced diet should contain the following nutrients, Iron deficiency anemia is one of the most common types and dietary anemia types.

Regarding Attitude: A scoring of attitude divided into two score agreed about by assigning a score of (2) for the answer by (agree), (1) for the answer by (disagree).

Number of question: 10

Minimum =10, Maximum = 20, Medium =15

The medium was calculated for each participant and those score below the medium (score <15) consider poor score, (score > 15) good and acceptable score.

Attitude was about are you with a child drinking tea with a meal, the child to drink iron drink after eating,

iron drink children before eating, the child eating fruits regularly, eating red meat, eating ready-made juices, drinking cola and soft drinks, eating crackers (chips and derivatives), eating breakfast daily, eating lunches daily and eating dinner every day.

Regarding Practices: A scoring of practices agreed about by assigning a score of (2) for the answer by (yes) and (1) for the answer by (no).

Number of question: 13

Minimum =13, Maximum = 26, Medium =24

The medium was calculated for each participant and those score below the medium (score <24) consider poor score, (score > 24) good and acceptable score.

Practice question was about does the child have tea, drink tea with food or immediately after eating, eat vegetables (spinach, parsley, radish, basil), eat fruits regularly, eat red meat, eat chicken, eat eggs, eat ready-made juices, drink cola and soft drinks weekly, eat crackers (chips and derivatives), eat breakfast daily, eat lunch daily and eat dinner every day

Statistical analysis: Descriptive, frequencies, central tendency, ANOVA, chi-square, correlation have been used to clarify the relationship between the research variables. The Statistical Package for the Social Sciences (SPSS) version 24 was used in the statistical analysis and treatments.

The significance of different percentages (qualitative data). Statistical significance was considered whenever the P value was equal or less than 0.05.

Results

Data are collected orally by an interviewer using a standardized questionnaire. The age group of children of the study was 46.7 between (9-23) month was suffering from IDA, and 43.3 control group, 72-83 month with high significant association between age group and study sample. This differential may be because of a split of age group to categories.

In another variable from DGDVs show not has the association between group (case & control) but only was weak a significant association in variable crowding index P.Value < 0.05 half of the crowding index case was (2.1- 4) and in control was (4.1- >5) person per bed in the room.

KAP study shown in figure (1) compressed between parents of children that attend to children's constitution asked about KAP about IDA.

Show in figures of knowledge does not have a significant association because the answer to the question nearing.

Also in figure attitude show non-significant association P. Value > 0.05 because their attitude about IDA was smaller PV (0.024), but figure practice show a significant association between (case with IDA) and (control without IDA) because (65% poor) practice About IDA in the case in other side control was 26%poor only About IDA in the differential in practice refer more vulnerable to the effect of children to IDA.

In table (1) show correlations between DGVs and KAP study show a positive association between practices age group, occupation of father, and knowledge (P. Value < 0.05) respectively, also show a significant association between knowledge and SES (P.Value < 0.05) and gender (P.Value < 0.05).

With IDA	Without IDA	P. Value

**Correlation is significant at the 0.05 level (1-tailed).

Discussion

Our study showed that the prevalence of anemia in infants aged 9 months who took part in this research was 46.7%, which is in concordance with previous statistics and local studies Al-jamri A. [5]

Residence distribution of the sample mostly lives in rural, because the hospital locating in rural and most of attended to hospital from this area. Show the high affected with a decrease in was 28 (93.3) from the total study, this accepted with Saaka M. and Gebreweld A.[6,7] In your articles, it was found that children with anemia in rural and urban areas had a high rate of (73.0) & (59.5) respectively**.**

Occupation of the parent that have children affected with IDA most distribution in side father was unemployed 18 (60.0), in other side occupation of the mother was housewives 60 in total study sample, this agree with Gebreweld A. [7]In his article it was found that occupation a high percentage among housewives was (43.1**).**

Overcrowding has affected many health problems one of thesis nutrition status of children show in our study crowding index most distribution between (2.1-4) that has children affected with IDA was 15 (50.0), this disagree with Abdel-Rasoul G. [8] Most distribution is between ≤ 2 they have IDA 36 (76.6).

This study was mostly on children with low-socioeconomic status. Low socioeconomic status has been known to be a risk factor of IDA . However, we found that our prevalence of IDA is 18 (60.0) suffering from low scale of S.E.S this study accepted with Andriastuti M. [9] The overall prevalence of IDA in them study was 14.0 .

Knowledge: Show in our results knowledge answers near half study sample with their children previously diagnose with IDA was 16 (53) this results accepted with Al-jamri A. [5] 32.5% of parents correctly answered half or more of the questions regarding IDA complications.

Attitude: Funding attitude of parents about IDA between two group not there is significant relationship and most answers of parents with their children previously diagnose with IDA was between Fair 17 (57%) and Poor 11(36%), not there is smmiller study in this prochect to refuse or accepted .

Practices: Show a significant association between (case with IDA) and (control without IDA) because (65% poor) practice About IDA in the case in other side control was 26%poor only About IDA in the differential in practice refer more vulnerable to the effect of children to IDA, this result different with Abdallah R. [10] demonstrates the mean values of food habits of the anemic cases and the normal control. It can be noticed that there were no statistically significant differences between cases and the normal control in food habits as, the *P* value > 0.05.

Conclusion

This finding from this study suggested that PARENTS of children had less awareness of iron deficiency anemia and significant difference in practice between groups of study.

Practice will play a significant role in enhancing anemia and positive correlation between Knowledge, occupation of father, and age group with practice towards iron deficiency anemia.

Abstract

The study aimed to evaluate the beneficial effect of allogenic omental graft on esophageal healing in dogs. Twenty healthy male adult dogs were used they were randomly divided into two equal groups (control group 10, treated group 10). Under aseptic technique 4 cm skin incision was made in the midline of the cervical(ventral) of animal by scalpel, after that the incision was sutured immediately by polyglycolic acid suture materials 0.3 USP used simple continous technique, and the omental graft extracted from same animals by laprotomy piece of greater omentum was then placed over the oesophagotomy incision of the experiment group and secured in place with tacks sutures, In the control group, the esophagotomy suture line was left without graft. Esophageal healing process follow up 1,2 and 3 weeks post operation by histopathological examination, the result display in treated group on the first week post operation development of collagen and lamina properia contain congested blood vessels with epithelial regeneration. 2 weeks post operation show the epithelium of the mucosa of the esophagus was formed by hyperplasia of squamous cells. The surface of these epithelia was covered by keratin with present of bundle of collagen and fibroblasts. 3 weeks post operation showed the epithelium of esophagus was covered by keratin, with the presence of blood capillaries and also, there was lymphocytic infiltration in the lamina properia with RBC. The tunica muscularis was consisting of skeletal muscle fibers, inner longitudinal, and outer circular, proliferation of fibroblast with deposition of collagen, while in control group histopathological examination in the first week show The epithelium of the esophagus was stratified squamous with the presence of keratin on its surface, 2 weeks post operation show The mucosa of the esophagus consisted of stratified squamous epithelium with a keratin layer on its surface. The lamina properia was composed of loose connective tissue with infiltration of many WBC and blood vessels, 3 weeks post operation show the basal layer of epithelium had many folds which are interdigitation with the underlying lamina properia, which appeared loose connective tissue with few numbers of fibroblasts and lymphocytes, the healing of treated group better than control group.

Introduction

Esophagectomy remains one among the foremost strict surgical procedures with considerably associated morbidity and mortality conjugation leak when esophagectomy remains a vital explanation for patient morbidity and impaired quality of life [(14)]. The treatment of muscle system disorders, such as, inherent anomalies and muscle system cancer, ends up in circumferential, full-thickness, extended section loss of the muscle system. Internal organ pull-up conduits or colon interpositions are wont to re-establish the sodium thiopental continuity. However, the utilization of those muscle system substitutes will cause numerous surgical morbidities and mortality [(7,8)]. Muscle system injuries like partial-thickness defects from membrane resections may result in pathology and refractory strictures. Similarly, full-thickness patch defects like perforations will cause leaks and fistulae. Esophagectomy finished malignant and benign conditions will cause full-thickness, long-segment, circumferential defects. These need colon or internal organ conduits to take care of sodium thiopental continuity resulting in poor quality of life [(16)]. However,

involved in conjugation leak anatomic factors like a scarcity of membrane, inadequate blood offer, and fragile many factors might contribute to the high complication rate, together with lack of a membrane, the segmental nature of the blood offer, lack of peritoneum, the constant motion of swallowing and respiration and tension at the surgical web site [10]. Additionally muscle layers lying longwise that build it tough to realize watertight stitching of the esophagogastric conjugation [6]. numerous ways examining a way to stop conjugation leak are delineated antecedently. These techniques embrace buttress the conjugation with encompassing tissue like peritoneum, pleura, or pericardiac fat [5]. Therefore Augmentation of oesophagotomy web site with peritoneum, serous membrane, native muscle flap, abdomen or gut will aid healing by supporting protection and revascularizing the surgical web site [11].

Materials and Method

Twenty male adult mixed breed dogs, 12 to 14months old and weighing 14-18 kg, were used. Health status was determined by physical and hematological examinations. The dogs were randomly designed to two groups experimental and a control group, ten dogs in each group. All ethical considerations using animals were considered, and the experimental protocol was approved by the Ethics Committee of Basrah University. The animals were premedicated with 0.02 mg/kg atropine (KELA Laboratoria, Belgium) intramuscularly. After 10 minutes, a mixture of 5mg/kg, of 2% Xylazine Hydrochloride (VMD-Belgium), and 15 mg/kg, of 10% Ketamine (Alfasan-Holland), were given intramuscularly as general anesthesia. After induction of anesthesia, surgical preparation was carried out in a standard method. In this study, all dogs underwent esophagotomy and laparotomy operation. To perform the cervical oesophagotomy, an incision was made at the midline on the ventral surface of the neck, beginning at the larynx and extending caudally to the manubrium. After separation and retraction of local muscles, the trachea was retracted to the right, and the cervical esophagus was exposed. After this, a stab incision was made into the lumen of the esophagus, and a 4-cm linear incision was extended longitudinally. The surgical site was rinsed using normal saline and the oesophagotomy incision was closed using 3–0 polyglycolic acid (Demetech, England) with a simple continuous pattern in both groups. To perform the laparotomy, the abdominal cavity was approached through a 7–10-cm ventral midline incision midway between the umbilicus and pelvic inlet. A 2×2-cm2 piece of the omentum was isolated by two ligatures and cut free from the remaining parts. This piece of greater omentum was then cut and placed over the oesophagotomy incision of the experiment group and secured in place with tacks sutures. In the control group, the esophagotomy suture line was left without graft, and the isolated omentum was discarded. Finally, all surgical sites were closed routinely. Postoperative management consisted of withholding of oral intake for 24 h, and give all animals soft food during period of experiment, antibiotic (ceftiofur-Vietnam), at dose 0.1 mg/kg, IM, for 3 days postoperatively).

Results

Clinical Evaluation: Based on the clinical examinations, no significant postoperative complications such as dysphasia, regurgitation, and vomiting were observed in any of the dogs during the study. All dogs had incisional swellings to some degree which resolved in a few days. All dogs were depressed and lost their appetite for 48 h post-surgery and regained their appetite after that. They were fed with liquid food and gruel during the first seven days after surgery and then gradually returned to their regular diet until the end of the study. All animals remained healthy throughout the study.

Macroscopic Evaluations: The macroscopic assessment of the surgical site revealed that in all dogs, the esophagus adhered to the surrounding soft tissue, and there was no noticeable difference in the extent of adhesion between the two groups. No complications such as infection, dehiscence, stricture, and fistula were observed in the surgical site of all dogs. In the experiment group, the greater omentum was completely attached to the incision site.

Histopathological Results in Control Group:

7 day: The epithelium of the esophagus was stratified squamous with the presence of keratin on its surface. The lamina properia was containing blood vessels with blood congestion surrounded by lymphocytic infiltration, which also extended along the lamina properia. The muscular coat formed by skeletal muscle fibers (fig. 1).

14 day: The mucosa of the esophagus consisted of stratified squamous epithelium with a keratin layer on its surface. The lamina properia was composed of loose connective tissue with infiltration of many WBC and blood vessels, and the submucosa was continuing with

lamina properia. The muscular coat was skeletal muscle fibers arranged into two layers, inner longitudinal and outer circular direction. The tunica adventitia was loose connective tissue with blood vessels and wbc.(fig.2).

21 day results: The epithelium of the esophagus was stratified squamous epithelium with strands of keratin on its surface. The basal layer of epithelium had many folds which are interdigitation with the underlying lamina properia, which appeared loose connective tissue with few numbers of problasts and lymphocytes (figure 1), which these cells extended to the submucosa. The muscular layer was formed by a bundle of skeletal muscle fibers with the presence of many lymphocytes in between these muscle fibers.(Fig2,fig 3). The tunica adventitia was containing loose connective tissue fat cells and blood vessels, which appeared engorged with a moderate amount of blood.

Histopathological Results in Treated Group: The histopathological evaluation on day 7 shows the epithelium of the esophagus was stratified squamous with the presence of keratin on its surface. The keratin in certain areas was desquamated from the surface of the epithelium. The lamina properia was containing loose connective tissue with the presence of congested blood vessels, and individual WBCs were scattered in this area. The skeletal muscle fibers were encircling the esophagus. There was an area of this muscle containing atrophied skeletal muscle fiber with the presence of RBC in between skeletal muscle fibers. These skeletal muscle fibers were surrounded by collagen fibers (4).

On day 14. The epithelium of the mucosa of the esophagus was formed by hyperplasia of squamous cells which present with increasing of its thickness. The surface of these epithelia was covered by keratin with present of bundle of collagen and fibroblasts. The lamina properia was infiltrated with heavy population of lymphocytes and other wbc with many blood capillaries and larger congested blood vessels. The muscular coat was formed by skeletal muscle fibers, these was an area was devoid for these muscle but replaced by collagen fibers of skeletal muscle and many blood capillaries without blood, also present of many lymphocytes and plasma cells (fig. 5).

On day 21. The epithelium of esophagus was covered by keratin. The lamina properia was contained many congested blood vessels, with the presence of blood capillaries and newly formed vessels. Also, there was lymphocytic infiltration in the lamina properia with RBC. The tunica muscularis was consisting of skeletal muscle fibers, inner longitudinal, and outer circular. (fig. 6).

Discussion

The cervical approach was chosen in this study because we believed it is the easiest way to reach the esophagus. Trans-abdominal approach and thoracotomy in dogs are technically very difficult and accompanied by high morbidity [9]. In esophageal surgery, there is a higher risk of complications than in any other portion of the digestive tract [10,11]. One explanation could be that mesothelial cells are needed to promote anastomotic healing [9, 12]. In the current study, the addition of NOA to the esophageal suture line in an extra-abdominal position might have provided the necessary mesothelial cells and consequently promote healing. Some surgeons decided to use the pedicle omentum transposition for reinforcing the anastomotic suture line to reduce the incidence of leak significantly after esophagectomy and to decrease the morbidity and mortality of the procedure(11). The well-vascularized flap of omentum provides oxygen and nutrient for improving healing. Moreover, the omentum delivers vascular endothelial growth factor and potent angiogenic growth factor (3); this substance gives the ability to accelerate a neovascularization cross anastomosis line (13). The exact mechanisms are not completely understood, and there is some evidence to suggest that neovascularization increases through a process that is mediated by a lipid angiogenic factor liberated by the omentum[14]. Goldsmith et al. [15, 16] described the angiogenic properties of the omental lipid factor and its ability to increase revascularization and neovascularization. Accordingly, in our study, it has been postulated that the transplanted NOA induced neovascularization, which is beneficial for esophageal suture line reinforcement [9], possibly through the release of its lipid angiogenic factors (particularly vascular endothelial growth factor, VEGF). Nevertheless, it should be noted that we did not use more rigorous, accurate method, such as immunohistochemistry, to quantify neovascularization. Another possible role for the transplanted NOA in our study might be related to its mechanical function. As a matter of fact, an explanation for the impaired healing of cervical esophagotomies is its close proximity to another fresh wound. Collagenase levels might be higher in such an environment leading to the weaker suture line and, therefore, leakage [9]. Hence, we assume that NOA, as a mechanical covering, could keep esophagotomy suture line away from more superficial fresh wounds in the region. Furthermore, it has been presumed that the transplanted NOA played another role as a space-occupying structure, exerting its enhancing function by diminishing regional dead

space from observation of experimental animals in post-operational animals did not exhibit any signs of anastomosis leak, and when euthanized the animals to take the specimen, it showed that's all anastomotic site was normally healed without any dehiscence this study agree with [19]. Also, all animals have no adhesion and stricture this agree with [17] who showed no any adhesion or stenosis at the site of anastomosis that used omental pedicle, but its record increase in the thickness of esophagus at the anastomosis site and it related with the presence of omental pedicle. And disagree with [18] that refer not to happen stricture in his study when used omentoplasty with diaphragmatic muscle in esophageal reconstruction. Our study 21 days post-operation histopathologically showed formation of fibrous connective tissue with infiltrated of fibroblast this agree with [19] that refer in histopathological result showed the formation of fibrous connective tissue in adipose tissue of omentum which infiltrated by inflammatory cells at 15 days post-operation in the treated group.

FIBMS, Congenital Bleeding, Children Welfare Hospital, Medical City

Abstract

Case control study was used,with Glanzmann's thrombasthenia (GT) patients (n=15) and healthy individual control (n=20).

It was successfully identified three SNP in *ITGB3* gene by using PCR technique and direct sequencing . The first SNP c. * 1479T> C (rs115310198) was presented with three genotypes (TT, TC and CC). The genotype frequencies of TT in control group (87.6 vs. 95 %) show non-significant difference (p>0.05) compared with GT patients . It was also noticed the frequency of mutant allele (*C*) revealed non-significant difference (p > 0.05) in GT patients compared with controls group (13.3 vs. 2.5%; OR = 6; EF = 0.03; 95% C.I. = 0.65 to 55.05) that mean (*C*) allele is risk factor associated with GT patients .

The c.*713A>G (rs2317676) was given with three genotypes (AA, AG and GG) . The frequencies of these genotypes show non-significant difference (p>0.05) between control and GT patient,while the mutant allele (*G*) show non-significant difference (p > 0.05) in GT patients compared with controls group (16.6 vs. 5%; OR = 3.8; EF = 0.4; 95% C.I. = 0.70 to 20.63) and it was risk factors of patient GT. The c.*1016T>A (rs3809865) showed three genotypes (TT, TA and AA) with two alleles (*T* and *A*). The frequencies of these genotypes TT (87.6 vs. 85 %), TA (6.6vs. 15 %) and the third genotype AA (6.6 vs. 0%) show non-significant difference (p>0.05) between control and GT patient but the genotype (AA) (OR= 4.24) was considered as risk factors with GT patients . It was also found the mutant allele (*A*) revealed non-significant difference (p > 0.05) in GT patients compared with controls group (10 vs. 7.5%;OR = 1.37; EF = 0.11; 95% C.I. =0.26 to 7.14). (*A*) allele(OR = 1.37) is positively associated with GT patients and negatively associated with healthy subject .

Introduction

Glanzmann'sthrombasthenia (GT) can be inherited in an autosomal recessive manner[1,2] or acquired as an autoimmune disorder[1,3]. GT is an abnormality of the platelets in which the platelets contain defective or low levels of integrin $\alpha_{IIb}\beta_3$ formerly known as glycoprotein IIb/IIIa (GpIIb/IIIa)which is a receptor for fibrinogen. As a result, no fibrinogen bind of platelets to other platelets can occur, and the bleeding time is significantly prolonged[3]. The Clinical manifestations of GT including lifelong bleeding, menorrhagia, gastrointestinal bleeding, and easy fall injury[4].

The prevalence of GT is markedly different among different ethnic groups, indicating that the difference in

e-mail: dr.haidarkareem@gmail.com

genetic background contributes to GT susceptibility, so recent genome-wide association studies reported strong and reproducible associations of multiple genetic variants in *ITGB3*([MIM] 173470)gene with GT susceptibility (Gabriele, Canali*et al*. 2019).

The *ITGB3* (Integrin Subunit Beta 3) is a protein coding gene. The *ITGB3* protein product is the integrin beta chain beta 3. Integrins are integral cell-surface proteins composed of an alpha chain and a beta chain. A given chain may combine with multiple partners resulting in different integrins. Integrin beta 3 is found along with the alpha IIb chain in platelets. Integrins are known to participate in cell adhesion as well as cell-surface mediated signalling(5).

By demonstrating the response to phorbol esters, various other factors and biological processes can regulate the expression of β3 and control the expression of β3 at the transcription level. (6).Most commonly, the expression of GPIIb/IIIa on the surface of platelets is very low or absent, which is caused by mutations that lead to reduced mRNA stability or defects in post-translational processing (7).

The molecular and functional characterization of the mutations has provided important insights to the better understanding of the biosynthesis and structure-function relationships of the GPIIb/IIIa complex with the disease. It also adds important knowledge about the biology of other molecules of the integrin family (8, 9).

Genetic testing in GT patients is very important in the quality of life of the affected individuals and it facilitates prenatal diagnosis (PND) or pre-implantation genetic diagnosis (PGD) for at-risk families. The identified mutations will span the current database of the mutations of GT, so this study aimed at identifying mutations in *ITGB3* gene associated with GT in sample of Iraqi patients.

Materials and Method

Subjects: Fifty two GT patients were enrolled in the case control study during the period of March 2019 - September 2020. these Patients suffering from dysfunction of platelets were taken from iraqi populations with ages range from 2 to 50 years including 30 woman and 22 man from pediatric teaching hospital in Baghdad city . Sixty healthy Iraqi population samples were collected as a control group, whose ages ranged between 3 and 50 years, including 30 woman and 30 men.

Sample Collection: From each participating subject, 5 ml of venous blood was collected using 5ml disposable syringe. The blood was distributed into two aliquots. For the first, 3 ml of blood was dispensed in plain tube, and after clotting, the tube was centrifuged (2000-3000 rpm for 20 minutes) to collect serum. The serum was distributed into aliquots in 0.5ml eppendorf tubes, and the tubes were used to detection of human Platelet Membrane Glycoprotein IIBIIIA (also known as GPIIb/IIIa) in serum. The remaining blood (2 ml) was dispensed in EDTA tube, and frozen at -20 C until extraction of DNA for single nucleotide polymorphism (SNP) genotyping of *ITGB3* gene .

Measurement of Glycoprotein IIBIIIA Serum Levels: The quantitative of human Platelet Membrane Glycoprotein IIBIIIA was assessed in serum of GT patients and controls by means of ELISA (enzyme linked immunosorbent assay) principles. The assessment was carried out by using Human Platelet Membrane GPIIb/IIIa ELISA Kit that was produced by bioassay technology laboratory Company (china.), and the manufacturer instructions were followed. The sample results were calculated by interpolation from a standard curve that was performed in the same assay as that for the samples by using standard curve fitting equations for GPIIb/IIIa.

DNA isolation: Fifteen patient samples were selected based on the results of the ELISA examination and clinical signs and beside Twenty healthy individual subject were used as control group . Genomic DNA was isolated from blood sample for fifteen patient and twenty healthy subjects as control group according to the protocol of kit (ReliaPrep™ Blood gDNAMiniprep System, Promega).

Primers and optimization of PCR reaction: Regions of *ITGB3* gene were selected and amplified by PCR using primers (designed by the program PRIMER3) . PCR reaction system contained 12 μM of Master Mix, 10 μM each of oligonucleotide primers, 8.5μM Nuclease Free Water, 2 μM Taq DNA Polymerase . Thermocycling conditions of primers *ITGB3* -(F5`-TCCATAGCACCTCCACATA-3` and R5`-GGGTTTGGAGAGAGGATAGA-3`, and primers -F5`-TGAGCAGGTGTTCTTCATTAC-3` and -R5`-CTGTGGCCTCTCAGATTAAAG-3`) were as follows: an initial denaturation at 95 °C for 5 min, followed by 30 cycles of denaturation, annealing, and extension at 95 °C for 45 s, 60 °C for 45 s, and 72 °C for 45 s Respectively.

A final extension step (72 °C, 7 min) was performed at the end.

Direct Sequencing analysis: PCR products were directly sequenced using by Macrogen Corporation of Korea, and the results were analyzed using a genious program. according to the manufacturer's protocol. The samples were then run on the ABI3730XL genetic analyzer (TF). The sequence is compared with the cDNA sequence of the human genome and gene, and its accession number is *ITGB3* (NM:000212, NC:000017).

Statistical analysis: Allele frequencies of *ITGB3* gene and significant departure from Hardy-Weinberg (H-W) equilibrium were calculated using H-W calculator for two alleles, which is available free online at (https://wpcalc.com/en/equilibrium-hardy-weinberg/) . A Significant differences between the observed and expected frequencies were assessed by Pearson's Chi-square test (10). Alleles and genotypes of SNPs of *ITGB3* gene were presented as percentage frequencies, and significant differences between their distributions in GT patients and controls were assessed by two-tailed Fisher's exact probability (P). In addition, odd ratio (OR), etiological fraction (EF) and preventive fraction (PF) were also estimated to define the association between SNPs GPIIb/IIIa alleles and genotypes with the disease, and these estimations were calculated by using the WINPEPI computer programs for epidemiologists[11].

Result

Form total of fifty-two patient with dysfunction of platelets ELISA test show fifteen patients with GT disease.

The product of PCR amplification was showed after staining with ethidium bromide, Where a main band (904bp in length) appeared on the gel, representing the amplification of the restriction region of the *ITGB3* gene from chr17: 47310522-47311425, and the amplification between chr17: 47311191-47312137 was showed a region which represented (947bp) on the gel (Figure 1).

The direct DNA sequencing result reveald three mutations were found (c. * 1479T> C, c.*713A>G, and c.*1016T>A) of an *ITGB3* gene .

The c. * 1479T> C (rs115310198) mutation, replace the nucleotide *T* at chr17:47311683 (GRCh38. p12) with *C*, which is located in the 3′UTR region of the integrin β3 gene(figure 2). The genotyping of c.*713A>G (rs2317676) changed A>G in three samples (one homozygotes and two heterozygotes) of *ITGB3* gene chr17:47310917 (GRCh38.p12) show in (figure 3) . c.*1016T>A (rs3809865) is located in the 3′UTR region of the *ITGβ3* gene, and T> A changes at position chr17:47311220 (GRCh38.p12) (figure 4) .

The genotype distribution of these three variants is consistent with Hardy-Weinberg balance (P>0.05). The SNP c.*1016T>A (rs3809865) at position-chr17:47311220 (GRCh38.p12) was presented with two alleles (*T* and *A*) and three genotypes (TT, TA and AA). These genotypes showed deviation from HWE in GT patientsand control group respectively, because there was a significant difference between the observed and expected genotype frequencies ($p \leq 0.05$). Comparing GT patients to controls revealed that genotype frequencies of TT (87.6 vs. 85 %) and TA (6.6vs. 15%), while the third genotype (AA) was observed with a frequency 6.6 vs. 0% in patients and control group respectively, The genotypes AA,AT and TT in control group was non-significant difference (P>0.05) compared to GT patient but the genotype (AA) (OR= 4.24) was considered as risk factors with GT patients .It was also noticed the frequency of mutant allele (*A*) show a non-significant difference ($p > 0.05$) in GT patients compared to controls (10 vs. 7.5%;OR = 1.37; EF = 0.11; 95% C.I. =0.26 to 7.14) that mean (*A*) allele(OR = 1.37) is positively associated with GT patients and negatively associated with healthy subject, while in the control group the frequency of (*T*) allele show a non-significant difference ($p > 0.05$) compared to GT patients (90 vs. 92.5%; reciprocal OR= 1.37;EF = 0.71; 95% C.I. = 0.14 to 3.80) . In this case the (*T*) allele associated with healthy subject, but in GT patients group was negatively associated with reciprocal OR= 1.37 (Table).

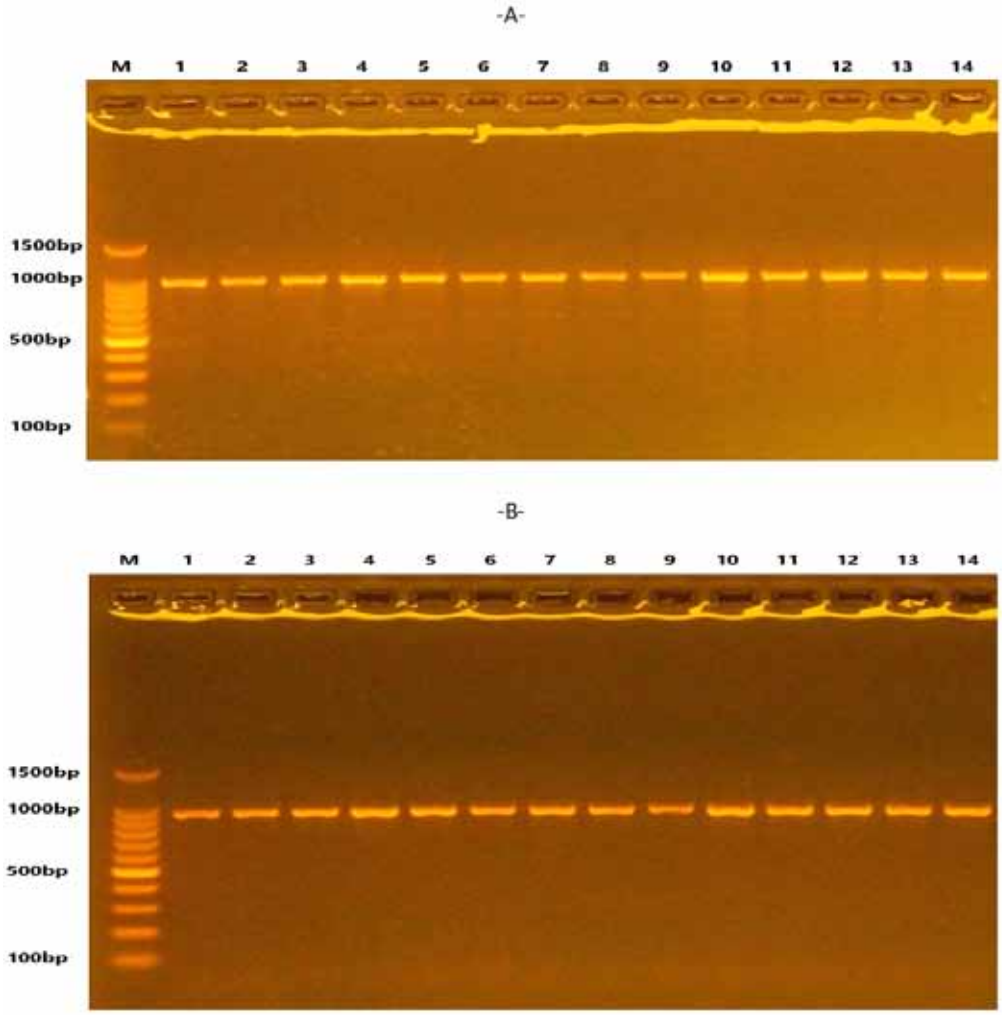

Figure 1 : The amplicon for *ITGB3* gene : A- from chr17 :47310522-47311425 which contains part from 3`UTR of GT patients with band have 904 bp . B- from chr17: 47311191-47312137 which contains part from 3`UTR of GT patients with band have 947 bp . The 2% agarose gel was assay by using at 7C voltages for one hour

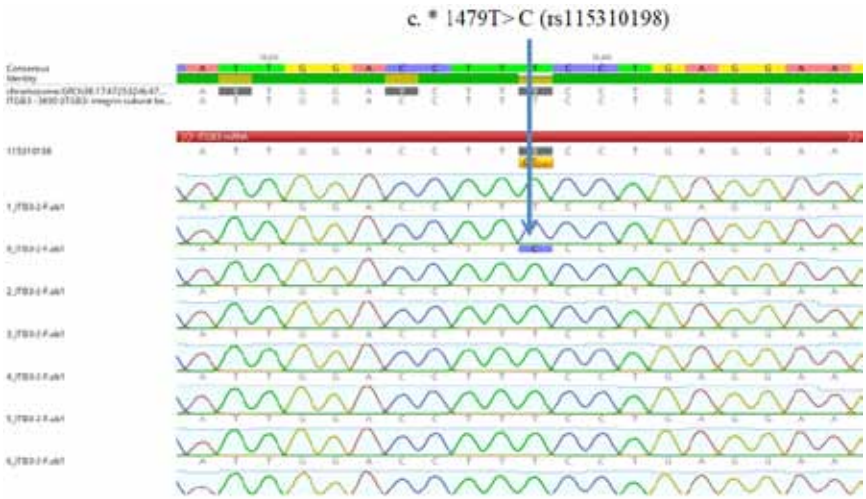

Figure 2 : The DNA direct sequencing for GT patients show the nucleotide substation T>C at position 1479 in 3UTR region for *ITGB3* gene .

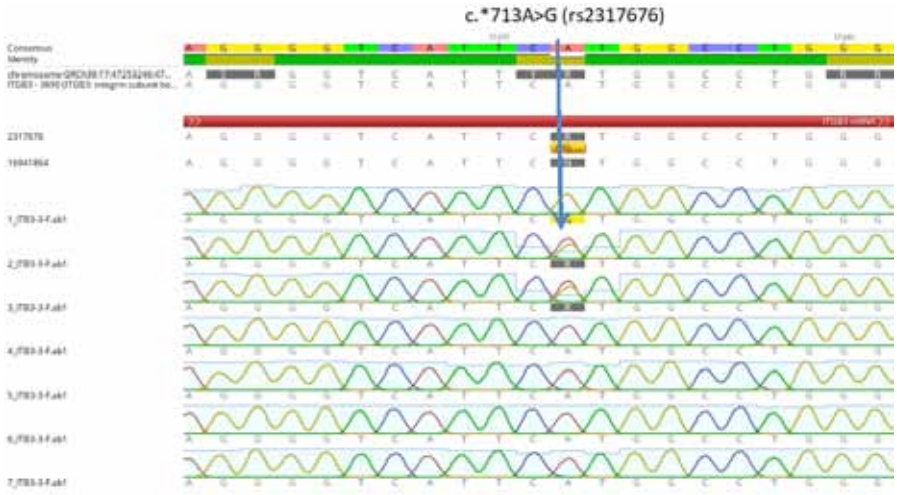

Figure 3 : The DNA direct sequencing for GT patients show the nucleotide substation A>G at position 713 in 3UTR region for *ITGB3* gene .

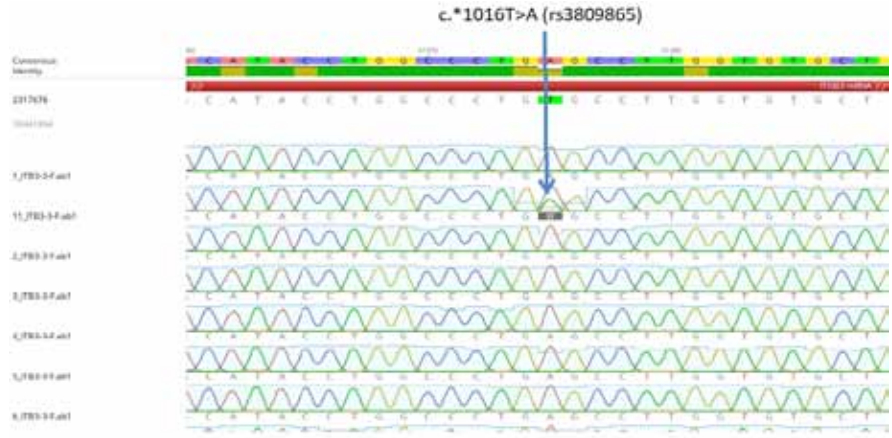

Figure 4: The DNA direct sequencing for GT patients show the nucleotide substation T>A at position 1016 in 3UTR region for *ITGB3* gene .

The SNP rs2317676 (c.*713A>G) at a place: 47310917 for chromosome (GRCh38.p12) was presented with two alleles (*A* and *G*) and three genotypes (AA, AG and GG). These genotypes showed deviation from HWE in GT patients, because there was a significant difference between the observed and expected genotype frequencies ($p \leq 0.05$),it was also noticed the genotypes frequencies (AA, AG and GG) show deviation from HWE in controls group with significant difference ($p \leq 0.05$). Comparingcontrols to GT patients revealed that genotype frequencies of AA (80.6vs. 90%), AG (6.6vs. 5%), and The third genotype (GG) 13.3vs. 0% . These genotypes were non-significant difference (P>0.05) compared between control and GT patient. it was also noticed the frequency of mutant allele (*G*) show non-significant difference ($p > 0.05$) in GT patients compared with controls (16.6 vs. 5 %; OR = 3.8; EF = 0.4; 95% C.I. = 0.70 to 20.63), while in the control group the frequency of (*A*) allele show a non- significant difference ($p > 0.05$) compared to GT patients (83.3 vs. 95%; EF 0.71; 95% C.I. 0.05 to 1.43) . In this case the (*A*) allele associated with healthy subject and non-associated with GT patients(reciprocal OR = 3.8)and considered as protective factor (Table).

The rs115310198 at position 47311683 for chromosome 17(GRCh38.p12) was presented with three genotypes (TT, TC and CC), and two alleles (*T* and *C*) .These genotypes showed deviation from HWE in GT patients, because there was a significant difference between the observed and expected genotype frequencies ($p \leq 0.001$),it was also noticed a deviation from HWE in controls treatment with non-significant difference ($p > 0.05$). Comparing controls to GT patients revealed that

genotype frequencies of TT (87.6 vs. 95 %), TC (0 vs. 5 %), and The third genotype (CC) 13.3 vs. 0% . The TT, TC, and CC genotypes were show non-significant difference(p>0.05) between healthy subject and GT patient . The CC genotype (OR= 7.5) was considered as risk factors . it was also noticed the frequency of mutant allele (*C*) show non- significant difference (p > 0.05) in GT patients compared to controls (13.3 vs. 2.5%; OR = 6; EF = 0.03; 95% C.I. = 0.65 to 55.05) that mean (*C*) allele is risk factor associated with GT patients and negatively associated of healthy, while in the control group the frequency of (*T*) allele show non-significant difference (p>0.05) compared to GT patients (86.6 vs. 97.5; OR = 0.17; EF 0.37; 95% C.I. = 0.02 to 1.53) and it (OR = 6 reciprocal) was considered as protective factor of health subject (positively associated of health and negatively associated of GT patients) (Table).

Desiccation

Glanzmann'sthrombasthenia laboratory diagnosis depends on a series of studies on platelet aggregation, molecular biology, elisa, and flow cytometry[4].

In this study, the ELISA technique was used to differentiate between Glanzmann's patients and other patients with platelet dysfunction based on a comparison with the control group.

The use of ELISA technology can identify platelet diseases by determining the amount of reaction between

the antigen and the receptor, so that it is possible to diagnose the presence of platelet dysfunction and the severity of the disease. the receptor GPIIb/IIIa on the platelets act as the target antigen. The use of ELISA technique for detection of cases in GT and also which is effective cost, easy, sensitive, and specific perform diagnosis [(4).]

c.*1016T>A (rs3809865) and c. * 1479T> C (rs115310198) are located in the 3´UTR region of the *ITGβ3* gene. The 3´UTR region regulates the expression and regulation of β3 integrin gene at the mRNA level, and interacts with miRNA (1). rs3809865 and rs115310198 may functionally affect the binding of miRNA, therefore, the protein expression level of integrin β3 subunit [(12)(13).]

c.*713A>G (rs2317676) is located in the 3´UTR region of the *ITGβ3* gene. SNP can affect the expression of integrin by affecting the stability of microRNA. (MiRNA) and gene binding, this is the mechanism proposed by rs2317676 (A/G) for the *ITGB3*miRNA binding site, which can affect the residual amount of a IIbb3 in the presence of other causal mutations, but this remains to be proven in GT[(14)].

Abstract

An Incomplete abortion is one of the complications that often occur during pregnancy, but the biomolecular mechanism is still unknown. It has proven to be an increase in apoptosis activity that is controlled by a variety of proteins, including p53 Ser 46, Bcl-2, and caspase 3, in uteroplasenta and reproductive organs. The aim of the study is to measure the level of protein p54 Ser 46, Bcl-2, and caspase 3 in abortion and normal pregnancy. A case control study conducted in 38 cases of incomplete abortion and 38 normal pregnancies as a control. The level of protein of Ser 46, Bcl-2, and caspase 3 examined by ELISA independent/Duplo. The higher level of p53 Ser 46 (> 0,09 U/mL) led to higher risks of abortion with OR 8.52; 95% CI, 2.65 to 28.6. The higher level of Bcl-2 led to higher risks of abortion with OR 3.75; 95% CI, 1.24 to 11.68. The higher level of caspase 3 (> 7 mg/mL) and p53 Ser 46 (> 0,09 U/mL) led to higher risks of abortion with OR 71.15; 95% CI, 8.74 to 578.92; with the result of series p, p, 0.001; $p < 0.008$; and $p = 0.001$. Level of protein p53 Ser 46 and caspase 3 in abortion is higher than normal pregnancies, while the Bcl-2 protein levels in abortion is lower than normal pregnancies.

Introduction

Abortion is the termination of pregnancy before 20 weeks pregnancy or fetal weighs less than 500 grams. It is still an obstetric problem that has not been uncovered[1-3]. Abortion is one of the causes of maternal and fetal mortality today. The causes of abortion have been reported are due to genetic disorders such as abnormalities of the conceptus as a result of chromosomal abnormalities [4-6]. Other causes include developmental abnormalities of the zigot, embryo of placenta, infection, endocrines disorders and immunological disorders. Abortion is also influenced by maternal age, parity, and history of recurrent abortion[2,7-10]. Abortion is a highly complex process, controlled by variety of genes, including the gene p53, cl-2, and the caspase of cysteinyl aspartate specific proteinase (caspase). All of the genes play a role in the regulation of apoptosis either in a normal or abnormal circumstance which results in pregnancy failure. The involvement of apoptosis activator can cause excessive apoptosis. The presence of excessive

apoptosis will continue with cell death characterized by caspase 3, ended with abortion [11-17].

The excessive apoptosis in syncytiotrophoblast will result in failure of pregnancy, in addition to the role of the decidua and plasenta to give support and protect embryo development. Result of human studies has not found an association between the gene p53 through the protein p53 expression on Ser 46 and Bcl-2 agains caspase 3 in the first trimester and the association with the incidence of abortion. Based on that, we were interested to investigate [17-19].

Research Method

The subjects were pregnant women with gestational age between 10-20 weeks who diagnosed with in incomplete abortion (as the case group), whereas normal pregnancy as a control group. The inclusion criteria are 10 – 20 weeks of gestational age and maternal age between 16 – 35 years. We excluded subjects with abnormal uterine; kidney disorders, heart disease, hypertension, diabetes mellitus, lung, thyroid, and other chronic diseases, malignancy; pregnant with help medication or taking hormonal drugs.

This is a comparative analytic study with case control design. The sample size was determined based on the formula to test the hypothesis by using a correlation coefficient r ($n = 36,5 \approx 37$ people per group). The research activities carried out in the Section/ SMF Obstetrics and Gynecology FKUP/RSHS, Cibabat Cimahi Hospital, dr . Slamet Garut Hospital, and Gunma University, Japan. The independent variables are levels of protein p53 Ser 46, Bcl - 2 and caspase 3; the dependent variables are an incomplete abortion and normal pregnancy; by confounding variables that maternal age, gestational age, and parity.

We examined the levels of protein p53 Ser 46, Bcl-2 and caspase 3 at the Laboratory of the Department of General Surgical Science, Graduate School of Medicine Gunma University, Maebashi, Gunma, Japan. The Shapiro-Wilk used for normality test data, the T test is used to compare two values average normal distribution of data, X2 test (Chi squared) was used to test for differences in percentage to the data presented in contingency tables, Mann-Whitney test was used to compare differences in 2 the middle value the data which are not normally distributed, Rank Spearman correlation test is used to find relationship between two numerical variables, Odd ratio: in the case-control study pointed to the ratio between the odds at-risk and non-risk groups, logistic regression aims to analyze data in multiple independent variables and nominal numeric scale, the nominal scale dichotomous dependent variable. Significance based on the value of meaningful when p≤0,05, very meaningful p≤0,01.

All of the subjects involved voluntary after receiving explanation of the advantages and disadvantages (informed consent), the subject were also free to resign at any time for any reason without causing changes in the quality of service.

Result

Characteristics of the study subjects according to maternal age, parity, and gestational age in normal pregnancy and abortion can be seen in Table 1. Range of ages between from 19 to 35 years, parity ranges from 1 to 4, while for gestational age ranged from 10 to 14 weeks.

Table: 1. Characteristics of Subjects Research by Maternal Age, Total Parity and Gestational Age in Normal Pregnancy and Abortion

Characteristics	Gestation		Significance
	Abortus (n=38)	Normal (n=38)	
Maternal age (year)			$Z_{M-W} = 1.282$ p = 0.200
< 20	2 (5.3%)	1 (2.6%)	
20–24	4 (10.5%)	5 (13.2%)	
25-29	18 (47.4%)	13 (34.2%)	
30–35	14 (36.8%)	19 (50.0%)	
$\bar{X}$ (SD)	27.6 (4.2)	28.8 (4.6)	
Median	28	29.5	
Range	19-35	19-35	

Characteristics	Gestation		Significance
	Abortus (n=38)	Normal (n=38)	
Parity			$X^2 = 0.234$ p = 0.629
1–2	26 (68.4%)	24 (63.2%)	
≥3	12 (31.6%)	14 (36.8%)	
Range	19-35	19-35	
Gestational Age			$X^2 = 0.290$ p = 0.990
10 week	9 (23.7%)	8 (21.1%)	
11 week	7 (18.4%)	6 (15.8%)	
12 week	10 (26.3%)	10 (26.3%)	
13 week	6 (15.8%)	7 (18.4%)	
14 week	6 (15.8%)	7 (18.4%)	

Explanation: The p – value is calculated based on the Chi Square test or Mann-Whitney test
Meaningful when p≤0.05, very significant if p≤0.01;
ZM – W = Mann-Whitney

Table: 2. Comparative Levels of Protein p53 Ser 46, Bcl-2 and Caspase 3 between Normal Pregnancy and Abortion

Variable	Gestation		Z_{M-W}	p-value
	Abortus (n=38)	Normal (n=38)

> 0.09	> 6.44	>7	0.889

Explanation: ^{x} calculated as logistic regression model

Discussion

The characteristics of the study subjects included were maternal age, parity, and gestational age because these characters act as a risk factor for abortion potentially confounding variables that could affect the validity of the study. Characteristics of study subjects Ser 46 levels of p53 protein, Bcl - 2 and caspase 3 compared between cases, ie an incomplete abortion and the control group, which is a normal pregnancy. To reduce the confusion, we used cases and controls with homogeneous characteristics. Abortion happens to gestational age less than 10 weeks allegedly influenced by immunological factors and chromosomes, whereas at 10 weeks gestation or more influenced by external factors, such as infections, malnutrition, trauma, or systemic disease [2, 7, 10]. In this study, only women with gestational age of 10 weeks or more are included so that it can be removed possibility immunological factors and chromosomes that can cause abortion.

It was generally agreed that the state of maternal age ≥35 years and with the increasing number of parity would be associated with an increase in the number of abortus [7, 20]. Therefore, in this study only mothers aged less than 35 years were included in the study, considering maternal age ≥35 years found an increase in the number of abortions. Based on Table 2 showed levels of Bcl - 2 in the abortion group had a mean lower than in the normal group and differ very significantly ($p < 0.01$), whereas for protein levels of p53 Ser 46 and caspase 3 in the abortion group had a mean higher compared with the normal group different highly significant ($p < 0.01$). Savion et al reported a decrease in Bcl-2 associated with apoptosis and ends with abortion in animal experiments [18]. Bcl-2 protein is an anti-apoptotic protein strong measure to prevent the cells from death and levels remain high in the outer mitochondrial membrane. Bcl-2 protein can also be used as an early detection apoptosis. Abortion in the first trimester of pregnancy is closely linked to an

increase in apoptosis in syncytiotrophoblast compared to normal pregnancy.[22] Unlike immunohistochemistry examination, in this study with ELISA examination the serum sample derived from an unknown where the apoptosis takes place. In this study, a decrease in the levels of Bcl-2 in abortion patients compared with normal pregnancy. It shows the mitochondrial pathway plays a role apoptosis in pregnancy failure induced by regulation of Bcl-2 [12, 17, 21, 22].

In this study, table 3, 4, and 5 showed increased levels of caspase 3 was very significant in abortion patients compared with normal pregnancy ($p < 0.001$). This supports the theory that the higher the levels of caspase 3 in the first trimester of pregnancy will be more at risk of pregnancy failure. Involvement proapoptosis activators can cause excessive apoptosis, followed by cell death characterized by increased levels of caspase-3, and finally continue with abortion. Increased fetal resistance to stress teratogen is an outcomes of maternal immunopotentiating associated with a decrease in the intensity of apoptosis induced teratogenic substances on fetal structure targets. These findings indicate maternal immunopotentiating effect can be produced through the modification of the expression of molecular regulation of apoptosis induced teratogenic substances. P53 expression increase significantly in pregnancies with fetal growth retardation, but did not get a reduction in the expression of Bcl - 2 meaningful, The different results shown in this study despite the increased levels of p53 Ser 46 on abortion, the result the average levels of Bcl-2 in the study subjects who experienced abortion is lower compared with normal pregnancy were significantly different [12, 16, 17, 21, 22].

The protein p53 Ser 46, Bcl-2 and caspase 3 was significantly associated with the incidence of abortion. Multivariable sequence of the protein was strongly correlated with the incidence of abortion is caspase 3, following the protein p53 Ser 46, and last Bcl-2. Caspase 3 has the strongest risk for abortion because caspase 3 serves as the main effectors in both basic apoptotic pathway, namely receptor-mediated pathway (extrinsic) and pathways mediated mitochondrial (intrinsic). Abnormal embryonic development involves several important things, namely: 1) apoptosis induced teratogenic substances can cause structural abnormalities; 2) the effect is obviously accompanied by increased expression of TNF-α and TNFR 1 in embryonic organ; 3) resistance/sensitivity of the various structures of the embryo to the substances teratogen depends on the interaction between positive regulators of apoptosis such as caspase 3, 8 and p53, while a negative regulator of apoptosis such as NF-kB and Bcl-2; 4) maternal immunopotentiating can affect the activity of molecules that cause apoptosis in the embryo as a response to adverse stimuli and modulate the sensitivity of embryos to teratogens substances. Similar results were obtained in our study, although not further investigated what factors are causing the failure of the pregnancy [12, 17, 21, 22].

Conflict of Interest: The authors reported no conflicts of interest.

Funding: This study is self-funding research.

Ethical Clearance: The study was approved by the Research Ethics Committee at the Faculty of Medicine Universitas Padjadjaran/Hasan Sadikin Hospital, Bandung, Indonesia

Abstract

Javanese ethnic Panaragan culture is very diverse. One of them is the traditional Javanese ethnic Panaragan home. The home as a shelter is expected to bring outer and inner health to its inhabitants. The concept of a healthy house can be known to the mindset of the people contained in language. The theory used is ethnolinguistics which views language tends to reflect the mindset of a society. The method is used ethnoscience by analyzing linguistic utterances in the realm of building a healthy house. As a result, there are outer and inner concepts before building construction, healthy house space and griyowingking concept that reflects a healthy home mindset for the comfort and safety of a residence which is summarized in language patterns.

Keywords: *Home, healthy, and ethnolinguistics.*

Introduction

East Java region according to the culturalist Sutarto is divided into ten cultural regions consisting of Arek Culture, Samin (SeduluSikep), Osing (Using), Pandalungan, Madura Kangean, Madura, Pulau and Madura Bawean, Jawa Mataraman, Java Panaragan. (1) From the ten cultural regions, they have distinctive characteristics, and cultural style between regions. One of the cultures of East Java in the western region that has cultural diversity is the Panaragan Javanese Ethnic Culture.

The traditional Javanese Panaragan ethnic home, has its own way of expressing a place of staying and shelter for the Panaragan community which reflects the mindset of the society regarding concepts and mythology in building a home. To building a home, the society still has confidence in the determination of a good day that takes into account aspects of the Javanese calendar calculation (petungandino) providing earth surgical offerings (ndudokris) and geographical calculation of the layout with the hope that the homes built will become safe, comfortable, and peaceful for its inhabitants.

Figure 1. Traditional Home of Ethnic Java Panaragan (Reyog Ponorogo Document Archive)

In building a Javanese ethnic Panaragan home is guided by a calculation of days (numerology) which is learned from the ancestors based on life experiences that are adjusted to the events on a daily basis based on the day character (watakdino). In other words, the Panaragan Javanese Ethnic society adheres to the science of tit

(ngelmutiten), in order to be more vigilant, cautious and careful in carrying out an action so that events that are considered not good, will not happen again in the future, avoid something that is not desirable and always get good every day from a house that is inhabited.

Daldini and Wistodiyono state that houses are not only a building for shelter and rest but according to Javanese ancestors used as a symbol of worship to Sang Hyang MahaWasesa.(2) Thus it can be understood that Javanese society has a close relationship with mindset with a belief that expresses a form of gratitude to the creator of the universe, with the hope of life in the household ark in a house always in His shade. For this reason, the Panaragan Ethnic Javanese Society before setting up a house usually determines the best day, among other good days. On that day held a celebration of thanksgiving to God through the ritual selametan by presenting the neighbors led by warok (figure of society) or kyai (traditional religious scholar) as selametan ritual leaders who are believed to have closeness to the strength believed. This activity, carried out in the hope of obtaining the safety of the Almighty.

Besides that, in building a house, avoid locations called sunduk sate (like satay) or just in front of the three way intersection (totokan). This perception is based, because of the safety factor which is of course the location of the sunduk sate is worrying if there is an accident that usually occurs due to someone's negligence in driving a vehicle. In addition, this assumption also underlies psychologically it can disrupt the peace and tranquility of the soul for residents because every day they are faced with a vehicle that seems to go to the end of the road or called a taboo so that it is not good for the health of the owner's soul because his heart is likened to every day crash (sunduki).

Abstinence (Pantangan) in building a home in the Panaragan Javanese Ethnic society, of course has a consequence that will occur if these restrictions are violated by the society. Even though this belief is increasingly fading, some people avoid it as a precaution. Therefore, in building a house, requires some consideration of certain aspects in maintaining harmony between physical and mental health. That is, the house that will be built gives comfort and tranquility in terms of physical buildings that affect the health aspects of the householder's inner, but also gives spiritual health to the residents of the home because it brings peace and tranquility to the inhabitants. This study aims to find the relationship between language and culture in Javanese Panaragan society, especially the relationship of language and mindset that reflects the view of life in the realm of building a healthy home. Thus, the hope of the purpose of this study is expected to be achieved.

Theory and Method

The theory used in this study refers to the adjusted Sapir-Whorf hypothesis, namely, that basically language tends to reflect the mindset of a society. In other words, the language tends to reflect the ethnic mindset as contained in the knowledge system. (3) This study uses an ethnoscience approach. The focus of attention is the principles of classification as expressed.(4)(5) This method is applied in an effort to find activities that apply to the Panaragan Javanese society in order to find patterns related to how to build a healthy home, ways before building healthy homes, patterns of form and architecture that reflect their world view and other empirical concepts that apply on the Javanese Panaragan society.

Results and Discussion

(a) The Concept of Ethnic Panaragan Inner Healthy Home: To create an inner healthy atmosphere, in building a house, the Javanese Panaragan ethnic society first saw the place to be used which included the location and type of land. The location that is used is safe from various possible disaster threats, such as landslides and floods that can occur naturally. These considerations are chosen carefully, so that in the future there is no unwanted thing that can harm materially and immaterially. Although every human disaster does not want, alert is the main road. The calculation of the location is an important factor because many people experience material losses in the form of assets in the event of a natural disaster or immaterial in the form of psychological psychology such as traumatic, especially if left by a loved family

Experience the history of land by the Panaragan ethnic society as one of the important elements in building a home or buying a home. Therefore, you must first know the origin and history. In building a home, the Panaragan ethnic society after determining the location and history is free from the problems, then the next step is usually by holding calculate the day (pitungdino) with the use of the Javanese calendar. The person appointed is usually called pujonggo or a friend who is believed to be smart and has the accuracy in determining the

best day between good days or called the exspresion of linguistic nagadino.

After the process of determining the day is good, the next step is the process of surgical earth (ndudukris) in modern terms now known as the laying of the first stone by holding selametan inviting relatives and tonggoteparo to run the hajadan and prayer together to make a circular formation in the place of the house to be built like a pager with the purpose of the home to be built is to avoid danger through prayer pagers in a circle sitting cross-legged in the middle of uborampe in the form of chicken, banana, jenangsengkolo, money and eggs. This concept then becomes a life guideline for some Javanese people in building a home that is very concerned about the harmony of inner and outer, because the house is used for a long period of the time, so keeping the house into a comfortable residence is a must even though in the form of a home that is not too luxurious, but it's more important to live happily and always bring blessings.

b) The concept of Physic Panaragan Ethnic Healthy Home: The home is a physical structure consisting of room, yard and surrounding area that is used as a place of residence and means of family formation.[6]While the understanding of houses according to WHO (World Health Organziation) is a physical structure or building for shelter, where the environment is useful for physical and spiritual health and social conditions both for family and individual health.[7] The function of the house is as a place to let go of fatigue, socializing, fostering a sense of kinship between family members, sheltering and storing valuables, and as a symbol of social status.[8]

A healthy home is a physical structure of the building as a shelter or shelter and a place to rest so that it grows a perfect life both physically, spiritually and socially culture and free from illness or weakness (Disability). In general, the house is said to be healthy if it meets the following criteria.[7]

Physical aspects of the building for the Panaragan ethnic society have several elements of a standard healthy home. A healthy home must have several important components. Among other things are the components or structure of the house, sanitation and healthy behavior of the occupants, which are then elaborated in the form of more indicators, namely components, structure and condition of the ceiling, walls, floors, windows, bedrooms, living room windows, ventilation, holes kitchen smoke, lighting, cages, and yard utilization. From these elements, above the construction structure of the shape and space of the Javanese Panaragan ethnic house is generally the same as the other traditional Javanese traditional houses.

According to Yunitathe main home is at least composed of three masses of this building, surrounded by a wide yard.[9] The yard consists of latarngarep, on the front, latarmburi, in the back and latarwetan and latarkulon on the side. Ngarep or front yard is an average of 10 m to 15 meters of roadside, serves to dry the harvest. The background (latarmburi) is large to occupy sumur, jedhingblandhong (bathroom), kakus (WC), and pawuhan (trash bins) tegalan and stables. side yard of the latarwetan is on the east side, while the latarkulon is on the west side, serves for moor or gardens and places blumbang or fish pond

c. The Variety of Ornaments: Art of Architecture and symbolic meaning: The shape of the roof of a traditional Javanese Panaragan ethnic home has an interesting variety of decoration and architecture from a certain point of view. The variety, among others, is found in the upper part of wuwungan in the Panaraganjoglo house. The position of wuwungan which has an angle and aesthetic value is a symbol of the service of the crown of the king. The ornament, sometimes resembling a tiger's ear, symbolizes the strength and dignity of a house.

The decorative model is in the form of decorations with various shapes and motifs. Soko is a foundation that serves to support the roof. Soko on the upper end usually has ornate carvings in the form of lists and carvings and at the bottom there is a umpaktampak that supports the mighty. This Soko is often in the belief of the ancients given a rope bond as a tight binding symbol of a single entity, if someone who comes then feels comfortable, like there is a brotherhood among guests who present with the home owner as a symbol of brotherly ties by visiting each other. Tumpangsari is an ornament as a form of aesthetic creation by placing tumpangsari towards the outer midhangan and overlapping towards the midhangan. According to Susilo The number of tumpangsari levels varies.[10] The number of levels is no provision, depending on the availability of materials. which means showing the level of ability of homeowners. The use of overlapping is not mandatory, but when using overlapping the number of levels must be odd, three levels or five levels or not at all.

The difference between tumpang and tumpangsari in addition to its position, as well as its structural aspects. Tumpangsari supports the roof, its function is related to the function of the other elements, so it cannot be replaced at any time. Tumpang functions only as a cover of the bottom roof cavity, do not support the structural system. Then tumpang can be replaced, added or reduced the level. Even carving decorations can also be given, of course the other elements of the carving must be adjusted.

d. The Healthy Space: Expression of forms of air ventilation and lighting functions: Ventilation is a process of circulating air that enters the room naturally. Air ventilation serves to keep oxygen levels intact and affect the level of humidity in a room Inside the traditional Panaragan ethnic home there are usually two windows consisting of one window on the west side and one window on the east side. This ventilation, has a philosophy of air entering from one side can come out on the other side so that the air in the room will continue to experience change and freshness for the occupants in it. In addition this ventilation also functions as lighting in the morning and evening so that at that time there is no artificial lighting as it is now, the room will remain bright even though there are no lights because the sun in the morning and evening can enter the room. This concept indirectly has implications for the health of the residents of the house because in addition to maintaining the circulation of air freshness in helping breathing can also avoid moisture which can lead to susceptibility to disease seeds.[11] This simple concept influences the pattern of action in the expression of embodiment of a healthy home according to the Panaragan ethnic community. Therefore, usually on the side of the house there are emperkiwo and empertengen. Emperkiwo as the road to pasucen is a place to clean yourself or the bathroom and toilet As for empertengen as the road to the pawon and storing agricultural products such as grain, casava, and corn

Conclusion

The concept of a healthy home according to the Panaragan Javanese community is that there are two standards that become unity, namely the concept of inner health and outer health. The concept of inner health is reflected in the expression of language in determining the day before building a house by determining the best day by performing a petungandino tradition at the time of the earth in the hope that the house to be built brings blessing During this process, the Ponorogo society also held a salvation as a form of gratitude to God by holding a prayer together inviting the brothers, relatives and neighbors to join together to win the divine blessing of God. As for outwardly the concept of healthy ethnic panoramic house is reflected in the safe construction, ornamental variety as a form of symbolization that reflects hope and prayer, healthy space with adequate ventilation and lighting, clean floors, and sanitation facilities that are protected from pollution and landfills which is adequate as a form of behavior to maintain the health of its inhabitants. The concept that is actualized becomes an integral unity to realize a healthy home avoiding various kinds of hazards, and diseases that can be caused by lack of concern for health factors.

Strengthen the Authoritative Function of the Regional Representative Councils in Legislation

I Gusti Bagus Suryawan

Lecturer at Warmadewa University, Indonesia

Abstract

The existence of the Regional Representative Council (DPD) in the constitutional structure in Indonesia can strengthen the parliamentary system which in turn can strengthen democracy. The substance of regional representation in the DPD is the accommodation of regional interests which is guaranteed constitutionally and elaborated with laws and regulations. This study is to analyze the reconstruction of DPD's regulatory functions in the fields of legislation, supervision and consideration. The regulation of DPD functions in the field of legislation, supervision, must be reconstructed in the 1945 Constitution of the Republic of Indonesia with the formulation of "legislative and oversight power exercised by the DPR and DPD" which is to replace the regulation of the DPD function in the legislative field which is limited to filing bills and participating in discussions at level I, but do not have authority for the decision making stage. Also the DPD does not have a supervisory function, because the DPD cannot follow up on the results of supervision and the follow-up to the results of supervision is a political and legal determination by the DPR (House of Representatives).

Keywords: *Legal Reconstruction, Function, Regional Representative Council, Legislation.*

Introduction

The existence of the Regional Representative Council (DPD) in the constitutional structure in Indonesia can strengthen the parliamentary system which in turn can strengthen democracy. The constitutional basis of the DPD's power is regulated in Article 22 D of the 1945 Constitution of the Republic of Indonesia. The constitutional foundation as the basis for the formation of the DPD can be found in Article 22 C and Article 22 of the 1945 Constitution of the Republic of Indonesia. The authority of the DPD as regulated in the provisions of Article 22 D paragraph (1) and paragraph (1) 2) The 1945 Constitution of the Republic of Indonesia regulates that the DPD can submit to the House of Representatives a draft law relating to regional autonomy, central and regional relations, the formation and expansion and merging of regions, management of natural resources and other economic resources, as well as those relating to central and regional financial balance. In addition, the DPD also discussed the draft law relating to regional autonomy; central and regional relations; formation, expansion, and merging of regions; management of natural resources and other economic resources, as well as central and regional financial balance; and giving consideration to the House of Representatives on the draft budget law for state income and expenditure and the draft law relating to tax, education and religion.

As a translation of Article 22 C and Article 22 D of the 1945 Constitution relating to the DPD, is regulated in Law Number 27 of 2009 as last amended through Law Number 17 of 2014 concerning the People's Consultative Assembly, the People's Representative Council, the Regional Representative Council and the Regional House of Representatives (hereinafter abbreviated as MD3 Law). The substance of regional representation in the DPD is the accommodation of regional interests which is guaranteed constitutionally and elaborated with laws and regulations. Legislation as a legal product is the basis for making state administrative decisions; be the basis for the formation of legislation; become the basis of legal relations between citizens and the

resolution of social problems. In this context, legislation as a legal product becomes a very important tool in the administration of state life.[1]

Even though the DPD was born, it was not yet fully present.[2] Meaning, DPD can be considered between 'there' and 'none'. The DPD is 'there' because of its relatively strong legitimacy and its members are elected directly through the multi-district district election system. The DPD is also 'absent', because the strength of the legitimacy of the election results does not go hand in hand with its relatively minimal authority, especially when compared to the authority of the DPR. This study formulates a problem that will become a central point regarding the reconstruction of the DPD's regulatory functions in the fields of legislation.

Research Method

This type of research is sociological normative legal research that examines and examines statutory provisions relating to the function and authority of the DPD. The study includes 3 layers of legal science namely legal philosophy (right philosophy), legal theory (right theory) and legal dogmatics (right dogmatics). This study uses several approaches, namely the historical approach (historical approach), conceptual approach (conceptual approach), statutory approach, comparative approach, and sociological approach.

Position of the Regional Representative Council in the Constitution and State Administration: The existence of the DPD is expected to strengthen the parliamentary system which in turn can strengthen democracy. The constitutional basis of the DPD's power is regulated in Article 22 D of the 1945 Constitution of the Republic of Indonesia. Furthermore, the function and authority of the DPD is regulated in the MD3 Law and P3 Law. According to MD3 Law, the DPD can submit a bill proposal to the DPR. If a bill is approved or approved with amendments, the bill will become a bill proposed by the DPR. Furthermore, the DPD proposal bill which has been adopted as the DPR proposal bill, the DPR leadership will ask the DPD leadership to appoint a tool that will discuss the bill in the DPR. Discussions on a bill in the DPR are conducted in two stages of discussion. First-level talks are held in commission meetings, joint commission meetings, Baleg meetings, Banggar meetings, or special committee meetings. Meanwhile, the second level talks were held in a plenary meeting which was a forum for decision making. Of the two levels of discussion, the DPD RI can only take part in the level I discussion. It is also only done in the form of a mini-opinion submission delivered at the end of the level-1 discussion. The illegality of the first level of discussion so that the discussion of a bill can continue at the second level.

Based on the results of interviews with Syamsul Bachrie (Monday August 15 2016) related to the absence of DPD's participation in decision making in the sense of participating in a joint agreement between the DPR and the President after the Constitutional Court's Decision, it will cause the law to be legally flawed. That the judicial law is flawed when the DPD does not participate in the decision making process of a bill under discussion.

In the legislation process, this imbalance is increasingly seen in Law P3 and MD3 Law. Article 20 paragraph (1) of Law P3 regulates: "Preparation of National Legislation Program shall be carried out by the DPR and the Government". The norm of Article 20 paragraph (1) is not in line with the purpose of Article 22 D of the 1945 Constitution of the Republic of Indonesia that "the DPD can submit to the DPR a draft law relating to regional autonomy". Likewise the provisions of Article 20 Paragraph (3) of Law P3 "Preparation of Prolegnas within the DPR as referred to in paragraph (2) is carried out by considering proposals from factions, commissions, members of the DPR, DPD, and/or the public.

This arrangement seems to indicate that the function of the DPD to submit a bill is distorted as if it were the authority of the factions and commissions as the DPR's completeness instruments. The DPD is only authorized to propose a bill to be submitted to the DPR, then the proposal for the DPD bill will depend on the DPR's follow-up actions in the parliament. In other words, the DPD is a sub-ordinate of the DPR or only a supplementary organ of the DPR in the two-chamber parliamentary system.

The regulation of DPD functions in Law P3 as explained above, is not in accordance with the principle of rating norms. Law as a translation of norms in the Constitution, regulates norms that are not in accordance with what is ordered by the Constitution. Which is why the DPD does not carry out its constitutionality function optimally. Likewise, looking at the provisions of Article 65 paragraph (3) of Law P3, the participation of the DPD in the discussion of the Draft Bill is carried out only at

the level 1 discussion. Article 150 paragraph (3) of the MD3 Law also excludes the DPD from being involved in the DIM discussion as the DPR and the Government, whereas the submission and discussion DIM is precisely the core of the discussion of the bill and determine the legal politics of a bill.

Kelsen's teachings describe the process of forming a system that originates from a set of norms, including the inclusion of a norm into a particular system so that the construction of Kelsen's teachings also explains the validity of a norm. The existence of a norm is formed as a result of the formation of a norm is to regulate the procedure for someone's behavior towards other people or the environment. A norm applies because it has conductability or because it has validity (validity/ geltrung).

Basic principles for understanding thinking if there are more than one person in the same space and time. Because the legal validity of Hans Kelsen who must especially understand the keywords against the validity of norms according to him; "The reason for the validity of a norm is always a norm, not a fact".[3] Here Kelsen has given a basic principle regarding the norm's sequence. A norm cannot be based on a factual event because a norm can only be pursued with fellow norms to its basic norms where there are no norms forming on it. As continued on the second basic principle; "a norm of validity of which cannot be derived from a superior norm we call a" basic "norm" (norms whose validity cannot be obtained from other higher norms, we refer to as "basic norms"). Kelsen absolutely states that norms must be tested with norms, norm hierarchies if pulled up until no more norms are found so the last norm is referred to as the basic norm.

Gaffar (2004) stated that the formation of the DPD is inseparable from two things. First, there is a demand for democratization to fill members of representative institutions so that they always include the voters.[4] There was a demand that the representation system be a two-room system. The DPD and the House of Representatives are described similarly to the representative system as in the United States which consists of the Senate as the state representative (DPD), and the House of Represents as the representative of the whole people (the DPR). In the United States, these two elements of representation are called the Congress. Article 1 paragraph (1) of the United States Constitution of 1787 states: All legislative powers here in granted shall be vested in a Congress of the United States, which shall consist of a Senate and House of Representatives.[5]

One consequence of the idea of the two chambers is that names are needed for the representative body that reflects these two elements of representation. In the Netherlands the representative body is the Staten Generaal which consists of de Eerste Kamer (representative from the region) and de Tweede Kamer (representative of all the people). In Britain, the Parliamentary representative body consisting of the House of Lords (representative of the group) and the House of Commons (representative of the whole people).

The name of a two-room representative body in Indonesia in accordance with the above construction, was named MPR. As a consequence of the use of the MPR as the name of the two-room system, the MPR should not be an office environment that has its own authority environment. The authority of the MPR is inherent in the authority of the DPR and DPD. In the United States Constitution which is determined is the authority of the Congress and its implementation is carried out by its representative chambers.

The function of parliament is as representative and deliberative assemblies. Parliament in a modern state not only represents the will of the people, but is also a deliberate place, especially in the field of legislation to oversee regional interests in government administration and government policy. Legislative power is power that reflects the sovereignty of the people, to regulate life together. There are three important things that must be regulated by the people's representatives through parliament, namely arrangements that can reduce the rights and freedoms of citizens, which can burden the assets of citizens; and regarding expenses by state administrators.

Authoritative Function of the Regional Representative Council in Legislation: There are 4 forms of legislative function activities in the formation of laws, namely law making initiatives, discussion of bills, approval of the ratification of bills and granting approval of binding or ratification of international treaties or agreements and other binding legal documents.

In the formation of laws based on the 1945 Constitution of the Republic of Indonesia, the House of Representatives participates in all stages of the implementation of the legislative function, whereas the DPD is only entitled to propose, participate in discussion, and also give consideration to certain bills.

Because it is not complete in following the four forms of activity, it can be interpreted that the DPD does not have a legislative function.

Every legislator is obliged to understand the applicable laws and regulations. Proper mastery of statutory law will contribute highly relevant to the law-making profession.[6] Inaccuracy in mastering the applicable laws and regulations can be a cause of flawed legal rules that are formed both formally and materially. In addition, it is known that legislation has a very strategic function for the administration of the state. There are two functions of legislation, namely the protection function and the restriction function.[7] The function of protection is the function of legislation to provide guarantees for the protection of the relationship of rights and obligations in a shared life. In addition, legislation also plays a role to limit the use of rights and obligations themselves so as not to harm the rights of others.[8]

A very strategic part in the stages of drafting legislation is to fill in the formulation of legislation with the choice of norms or guidelines for appropriate and proportional behavior. The drafting of the legislation must be able to distinguish the notion of rules from norms. Bruggink gives a firmer term, the rules and rules of law.[9] It shows that the regulation of the functions of the DPD in the 1945 Constitution of the Republic of Indonesia with the MD3 Law and P3 Law shows the asynchronous norm. This has implications for the accommodation of regional interests through the field of legislation that cannot be fought for optimally.[10]

Conclusion

The regulation of DPD functions in the field of legislation, supervision, must be reconstructed in the 1945 Constitution of the Republic of Indonesia with the formulation of "legislative and oversight power exercised by the DPR and DPD" which is to replace the regulation of the DPD function in the legislative field which is limited to filing bills and participating in discussions at level I, but do not have authority for the decision making stage. Also the DPD does not have a supervisory function, because the DPD cannot follow up on the results of supervision and the follow-up to the results of supervision is a political and legal determination by the DPR.

Abstract

The purpose of this study is to investigate the association between knowledge and attitude on quality of life among diabetic patients type 2 in Palestine.

Method: A cross-sectional quantitative descriptive study that contains a sample of 120 diabetic patients were selected from Nablus hospitals and outpatient clinics to assess the level of knowledge and attitudes toward self-care and health-related quality of life.

Results: The mean score of Michigan Diabetic Knowledge Test was 8.04±2.48 and this consider a moderate level. Of 120 diabetic patients, 27.5% had poor knowledge; 65.5% had moderate knowledge, and only 6.6 % had good knowledge. The mean for attitude score of all respondents was 125.4±10.57 and this consider a positive attitude. There was a significant positive association between knowledge, attitude with HRQol (P=0.00). The mean for HRQoL score was 0.72 and it represented a moderate level of quality of life. Conclusion: Level of knowledge scores and HRQol were moderate and attitude toward the disease was positive in type 2 diabetic patients in Palestine, and there was a strong association between knowledge, attitude on HRQoL.

Keywords: *Type 2 diabetes mellitus, knowledge, attitudes, health-related quality of life.*

Introduction

Diabetes mellitus (DM) is a common chronic disease of global epidemic proportions and considered as a metabolic disorder that may be caused by disturbances of the body essential ingredients such as carbohydrate, fats, proteins metabolism that result from a defect of insulin secretion, its function or both[1-2]. The World Health Organization reported that the prevalence of diabetes was 171 million; this number is predicted to reach 300 million by 2030[1]. Findings. Nowadays International Diabetes Federation offers that each year 5,000,000 deaths are because of diabetes, which is more than the HIV/AIDS, tuberculosis, and malaria combined[3-4]. Knowledge and attitudes toward DM is the first step to be taken to formulate prevention programs for diabetes patients [5], and the impact of education among diabetic patients will be more beneficial and more effective[6].Health-related quality of life (HRQoL) has also been recognized as an essential health outcome, it is represented as the ultimate goal among various health outcomes. It is characterized as patient-perceived physical, emotional, and social well-being[7]. Understanding the factors that associated with poor quality of life (QOL) has a benefit in terms of promoting the physical and psychosocial burden associated with DM, eventually minimize costs, morbidity, and mortality [8].

Knowledge and HRQoL alone is not enough for diabetic patients to affect changes in their lifestyle, the attitude is influencing factor that affected in the relationship between knowledge and lifestyle changes. However, there are limited studies in worldwide and no studies in Palestine discussing knowledge among diabetic patients and the effects of diabetic patients' knowledge and attitudes on HRQoL. So, in this study aimed to assess present knowledge, attitudes, and quality of life among diabetic patients type 2 in Palestine.

Materials and Method

Design: A cross-sectional quantitative descriptive design was used to identify relationship between the knowledge and attitude on quality of life among diabetic patients type 2 in Palestine, using structured interview with 120 diabetics 2 patients.

Settings: Sample recruited from, hospitals and outpatients' units of Nablus, Palestine.

Sample and Population: a sample of 120 Patients aged 18 years and above, with a confirmed diagnosis of DM-II and willing to participate were included in this study. While patients who were pregnant, documented psychological problems, mental illness and who have diabetic complications renal failure, retinopathy, and diabetic foot were excluded.

Data collection Procedures: Data collection started after ensuring ethical approval from the Institutional Review Board (IRB) Committee of the College of Medicine, An- Najah University. Arabic versions of the tools were used adopting the who guideline in translation.

Instrumentation: The data collected using the following instruments

1. Demographic data that include gender, age, marital status, type of treatment, HbgA1C, and duration of the disease.
2. Michigan diabetic knowledge test (MDKT) to asses level of knowledge, it consists of 14 multiple-choice items. Each one of the patients was asked to choose only one answer for each question, the correct answer scored one point, and the false answer scored zero. The range of the knowledge test was from 0 to 14 where the higher score of the test, the higher level of knowledge about diabetes and the zero represents the low level of knowledge about diabetes. The score of <7 considered as poor knowledge, 7-11 considered moderate knowledge about the disease, 12-14 considered to be a good score for knowledge.
1. Diabetic self-care profile was used from the University of Michigan. It used to assess the attitude of diabetic patients,the questionnaire contains from 33 questions. All items were scored: strongly disagree,disagree, neutralagree, agree, and strongly agree. The range of score from 33 to 165 the higher the score the positive the attitude toward diabetes care. This scale divided to 5 subscales: Need for special training to provide diabetes care, Seriousness of type 2 diabetes, Value of tight glucose control, Psychosocial impact of diabetes and attitude toward patient autonomy.
2. EuroQol five-dimensional (EQ-5D) to asses HRQOL, it consistsfrom two parts. The first part talks about self-reporting their health status, it talks about 5 dimensions: mobility, self care, usual activities, pain\discomfort, anxiety\depression, Each dimension contains from five levels of severity, (no problems,,slight problems,moderate problems, severe problems, unable problems). The range of the each dimension was formed from 1 to 5, where the five is the highest score of the item known as the highest level of quality of life and the 1 represents the low level of quality of life. The second part that was conducted contain a visual analog scale (VAS), with endpoint were 0 represent bad health status and 100 represent excellent health status, that was conducted to assess and record each of the subjects about their perception on her or his quality of life.

Findings:

Demographic Characteristics: 140 patients approached and 120 questionnaires completed, with response rate of 85%. the mean age (SD) was (57.83± 12.69) years; Mean HbA1c was (8.41±1.55) and the mean duration of diabetes was (10.24± 8.28) years, 52.5% were female, 65.8% (n = 79) of the participants were married. About 60.8% (n =73) had average income, About 36.7% (n = 44) had a High school level of education.

Table 1: Characteristic of the patients (N = 120)

Variable	Frequency	Percentages
Gender

11-15	14	11.7%
16-20	9	7.5%
More than 20	13	10.8%

Knowledge of DM: The mean score of the MDKT was (8.04±2.48), indicating that, the patients had a moderate level of knowledge about diabetes, good knowledge was most apparent in response to the questions related to the problems that usually not associated with diabetes (80.8% were correct) and the effect of exercise on blood glucose (80.8% were correct), Poor knowledge was most apparent in response to the questions related to food that should not be used when blood glucose was low(68.3% were incorrect). Questions regarding the effect of unsweetened fruit juice on blood sugar (62.5% were incorrect), which foods contained the fattest also tended to be answered incorrectly (60% were incorrect).

Differences in knowledge and attitude related to socio-demographic characteristics: According to knowledge among female and male patients, it wasn't significant (p=0.5) also the attitude score wasn't significant (p=0.081), The age wasn't significant for both attitude (p=0.11) and knowledge score (p=0.081), According to marital status, it was only significant for the knowledge score (p=0.005), divorced females slightly more knowledgeable toward DM (8.44±2.4), according to attitude score it wasn't significant.According to economic status, it was significant both for knowledge (p=0.007) and attitude score (p=0.001), patients who had moderate-income has better knowledge(8.54±2.39) and better attitude (128±9.5). According to the education level it was significant for the knowledge score (p=0.01) the patient who has a master's degree is more knowledgeable about DM for the score of(11±0.00). But the attitude score wasn't significant, for those who receive a different type of treatment, it show only significance for attitude score (p=0.014), and the highest score was for those who receive diet treatment (126.2±11.6), the knowledge score wasn't significant (p=0.107). According to the result of the last HbA1c, it was significant for the knowledge score p= (0.028) and attitude score (p=0.02) the highest result was for a patient with HbA1c 7-8(128+-8.40), According to the duration of DM it was significant for the attitude score with (p=0.02), those who have DM between 6-10 years, have a better attitude(129.9±7.5) but it wasn't significant for knowledge score.

Differences in wellness scale related to socio-demographic characteristics: According to gender, there was no significance for the wellness score (EQ-VAS) (p=0.88) and the (EQ-5D)(p=0.8). The marital status showed that there was significance in Qol, single Patients had higher scores than married (20±5.6 vs. 19.7±5.8) for (EQ-5D). According to the economic status, it shows significance for both EQ-VAS (P=0.000) and EQ-5D (p=0.00), the patient who has moderate income present the highest score for wellness (75.44±17.6) for EQ-VAS. The education level shows significance for the EQ-VAS (p=0.000) and EQ-5D (p=0.000), for those patients who have a master and bachelor's degree, they have the highest QOL (24±1) for (EQ-5D). According to

the duration time of DM, it show significant for the EQ-VAS (p=0.012) and the EQ-5D(p=0.006), for those who had DM duration of 5 years or less, show the highest wellness score (73±22.4) for(EQ-VAS). For 5-

Discussion

In this study the mean score of knowledge was (8.04±2.48), while using the Michigan diabetic knowledge test (MDKT), that was an indication of moderate knowledge. The results are is consisted with previous report[1, 11-15]. Also, 60% of the patients were incorrect regarding the food that contain most fat and this consist with indicating that patients with DM-II had poor knowledge about the effect of unsweetened fruit juice on blood sugar and the food that contain most fat. In this study, we found that there is a relationship between educational level and knowledge score in which those participants with master degree got the highest score(11+-00) and this consist with these studies[16-20]. It is obvious from previous studies that type 2 diabetic patients have lower scores of HRQoL than rest of populations of similar age. In this study, the mean of EQ-5D score in type 2 diabetic patients was 0.72, which is considered a moderate score, and this consistent with other studies that reported mean EQ-5D scores as 0.74, 0.69, 0.70, 0.71 and 0.70[21-23].

Conclusion

In this study, level of knowledge was a moderate, attitude was positive, and the level of HRQOL was also moderate level. Patients who receive diet management had high attitude score, high score of knowledge and attitude reported in 7-8 HbA1c. It is recommended to conduct a longitudinal study that address consequences of poor knowledge and low quality of life.

Education as Predictor of Low Birth Weight among Female Worker in Indonesia

Ina Kusrini[1], Noviati Fuada[1], Sri Supadmi[1], Agung Dwi Laksono[2]

[1]Researcher, Unit of Health Research and Development Magelang, Indonesia Ministry of Health, Central Java, Indonesia, [2]Researcher, Center of Research and Development of Humanities and Health Management, Indonesia Ministry of Health, Jakarta, Indonesia

Abstract

Female workers are a vulnerable group in Indonesia because in addition to working to help their husbands earn a living, they also still have to be responsible for domestic affairs. This study aimed to analyze the effect of the level of education on the incidence of LBW in female workers in Indonesia. The analysis uses the 2017 Indonesian Demographic and Health Survey data. Stratification and multistage random sampling method get 18,061 female workers as respondents. The final stage was done using binary logistic regression. The results found that there was no difference between primary education female workers and no education female workers at the risk of giving birth to LBW babies. Secondary education female workers have a 0.561 times chance compared to no education female workers to give birth to LBW babies. Meanwhile, higher education female workers have a possibility of 0.414 times compared to no education female workers to give birth to LBW babies. Apart from the education level, the results of the analysis also found two other variables as predictors of LBW among female workers, namely wealth status and ANCvisits. It was concluded that the education level is a predictor of LBW among female workers in Indonesia. The higher the education level, the lower the possibility of female workers to have LBW babies in Indonesia.

Keywords: *Low birth weight, female worker, education,maternal health, nutrition.*

Introduction

Female workers are a group that is prone to various health-related risks[1]. In addition to exposure in the workplace, women who are also of childbearing age need optimal health conditions because it is a key element of intergenerational health[2,3]. Adequacy of nutrition for women, whether they are still in the status of young women, pre-pregnant adults, and even more so during pregnancy, are factors that directly contribute to the nutritional status of the children they will be born with[4]. A study conducted in several developing countries states that three socio-economic factors can explain the problem of child malnutrition, namely women's social status, sanitation, and urbanization. The positive influence of children's nutritional status is related to the role of women in decision-making and gender equality in society, in addition to caring for children and providing nutrition directly from mother to fetus[5].

For this reason, the health of female workers is an important factor in achieving the goals of global health development. Globally, the female labor force participation rate is quite high (% of female population ages 15+), in 2019 it is estimated at 47.14%. Meanwhile in Indonesia, the percentage of female workers is greater, namely 53%in 2019 it is estimated at 47.14%. Meanwhile in Indonesia, the percentage of female workers is greater, namely 53%[6]. This means that most women in Indonesia are female workers, both in the formal and informal sectors. In general, women workers work in three sectors, namely education, health, and

social workers[7]. The average profile of housewives in Indonesia is also a worker, although not as the main support for family economic activities. They work in agriculture, services, and trade with the status of helping their husbands or families.

Among the risk factors for women in the workplace were revealed by previous studies. A high workload and a lower wage than men are experienced by female workers on average. On average, women dedicate 3.2 times more working hours per day than men to unpaid work[8]. The International Labor Organization states that 76.2% of women do unpaid care work. Besides, exposure to environmental hazards, stress, and nutritional insufficiency. Various risks experienced by women have an impact on public health if they cannot be controlled optimally[7]. Previous studies revealed that 81% of children to working mothers have a higher risk of neonatal death when compared to children born to non-working mothers[9]. Female workers who experience malnutrition are at risk of producing malnourished babies. One of the indicators of malnutrition is the low birth weight (LBW), a previous study stated the relationship between female workers and the occurrence of LBW[10,11].

LBW is currently the main cause of child mortality and mortality. Every year nearly 1.1 million babies die from complications of preterm birth. LBW is not only a major predictor of prenatal mortality and morbidity but also increases the risk of slower cognitive development, non-communicable diseases such as diabetes and cardiovascular disease later in life[7].Several studies suggest that LBW is associated with poverty and education indicators[12,13].LBW had the consequence that they had to spend the first few days or weeks of life in the NICU. This is to ensure the baby's life is guaranteed with an artificial uterus. The risks of complications that can be suffered by LBW babies are the health consequences of LBW infants, thermoregulation, hypoglycemia, fluid and electrolyte imbalance, nutrition, hyperbilirubinemia, chronic lung disease, patent ductus arteritis, infections, necrotizing enterocolitis, intraventricular hemorrhage, apnea of prematurity, anemia, hearing and adult health problems[14]. Based on the background description, this study aims to analyze the effect of the level of education on the incidence of LBW in female workers in Indonesia.

Materials and Method

This research was employed with secondary data from the 2017 Indonesian Demographic Data Survey (IDHS). The analysis unit was female workers aged 15-49 years old who had given birth in the last 5 years. The 2017 IDHS sampling method was done by stratification and multistage random sampling so that there were 18,061 female workers as respondents.

LBW is a birth weight of fewer than 2,500 grams (or 5.5 pounds). LBW is determined regardless of gestational age. Birth weight is the first birth weight of a newborn measured after birth[15]. The education level is the last certificate the respondent has. Other independent variables analyzed in this study were age group, marital status, wealth status, ANC visits, and smoking behavior.

The final stage for determining the education level as a predictor of LBW was done using binary logistic regression because of the nature of the dependent variable. All statistical analyzes were carried out using SPSS 22 software.

Results and Discussion

Table 1 shows descriptive statistics of the education level of female workers in Indonesia. It can be seen that all categories of education level are dominated by female workers who give birth to LBW babies, except for female workers who have higher education. Based on the age group, all education level categories were dominated by the 35-39 age group, except for female workers who had higher education, which was dominated by the 30-34 age group.

Based on marital status, all education level categories are dominated by female workers who are married/living with partners. Meanwhile, based on wealth status, all categories of education level were dominated by the poorest female workers, except for female workers who had higher education, which was dominated by the richest. Based on the ANC visits, all education level categories were dominated by female workers who made complete ANC visits (≥ 4 times) during pregnancy. Finally, based on smoking behavior, all education level categories are dominated by female worker smokers.

Table 2 shows the results of the binary logistic regression of LBW among female workers in Indonesia. It was found that there was no difference between primary education female workers and no education female workers at the risk of giving birth to LBW babies. Secondary education female workers are 0.561 times

more likely than no education female workers to give birth to LBW babies (OR 0.561; 95% CI 0.370-0.850). Meanwhile, higher education female workers have a 0.414 times chance compared to no education female workers to give birth to LBW babies (OR 0.414; 95% CI 0.265-0.645). This information shows that the higher the education level, the lower the possibility of female workers to produce LBW babies in Indonesia.

A high level of education is one of the outputs of women's empowerment. Better education has an impact on maternal nutrition and reduces the incidence of LBW[16,17]. Several previous studies have informed that a good level of education is a major predictor of performance in the health sector[18,19]. On the other hand, poor education is an obstacle for the health sector to produce quality output[20,21].

Apart from the education level, the analysis also found two other variables as predictors of LBW among female workers in Indonesia. First, wealth status. The richer female worker has a 0.708 times chance compared to the poorest female worker to give birth to LBW babies (OR 0.708; 95% CI 0.568-0.882). The richest female worker has a probability of 0.722 times compared to the poorest female worker to give birth to LBW babies (OR 0.722; 95% CI 0.572-0.912). Wealth status as a predictor of LBW because it relates to food availability in the household. The poorer a family, the lower the food availability[22]. Several studies provide consistent findings. Some of them were carried out in India, Ethiopia, Bangladesh, and Pakistan[23–26].

The second, ANC visits. Female workers who made complete ANC visits (≥ 4 times) during their pregnancy were 0.603 times more likely than female workers who made incomplete ANC visits (<4 times) to deliver LBW babies (OR 0.603; 95% CI 0.497-0.730). The results of this analysis inform that carrying out complete ANC visits is a protective factor for LBW among female workers in Indonesia.

Conducting ANC visits as recommended by the Ministry of Health at least 4 times during pregnancy will monitor the health of pregnant women properly[27]. If there is a risk of pregnancy, for example, the mother is underweight, interventions can be immediately carried out to provide the best delivery output for the mother and the baby[28].

Conclusions

Based on the research results, it can be concluded that the education level is a predictor of LBW among female workers in Indonesia. The higher the education level, the lower the possibility of female workers to have LBW babies in Indonesia.

Dental Care Interventions as Efforts to Reduce PUFA Index and Improve Nutritional Status in Children aged 9-12 Years in Orphanages

Indrayati Fadjeri[1], Rahaju Budiarti[1], Tedi Purnama[1]

[1]*Assistant Professor, Department of Dental Health, Health Polytechnic of Jakarta I, Indonesia*

Abstract

The main problem in the child's oral cavity to date is dental caries. Untreated dental caries could cause difficulty eating and sleeping, experience pain, and need continuous care, so that it impacts on poor quality of life, and health problems arise one of which is the condition of the child's nutritional status. This research aims at effectiveness Dental Care Interventions as Efforts to Reduce PUFA Index and Improve Nutritional Status in Children aged 9-12 Years in Orphanages. Method: this study used a quasy experiment with a pretest and posttest with control group design. This research was conducted at the Mizan Amanah Orphanage in Cinere District, Depok City. Independent variable: Dental care intervention and dependent variable: PUPA index and children's nutritional status. Data tested using Wilcoxon/paired sample t-test and independent t-test/mann whitney test and linear regression. Results: Dental care interventions were effective in reducing PUPA index ($p < 0.001$) and were effective in improving the status of children aged 9-12 years ($p < 0.011$). Conclusion: effective dental care interventions as efforts to reduce PUPA index and nutritional status of children aged 9-12 years in orphanages

Keywords: *Dental care interventions, PUFA Index, nutritional status.*

Introduction

The main problem in the child's oral cavity to date is dental caries. This was proven by Nelwan research (2015) in Yataama Al Firdausi orphanage Semarang, showing the prevalence of dental caries by 69.7% while the results of the 2013 Basic Health Research reported the prevalence of Indonesian population with oral and dental health problems of 25.9%. So it can mean the orphanage children have higher caries.[2-4]In some countries the prevalence of dental caries has decreased in the last twenty-five years, but in developing countries, including Indonesia, the disease is still a major problem in adults and especially in children.[5]

Corresponding Author:
Tedi Purnama
Department of Dental Health, Health Polytechnic of Jakarta I, Wijaya Kusuma Raya Street, No. 47, Jakarta, Indonesia
e-mail: tedypurnama23@yahoo.com

A study in Delhi India of 520 children aged 9-12 years published in 2011 showed a caries prevalence of 52.3%, the mean def-t for children aged 9 years was 2.17 and age 12 years was 0.27; while the average DMF-t of 9-year-old children is 1.1 and the age of 12 years is 0.8. Other studies in Peru showed the mean DMF-T of 12-year-old children was 3.92 with a caries prevalence of 83.8%.[6-7]

Caries is an infectious disease that results from bacterial interactions. Dental caries occurs due to the demineralization process of bacterial interactions on the tooth surface. Bacteria are acidic so that within a certain period of time, acids will damage tooth enamel and cause cavities. The etiological factors for caries are plaque microorganisms, diet and time.[8]

Untreated dental caries can cause difficulty eating and sleeping, experience pain, and need continuous care, thus impacting on poor quality of life, and health problems arise. One of them is the condition of the nutritional status of children. Children who experience dental caries will experience pain in the hole, so that it

will reduce consumption of food. Children who reduce food consumption in the long term, will have an impact on the nutritional status of children.[9]

According Rohmawati (2016) dental caries is a disease that can interfere with the nutritional conditions of children so that it can cause nutritional problems. Dental caries is a disease that can interfere with the nutritional condition of children so that it can cause nutritional problems, with nutritional status but can also be related to the severity of dental caries.[10]

Some problems that arise in untreated caries such as pulpitis, ulceration, fistula, abscess and pulp necrosis. The index used to calculate the severity of untreated dental caries is known as the PUFA index. In permanent teeth, this index is written using capital letters (PUFA) while milk teeth are written using lowercase letters (pufa).[11, 12]

Siregar research (2019) showed the severity of untreated dental caries that had caused an open pulp (P/p) of 1.54; traumatic ulceration around soft tissue (U/u) on average by 0.06; there is no severity of untreated dental caries that has caused fistulas (F/f); and has caused inflammation or abscess (A/a) of 0.07 on average. Another study by Pratiwi (2013) also proved the overall prevalence of caries at the age of 6 years by 62% with the highest component of caries in deciduous teeth and 8 permanent teeth had caries with pulp involvement. For the age of 9 years 65.8% with permanent dental caries 10% and children aged 12 years the highest caries prevalence in permanent teeth, which is 25.3%.[5, 11]

Efforts are made to overcome the problem of dental and oral diseases by approaching health workers and dentists in the form of dental and oral health services in the form of activities with promotive, preventive, curative approaches, which are carried out in an integrated, comprehensive, and sustainable manner. Dental care interventions to reduce PUPA index are dental fillings and extractions. It is expected that the pain caused by dental caries can be overcome and the function of chewing can function optimally so that the intake of nutrients is good and can affect the nutritional status of children.[3]

Based on background above author interested in conducting research under the title "Dental Care Interventions as an Effort to Reduce PUFA Index and Improve Nutritional Status in Children Aged 9-12 Years in Orphanages"

Method

The method used in this research is quasy experiment with pre and post-test with control group design. This research was conducted at Amanah Mizan Orphanage in Cinere District, Depok City. The data collection was carried out in August - September 2019. The research sample was taken using a purposive sampling technique, consisting of 62 respondents consisting of an intervention group of 32 respondents and a control of 32 respondents. The independent variables in this study were dental care interventions and the dependent variables were PUPA index and children's nutritional status. Research data using ratio scale, statistical tests using Wilcoxon/paired sample t-test and independent t-test/Mann Whitney test and linear regression. The research stages are as follows:

1. Respondents were selected according to criteria
2. Samples were divided into 2 groups, the intervention group was given dental care measures and the control group was only given mouth rinses.
3. Before examining the oral cavity we provide counseling on how to maintain healthy teeth and what are the effects if cavities are not treated.
4. The next step is to conduct a pre-test in the form of examination of PUFA index and nutritional status in the form of body mass index measurement.
5. Then the research intervention was carried out, in the intervention group the form of treatment performed was tooth extraction and dental fillings using mashed garlic and covered with temporary fillings. Whereas the control group gargled with warm salt solution.
6. After 30 days, a post-test was conducted to examine the PUFA index and nutritional status in the form of a body mass index measurement.

Result

Table 1. Frequency distribution of respondent characteristics

Variable	Intervention		Control	
	N	%	N	%
Gender				
Men	15	46.9	17	53.1
Women	17	53.1	15	46.9
Age (Years)				
9-10	15	46.9	14	43.8
11-12	17	53.1	18	56.3

Table 1 shows the respondents in this study consisted of 34 men (53.12%) and 30 women (46.88%). The intervention group consisted of 15 men (46.9%) and 17 women (53.1%) while the control group consisted of 17 men (53.1%) and 15 women (46.9%). The age variable found that children aged 9-10 years amounted to 15 people in the intervention group and 14 people in the control group. While respondents aged 11-12 years there were 17 people in the intervention group and 18 people in the control group.

Table 2. Average PUPA index values and Nutrition Status

No	Variable	Intervention		Control	
		Pre-test	Post-test	Pre-test	Post-test
1	**PUPA index**				
	Mean	1.44	0.47	1.28	1.09
	SD	1,076	089	1,746	1,532
	Min-Max	0 - 5	0 - 4	0 - 7	0 - 6
2	Nutritional status				
	Mean	17.55	17.77	16.14	16.36
	SD	2,363	2,295	2,462	2,250
	Min-Max	13.2 - 22.4	13.5 - 22.8	9.8 - 21.1	10 - 20.8

Table 2 shows, the average PUFA index in the intervention group was 1.44 before treatment and in the control group was 1.28, which means that there were an average of 2 cavities that were not treated. After dental treatment in the form of dental fillings and extractions, the average PUFA was found to decrease to 0.47 in the intervention group while in the control group it was 1.09. This table also shows changes in nutritional status in the intervention group on average 17.55 before treatment and there is an increase in nutritional status to an average of 17.77. Whereas in the control group the average nutritional status was 16.14 and after treatment it was 16.36.

Table 3. Test the effectiveness of the PUPA index and nutritional status before and after dental care interventions

Group		PUPA Index *		Nutritional status**	
		Mean + SD	P-value	Mean + SD	P-value
Intervention	Pre-test	1.44 + 1,076	0.001	17.55 + 2,363	0.011
	Post-test	0.47 + 0.879		17.77 + 2,295	
Control	Pre-test	1.28 + 1.746	0.064	16.14 +2.462	0.168
	Post-test	1.09 + 1.532		16.36 +2.250	

* Wilcoxon, ** Paired Test Samples

The results of effectiveness test data before and after dental treatment showed PUPA index p-value of the intervention group was 0.003 ($p < 0.05$) and the control group's p-value was 0.064 ($p > 0.05$) while the nutritional status showed the intervention group's p-value was 0.011 ($p < 0.05$) and the p-value of the control group was 0.168 ($p > 0.05$) meaning that the administration of dental care interventions effectively increased the PUPA index of nutritional status in children of the Mizan Amanah orphanage.

Table 4. Different tests of PUPA index and Nutrition Status in the intervention and control groups

Group		PUPA Index *		Nutritional status**	
		Mean + SD	P-value	Mean + SD	P-value
Intervention	Pre-test	0.47 + 0.879	0.050	17.77 + 2,295	0.015
	Post-test				
Control	Pre-test	1.09 + 1.532		16.36 + 2,250	
	Post-test				

* Mann-Whitney, ** Independent Sample Test

The results of the PUPA index difference test showed the p-value between the intervention group and the control group was 0.050 (p <0.05), meaning that the provision of dental care interventions was more effective in increasing the PUPA index than the control group. While the nutritional status shows the p-value between the intervention and control groups is 0.015 (p> 0.05) meaning that the provision of dental care interventions is more effective in improving nutritional status compared to the control group.

Table 5. Dental care most influential on nutritional status

Variable	B	P value	R Square	C	Annova P-value
Dental filling	1,083	0.145	0.177	19.28	0.05
Tooth extraction	1,502	0.025			

* Linear regression

Based on table 5, it can be seen that the constant value is 19.28 with a dental filling coefficient of 1.083 meaning that a 1% dental filling intervention will increase nutritional status by 1,083. The tooth extraction coefficient value of 1.502 means that the 1% tooth extraction intervention will increase the nutritional status by 1,502. The results of the analysis show the results of R2 (R Square) of 0.177 or (17.7%), meaning that dental filling and tooth extraction interventions have a 17.7% effect on improving nutritional status. The analysis showed that the value of p = 0.05 means that the influence of dental filling intervention and tooth extraction has an increase in nutritional status.

Discussion

Nutrition is food intake related to the body's need for food. Adequate nutrition includes quality, quantity, and the body's ability to use it carefully to meet the body's metabolic needs. With many cases of cavities that are not treated immediately will cause pain and discomfort when eating which can result in decreased appetite that will affect body mass index.[13, 14]

The results of the test of the effectiveness of data before and after being given dental care showed a value of p <0.05. This situation shows that by decreasing cases of untreated caries (PUFA index) by treating dental problems can improve the nutritional status of children. This situation is in line with research conducted by Rohmawati (2016), which states that there is a significant relationship between the caries index that is not treated with nutritional status. This can happen because if a tooth is damaged or disrupted it will interfere with the function of mastication and will tend to choose soft foods so that it will reduce the intake of nutrients that will affect the child's weight.[10, 13]

The results of the analysis of the types of treatments that are most effective for obtaining nutritional status show that both dental care interventions, either tooth extraction or dental fillings can reduce the pain that may

arise when they consume food so that there is no more interference when teeth are used for masticatory function, this condition allows increased food intake which can improve nutritional status. In accordance with secondary factors that affect nutritional status,

namely the presence of impaired digestive function of food such as tooth decay/disease, the digestive apparatus that causes food cannot be digested properly, so that incoming nutrients cannot be absorbed properly resulting in insufficient body needs.[10, 15]

Judging from the type of treatment, dental filling interventions provide changes in nutritional status better when compared to treatment of extraction. In the case of filling most of the cavities are already on the pulp, causing pain when used for chewing and after filling the pain is reduced so that it can perform mastication function is better and there is an increase in nutritional status. Patches made to close cavities using garlic ingredients to reduce pain and were quite effective for a while, because it can also improve the nutritional status of children.[16] Nevertheless dental care must be continued for permanent fillings.

Conclusion

Based on the results of the study, it can be concluded that:

1. Dental care interventions were proven to be significantly ($p < 0.001$) effective in increasing the PUPA index of children in the Mizan Amanah orphanage.
2. Dental care interventions were shown to be significantly ($p < 0.001$) effective in improving the nutritional status of Mizan Amanah orphanages.
3. Dental care interventions in the form of dental fillings and extractions have a 17.7% effect on improving nutritional status.

Psychological and Personality Development Supports to the Prisoners in Correctional Institution in Indonesia

Irma Cahyaningtyas[1], Nur Rochaeti[1]

[1]Lecturer at Faculty of Law, Universitas Diponegoro, Semarang, Indonesia

Abstract

The correctional institution is a place for treatment the prisoners. The current condition, the responsibility for treatment prisoners lies with the state, carried out by one institution without assistance from other institutions, namely the Correctional Institution. The problems in this paper are first, what is the current form of treatment for prisoners in Correctional Institution; second, how to reconstruct the form of treatment for prisoners in Correctional Institutions in the future. This paper uses an empirical juridical research method using the socio-legal approach. The results in this paper are first; the treatment aimed at current prisoners is personality treatment and independence treatment. In practice, both of these treatments found obstacles in the form of inadequate facilities and infrastructure and overcapacity of the Correctional Institution conditions, which resulted in no ideal coaching; second; based on this, it is necessary to reconstruct treatment of prisoners in the Correctional Institution. Reconstruction was carried out by developing a form of community-based correction and the existence of cooperation from the private sector in the form of partnerships. If this is realized, the purpose of the treatment process can be achieved, and the prisoner, after finished treatment, can return to the community properly.

Keywords: *Legal reconstruction,psychological treatment, correctional institution.*

Introduction

Penitentiary is a place to foster prisoners. Penitentiary is a criminal system that has moved far away from the philosophy of retaliation, detention, and resocialization. In other words, punishment is not intended to make suffering as a form of retaliation, it is not intended to deter suffering, nor does it assume the convict is someone who lacks socialization. Penalization is also in line with the social reintegration philosophy which assumes crime is a conflict that occurs between the convicted person and the community so that punishment is intended to restore conflict or reunite the convicted person with his community[1].

Article 1 point 2 of Law No.12 of 1995 concerning Corrections states that the correctional system is an arrangement regarding the direction and boundaries and method of fostering prisoners based on Pancasila which is carried out in an integrated manner between the supervisor, the fostered, and the community to improve the quality of the assisted citizens. Correctional facilities in order to realize mistakes, improve themselves, and not repeat criminal acts so that they can be accepted back by the community, can actively play a role in development, and can live naturally as good and responsible citizens.

The working of the penitentiary system requires an approach. This approach can be done through a coaching stage process. In connection with the development of prisoners, in undergoing the prison process, prisoners are given guidance which is essentially to return the prisoner to a good, confident, independent, active and productive society. Thus, these coaching activities must pay attention to various aspects of the life of prisoners in order to have independence and strong self-confidence[2].

Guidance and guidance for inmates is carried out by special functional officers, namely Correctional Officers or supervisors. Thus, the implementation of the correctional requires professionalism of human resources who will understand well the objectives of the correctional and how to achieve these goals, and to avoid inhuman treatments. In fact, at this time, the development process is the responsibility of the state which is carried out by the correctional institutions only. Of course, this situation is not comparable to the situation in prisons that are over capacity[3]. One of the countermeasures is the presence of the role of other parties in the process of coaching prisoners. This role is not only in the form of collaboration with related government agencies and social institutions to support effectiveness but also a role to participate in the process of coaching prisoners.

Several papers that have previously discussed about the development of prisoners, including a paper that discusses the development of prisoners in a correctional perspective which in practice leads to the development of each individual prisoner[4]. Another paper discusses several criminal acts committed by inmates, including murder, theft, robbery, sexual violence, and illegal arms sales[5]. Another paper examines efforts to reduce the density of prisoners in correctional institutions, where one of them is to provide jobs to inmates and reward inmates for the success of the work[6]. The next paper discusses the fulfillment of health for prisoners where prisoners are often affected by mental disorders and infectious diseases. Therefore, meeting health needs needs to be well accommodated[7]. In this paper, we will discuss the form of training for prisoners in correctional institutions and efforts to reconstruct in relation to the development of prisoners in the future.

Research Method

This paper uses the empirical juridical research method, which examines the applicable legal provisions and what happens in reality in society or research is carried out on the actual situation that occurs in society, with the intention of finding the facts that are used as research data which are then analyzed to identify problems which in turn lead to problem solving[8]. The research specification in this paper is descriptive analytical[9]. So that it can describe the conditions of coaching for prisoners in correctional institutions and the description is analyzed with the help of theories and opinions from the results of other papers in relation to an effort to reconstruct the development of prisoners.

The approach used in this paper is socio-legal. Socio-legal study is a study of law using the approach of legal science and social sciences[10]. The soci-legal approach is used in this paper to explain the efforts to reconstruct the development of prisoners by emphasizing legal and non-legal aspects so that ideal prison development is created.

Social and Psychic Rehabilitation of Prisoners: According to Article 1 paragraph 3 of Law no. 12 of 1995 concerning Corrections, which states that penitentiary is a place to carry out the development of prisoners. The prison system in Indonesia is actually a substitute for the prison system which is a colonial legacy. In 1964 in Indonesia, a correctional system emerged which was the idea of Sahardjo, in relation to the Treatment of Offenders. The conception of correctionalization is not merely formulating the objectives of imprisonment, but is a system of guidance, a method in Treatment of Offenders which is multilateral oriented by focusing on the potentials that exist in the individual concerned, as well as those in the midst of society as a whole. The correctional system has a very important meaning, because it changes the direction of the aim of imprisonment, which is a way to guide and foster prisoners[11]. Several aspects that need to be emphasized in the coaching process include:[12]

a. **Social rehabilitation:** In the coaching process, there must be social guidance in the form of counseling, direction and personality development, so that they will live as human beings with personality and faith.

b. **Vocational rehabilitation:** In the coaching process there must be an emphasis on effective and effective skills. This is because inmates after completing their sentence can return to work in society. Therefore, it requires preparation in order to live in a new social environment. If you do not have this provision, there is the possibility of relapse.

c. **Education rehabilitation:** In the coaching process there must be practical education. This is because there may be prisoners who are illiterate and drop out of school.

d. **Medical rehabilitation:** In the coaching process, it is necessary to have health/mental medication to treat various background problems of prisoners, for example due to stress, frustration, and others.

The process of coaching prisoners is currently regulated in the Decree of the Minister of Justice of the Republic of Indonesia Number: M.02-PK.04.10 of 1990

concerning the Guidance Pattern of Prisoners. Coaching is divided into 2 areas, namely personality development and independence development.

First, personality development includes, among others: development of religious awareness; development of the nation and state; development of intellectual abilities (intelligence); development of legal awareness; and development of integrating with the community.

Second, development of independence is provided through programs, namelyskills to support independent businesses; skills to support small industrial enterprises; the skills are developed according to the talents of each prisoner; and skills to support industrial businesses or agricultural (plantation) activities using intermediate technology or high technology

Hence, the guidance given to prisoners must be an integral part of the correctional system. Correctional that is seen as a system must have an ultimate goal that must be achieved so that in its implementation it requires assistance from parties other than the state which is responsible for the functioning of the guidance process.

Psychological and Personality Development Supports for Prisoners: Penal reform is part of the criminal law policy/politics (penal policy). According to Barda Nawawi Arief, Criminal law reform essentially contains meaning, an effort to reorient and reform criminal law in accordance with the central values of socio-political, socio-philosophical and socio-cultural Indonesian society which underlie social policies, criminal policies and law enforcement policies in Indonesia[13]. In essence, criminal law reform must be pursued with a policy-oriented approach and at the same time a value-oriented approach[14].

Efforts to reconstruct the development of prisoners cannot be separated from the problem of value, because crime is used as a means of achieving correctional objectives, namely in the implementation of criminal sanctions it does not mean that the punishment imposed on prisoners must be in accordance with human values but must also be able to raise awareness of prisoners of value, human values and social values in society.

Reconstruction specifically regarding the formation of prisoners must be carried out. The reconstruction is expected to realize an effective, efficient and effective process of guiding prisoners. This is quite reasonable, given the ideal purpose of the prison system. However, in practice there are many obstacles that exist in the development of prisoners at this time so that it can affect the granting of prisoners' rights.

The reconstruction of the development of prisoners in prisons in the future can be carried out by developing ideas so that punishment leads to de-institutionalization or non-institutionalization of punishment in the form of community-based correction and assistance from the private sector in the form of partnerships. Developments towards deinstitutionalization, such as social work, probation and diversion and restorative justice have been practiced in a number of countries for humanitarian considerations as well as to avoid the bad effects of imprisonment for children, women who still have child dependents, and first offender crime categories light. According to this article, philosophically, this development does not contradict the basic idea of correctionalism. Partnerships are needed to help from the aspects of coaching, financing, partnerships as well as supporting the formulation of a more effective strategy. Therefore, partnerships are needed both with other government agencies and elements of society.

The current situation, the training of prisoners carried out in the Correctional Institutions is too bureaucratic, so this creates an impression of being unfriendly and inhuman. The presence of a third party, in this case the private sector, is expected to be able to solve the problems of coaching prisoners. This paper describes the form of private participation in the prisoner development program, which can include providing skilled professionals such as psychologists, pedagogists, social workers; providing trainers and work equipment to support training for prisoners, including in the provision of raw materials and the throwing of products produced by prisoners; after the convicts have finished serving their sentences, the private sector is expected to distribute the labor of ex-convicts who are deemed eligible; contributing funds to finance the basic needs of inmates while serving their sentences; providing reports on the development of prisoners to the government.

According to this paper, the presence of the private sector in the process of coaching prisoners can be seen from two sides. The first side, if the private sector helps ease the duties of correctional institutions in fostering prisoners, it is hoped that it can focus on making inmates as citizens of society who are aware of illegal acts to become skilled in certain jobs and obey the law after they are in society; the second side, there are advantages

for the government, namely constraints, both funds and facilities and infrastructure can be overcome so that the correctional institution can be a place to foster inmates without retaliation; benefits for the private sector, namely developing company work programs, increasing the workforce for the development of the company's business progress, as the moral responsibility of Pancasilian Indonesian citizens.

It is hoped that the presence of the private sector in the process of coaching prisoners can make the Penitentiary a productive institution in preparing prisoners to return to society as working people who comply with the law[15]. In the end, the coaching process in the future can achieve the goal of the correctional system, namely to restore the life relationship between prisoners and the community.

Conclusions and Recommendations

The form of guidance given to prisoners in correctional institutions today is personality development and independence development. In practice, this guidance encountered obstacles, among others, conditions in prisons that were over capacity, limited facilities and infrastructure so that they could affect the provision of guidance to prisoners to which the prisoners were entitled. On the basis of constraints in the process of guiding prisoners, it is necessary to reconstruct the development of prisoners in correctional institutions in the future, namely by developing ideas so that punishment leads to de-institutionalization or non-institutionalization of punishment in the form of community based correction and partnership assistance from the private sector.

The suggestions put forward in this paper are as soon as possible the development program in reconstruction through various forms of guidance so that the private sector can help directly and increase the existence of the open prison. If this is realized, the role of the correctional institution can be helped in the process of developing a more humane and can produce productive prisoners so that when they have finished undergoing guidance, the prisoners can return to the community properly.

Abstract

The development of endowment land in Indonesia is very rapid which is directly proportional to the problems that occur regarding endowment. The resolution of this endowment dispute is based on the charity law, carried out by deliberation and mediation. In some cases, the mediation conducted was not following the existing mediation rules so that eventually the resolution of the endowment dispute became ineffective. It is important to study the problem of the resolution of endowment disputes through mediation from the perspective of the theory of legal effectiveness. This study aims to understand and analyze the problematic of endowment dispute resolution through mediation from the perspective of the theory of legal effectiveness in Central Java. The research method used is socio-legal research, with an empirical juridical approach and includes qualitative research. The results of this study are the settlement of endowment disputes through mediation outside the court according to the theory of legal effectiveness, not yet effective, because there are no formal legal rules. It is necessary to make regulations for the implementation of non-litigation mediation, to provide practical guidance for the implementation of mediation in the community.

Keywords: *Charity, Mediation, Dispute Revolution.*

Introduction

The endowment is developed or empowered by the community[1]. Land Endowment is always associated with public interests and economic value. This is what often causes problems that cannot be resolved internally, thus becoming a dispute. Objects that are used as land endowment disputes, usually associated with the legality status, management, and changes in the function and use of land endowment assets including buildings on it, which are adjusted to the needs of the community in utilizing endowment property. The parties to the dispute can occur between the community and *nadzir* (endowment manager), *waqif* (people with endowment) with *nadzir*, and *nadzir* with the heirs[2]. Factors causing the appearance of endowment disputes, among others; there is a misunderstanding about the understanding of endowment between *nadzir*, *waqif* and *waqif* heirs, there is a conflict of interest between nadzir and *waqif* heirs, the economic value of land prices is higher so that *waqif* heirs sometimes try to seize it, there is no charity land certificate, there is a conflict between religious law and *waqif* and state law regarding the legality of endowment land, *nadzir* defaults (breaking promises and irresponsibility)[3].

The resolution of endowment dispute has been explained in Article 62 of the Endowment Law No. 41/2004, that is, through deliberations to reach consensus, if it cannot be resolved, then it can be resolved through mediation, if mediation is not successful, then use arbitration or through the Religious Courts. According to Article 49 of Law No. 3/2006 explains that the Religious Courts has the competence to resolve endowment disputes submitted by the disputing parties. This study may be a fairly original study in presenting and examining aspects of endowment and actual problems in the context

of resolution by involving the religious community and arbitration and ADR. Although this relates to the field of business law, very few previous studies have reviewed ADR in this endowment issue[4,5,6,7,8,9]. This study aims to understand and analyze the problematic of endowment dispute resolution through mediation in the perspective of the theory of legal effectiveness in Central Java. In addition, also to find out the practice of the implementation of mediation in society and its legal problems. The benefit is that it can be used as an effort to develop legal settlement of endowment disputes through effective and optimal mediation in the community.

Resolution of Endowment Disputes: Research conducted by[10] explains that the resolution of endowment disputes in the coastal communities of Central Java, uses two pathways, namely the non-litigation route, such as; deliberation (23%) and mediation (60.8%), and litigation path in the Religious Courts (16.2%). According to these data shows that the majority of the people of the coastal regions of Central Java use non-litigation in the resolution of endowment disputes. This is because; faster process, lower cost, informal and final nature, confidentiality guaranteed, can maintain good relations, there is freedom of choice of third parties, certain face-to-face implementation, easier to make improvements, the parties can arrange procedures for dispute resolution. It can be understood that mediation outside the judiciary is the most widely used way of resolving endowment disputes by the parties to the dispute. However, after being criticized, it turned out that mediation was carried out by the parties to the dispute, many of which did not comply with the correct mediation rules, for example; the mediator acts as the party that resolves the problem, the mediator does not know the main tasks and functions so that it is not optimal in resolving disputes, and the parties are not given the opportunity to express their opinions. Thus, this study shows that the implementation of mediation in the resolution of endowment disputes has not been effective.

Research conducted by[11] about the Effectiveness of Mediation in the Settlement of Endowment Disputes (Case Study of the Endowment Land of the Baitul Qudus Mosque on Gebanganom Genuk Sari Semarang Central Java) explains that the effectiveness of mediation depends on the type of endowment dispute, the motivation of the parties to form the Baitul Qudus Mosque Endowment Case on Gebanganom Genuk Sari Semarang Central Java), agreement in dispute resolution, relating to basic/ ideological values, the ability of mediators to assist in the resolution of disputes, and the availability of funds[11]. Furthermore, the research shows that the implementation of mediation in the resolution of endowment disputes in the above case has not been effective, because the mediators are not sincere in helping the parties resolve endowment disputes and there is no awareness of the parties in having a good commitment to resolving endowment disputes.

The effectiveness of the resolution of endowment land disputes through mediation is an attempt to explain whether the rules of mediation law can apply or be implemented by the community in the resolution of endowment disputes. If the rules of mediation law can be carried out by the community in the settlement of endowment disputes, then the law is effective. In this study, what is used as a benchmark for the effectiveness of mediation in the resolution of endowment disputes are five factors as stated by[14] in the theory of legal effectiveness. Five factors that influence the effectiveness of law in society are; statutory regulations (formal juridical), law enforcement (institutional), facilities or facilities for law enforcement (human resources), society (degree of community compliance with law), legal culture (customary law that applies in society). By using the theory of legal effectiveness is used as a benchmark for the implementation of the effectiveness of mediation in the resolution of endowment disputes in Central Java society, it is revealed that factors of statutory regulations, which means rules in written form (legal formal). Rules for the resolution of endowment disputes through mediation have been explained in Article 62 Paragraph (2) of Law No. 41 of 2004 concerning Endowment, ie if the resolution of an endowment dispute cannot be resolved by deliberation, then it can be resolved through mediation. Mediation is a dispute resolution mechanism that cannot be resolved internally by parties, thus requiring other parties to resolve it[15]. Law no. 30 of 1999 concerning Arbitration and ADR are often used by parties in dispute resolution in general, but for the resolution of endowment disputes it still needs to be tested, whether the law can be used as a guideline or not, given the act of endowment has characteristics.[16] The characteristics of endowment acts are the responsibility of endowment property is intended for the community and endowment property must not be lost, damaged, but preserved for the benefit of eternity. If there is a change in objectives and benefits, it must be licensed by PPAIW and BWI as an institution responsible for endowment acts in Indonesia.

Research Method

This is a field research, its object in the Central Java region, which took samples in the cities of Semarang, Demak, Kendal and Klaten. This type of research includes socio-legal research, because it analyzes the problem of implementing procedures for the resolution of endowment disputes through mediation in the community and legal problems, so that its effectiveness can be known. This research is a qualitative research which aims to develop theoretical concepts based on data and research sources. The approach method uses empirical juridical. Juridical means research that seeks to examine matters concerning the legal basis of the legislation used, namely Law No. 41/2004 Regarding Endowment, Gor. Reg. No. 42/2006 concerning Regulations for Implementing Endowment. Empirical is research on the application of legal rules for the resolution of endowment disputes in the community, legal relations with the community. The research data needed is primary and secondary data. Primary data come from interviews with endowment service agencies in the community, namely; PPAIW (3 people), District BWI (4 people), Provincial BWI (2 people), and Religious Court judges (2 people). Secondary data obtained through literature study and documentation, secondary data includes primary, secondary and tertiary legal materials. This study uses a case study analysis that occurred in the research object area, drawing conclusions using the inductive method and the data was analyzed descriptively and analytically.

Research Result

The results showed that the resolution of endowment disputes through mediation really helped the parties in realizing a peace agreement, because mediation has several advantages, namely; there is no coercion for the parties to the dispute, instead they are protected and directed so that the dispute is quickly resolved, saves time and money, is flexible and does not seem formal/ rigid, confidential is guaranteed, and creates good relations after the dispute.

However, in the practice of resolving endowment disputes, mediation has legal issues that disrupt the existence of endowment law enforcement. Legal problems/problems in the resolution of the endowment dispute in Central Java. Mediation of endowment disputes using the rule of law as contained in Article 62 of the Endowment Law No. 41/2004. However, the mediation rules in the Endowment Law only explain globally/generally, do not explain in detail about the technical rules of mediation. Rules for mediation through justice/litigation have been explained in PERMA No. 2/2008 jo PERMA No. 1/2016, but the legal rules for the resolution of endowment disputes through non-litigation mediation have no legal rules. So far, the state has non-litigation dispute resolution rules, namely Law no. 30/1999 concerning Arbitration and ADR (Alternative Dispute Resolution). Article 1 (10) of this Law explains that the settlement of disputes through non-litigation channels is carried out by means of consultation, negotiation, mediation, conciliation, or expert judgment. However, this Act does not specifically mention clauses in the settlement of endowment disputes. Though endowments have their own characteristics, such as; endowment property is eternal must not be lost, the use of endowment property for social purposes, endowments of worship and social value. Thus Law No. 30/1999 cannot be applied in the resolution of endowment disputes. Meanwhile, the community has its own pattern in the resolution of endowment disputes based on Islamic law. Islamic law explains that the resolution of endowment disputes is carried out through deliberations towards peace, mediation and judicial judges[12,13]. The pattern used comes from the practice of Islamic scholars (in the organization of PPAIW) in the resolution of endowment disputes. However, the rules of Islamic law above are still global in nature, not yet explaining the detailed rules, so far there are no written rules established by state institutions, so the rules used are based on local customs that do not conflict with Islamic law. This is what makes the rules for the resolution of endowment disputes through mediation, do not yet have the legal force to protect the parties to the dispute.

In the settlement of endowment disputes, the mediator is usually PPAIW, because PPAIW is seen by the public as an expert in endowment law. If there is an endowment dispute, the task is to resolve the endowment dispute, so that the endowment dispute can be resolved fairly and the endowment property can be saved and the endowment law can be upheld in the community. So, the law in force in society is the law that lives in society. The role of the mediator in mediation is very important, because the success of the resolution of endowment disputes through mediation is very dependent on the mediator. Therefore, the mediator must understand the main tasks and functions so that they are professional so that they can direct the parties to a win-win solution. However, in practice what happens in the community

shows that, the mediator is chosen by the parties because it has close social, religious, kinship relations, and is not based on professionalism. This is what causes problems in mediation, because the mediator does not yet know and understand his position, what must be done and how to manage endowment dispute problems so that they can be quickly resolved.

Legal issues for the resolution of endowment disputes, namely; Article 62 of the Endowment Law only explains globally/generally about the procedure for the resolution of endowment disputes through mediation. Mediation that is carried out in the court already has a rule of law namely PERMA No. 1/2006. However, mediation that is carried out outside the court/non-litigation, there is no legal rule regarding practical instructions, so there is no legal certainty. In addition, the dispute resolution rules contained in Law No. 30/1999 concerning Arbitration and ADR, there are no clauses regarding endowment actions. This is what makes the Act cannot be applied in the resolution of endowment disputes in the community. During this time the community uses a living law derived from Islamic law obeyed by its adherents. However, Islamic law still explains globally it has not been detailed.

Conclusions and Suggestions

The resolution of endowment disputes through mediation outside the court according to the theory of legal effectiveness has not been effective, because there are no formal legal rules. Although Article 62 Paragraph (2) of the Endowment Law has explained the procedures for the resolution of endowment disputes, but there are no facilities or facilities in the law enforcement for the resolution of endowment disputes, both physical facilities, human resources and their supporters, such as good organization, adequate equipment and legal culture in the community. Based on the conclusions above, it is very urgent if the government makes regulations on the implementation of non-litigation mediation, to provide practical guidance on the implementation of mediation in the community. In addition, it also sets policies in facilitating the main and supporting facilities. This is done so that endowment disputes in the community can be resolved fairly and protect the parties to the dispute and save the endowment assets used by the community.

An Observational Study to Compare the Effect of Two Different Doses of Dexmedetomidine on Hemodynamic Response to Laryngoscopy and Endotracheal Intubation

Jatin B. Patel[1], Riddhi Agrawal[2], Malini Mehta[3]

[1]Associate Professor, [3]Professor, Department of Anaesthesiology, Dhiraj Hospital, SBKS MI & RC, Sumandeep Vidyapeeth, Piparia, Waghodia, Vadodara, Gujarat, India, [2]Registrar, University hospitals of North Midlands, Stoke on Trent, Staffordshire, United Kingdom

Abstract

Background: Laryngoscopy and intubation are associated with intensesympathoadrenal stimulation resulting in hypertension, tachycardia & arrhythmias consequent to the release of catecholamines. Various drug regimens and techniques have been used from time to time for attenuating the stress response to laryngoscopy and intubation, including opioids, barbiturates, benzodiazepines, beta blockers, calcium channel blockers, vasodilators etc. Dexmedetomidine is a highly selective alpha 2 receptor agonist having eight times higher affinity and alpha 2 selectivity compared to clonidine and has a shorter duration of action than clonidine.

Material and Method: 60 patients scheduled for elective surgical procedures under general anaesthesia belonging to ASA Grade I and II, in the age group of 18 to 60 years were divided into two study groups, D1 and D0.5 received dexmedetomidine 1 µg/kg and 0.5 µg/kg intravenously (iv) over 10 minutes before induction. Hemodynamic responses were compared in both groups by measuring Heart rate (HR),Systolic blood pressure (SBP),Diastolic blood pressure(DBP),Mean arterial pressure (MAP) and SpO_2 before giving the test drug (base line values),just before induction,during intubation and at 1 minute, 3 minutes, 5 minutes,10 minutes after intubation. Statistical data were analyzed by using student's unpaired t test.

Observation and Results: Group D1 had 4.70% rise in HR and Group D0.5 had 9.59% rise during intubation which was statistically significant($p<0.05$). Maximum rise in SBP and DBP in Group D0.5 was 14.53% and 12.84% respectively, whereas in Group D1 it was 5.55% and 8.90% respectively. In Group D0.5, rise in BP lasted longer after intubation compared to Group D1.

Conclusion: The present study demonstrated that ivdexmedetomidine 1µg/kg was better than dexmedetomidine 0.5µg/kg in attenuation of the pressor response of laryngoscopy and intubation without any significant side effects.

Introduction

Laryngoscopy and intubation are associated with intense sympathoadrenal stimulation resulting in hypertension, tachycardia & arrhythmias consequent to the release of catecholamine.(1) Patients with limited myocardial reserve, tachycardia and hypertension may result in myocardial ischemia, infarction (MI); arrhythmias or precipitate cardiac failure.(2) The hypertensive response may produce deleterious effects

in patients with raised intracranial pressures (ICP) or intraocular pressures (IOP), pheochromocytomas and vascular lesions such as intracranial arterio-venous malformations or those with aortic aneurysms and dissection.[2,3]

Various drug regimens and techniques have been used from time to time for attenuating the stress response to laryngoscopy and intubation, including opioids, barbiturates, benzodiazepines, beta blockers, calcium channel blockers, vasodilators etc.[4,5,6,7,8]

α2 adrenergic agonists namely clonidine and dexmedetomidine decrease sympathetic tone and preoperative use of clonidine has been shown to blunt the hemodynamic responses to noxious stimulation and to prevent overall hemodynamic variability.[9,10]

Dexmedetomidine is a highly selective α2 receptor agonist having eight times higher affinity and α2 selectivity and has a shorter duration of action than clonidine.[11,12]

Materials and Method

The study was conducted after obtaining permission from ethical committee in Dhiraj Hospital, S.B.K.S.M.I. & R.C. in department of anesthesiology. 60 patients of ASA I and II were allocated in 2 groups (n=30 in each group). They were included in the study only after obtaining a written informed consent. **Group D1**(n=30) received 1μg/kg and **Group D0.5**(n=30) received 0.5μg/kg body weight of dexmedetomidineiv over a period of 10 minutes.

Inclusion Criteria:

- Age between 18 years & 60 years
- ASA I and II.
- No known history of allergy, sensitivity to the study drugs
- Patient willing to sign informed consent.
- Mallampatti class I and II

Exclusion Criteria:

- Patient's refusal.
- ASA III and IV
- Known case of heart blocks, sinus bradycardia and hypotension, autonomic neuropathy
- Patients on beta blocker drugs
- Mallampatti class III, IV & V
- Allergy to trial drugs.
- Nasogastric tube insertion
- Patient undergoing procedures requiring head and neck manipulation

Patients were explained about the procedure of general anaesthesia and a written informed consent was obtained from them. Pre-operatively patient's history, systemic examinations and routine investigations were carried out.HR, SBP and DBP were recorded preoperatively.

Tab alprazolam 0.5 mg was given on the previous night of surgery and patients were kept nil by mouth overnight. In operation theatre multipara monitor was applied and baseline HR, SBP, DBP, SpO_2 and ECG were recorded. Intravenous line was secured and iv fluid was started.

All patients were premedicated with inj. ondansetrone 0.08mg/kg, inj. glycopyrrolate 0.004 mg/kg and inj. midazolam 0.05mg/kg iv.Group D1received dexmedetomidine 1μg/kg iv diluted in 50 ml normal saline using syringe infusion pump over 10 minutes. Group D0.5 patients were given intravenous dexmedetomidine 0.5 μg/kg iv diluted in 50 ml normal saline, using syringe infusion pump over 10 minutes.

After completion of dexmedetomidine infusion, patients were pre-oxygenated with 100% oxygen for 3 minutes. They were induced with 2.5% thiopentone sodium 5-7 mg/kgiv till the loss of eyelash reflex. Inj. succinylcholine 2mg/kg iv was given. Patients were intubated with appropriate sized cuffed endotracheal tubes. After checking the equal bilateral air entry endotracheal tube was fixed. Anaesthesia was maintained with oxygen and nitrous oxide (50%-50%), isoflurane and loading dose of inj. Atracuriumiv 0.5mg/kg and after that intermittent dose of 0.1mg/kg.

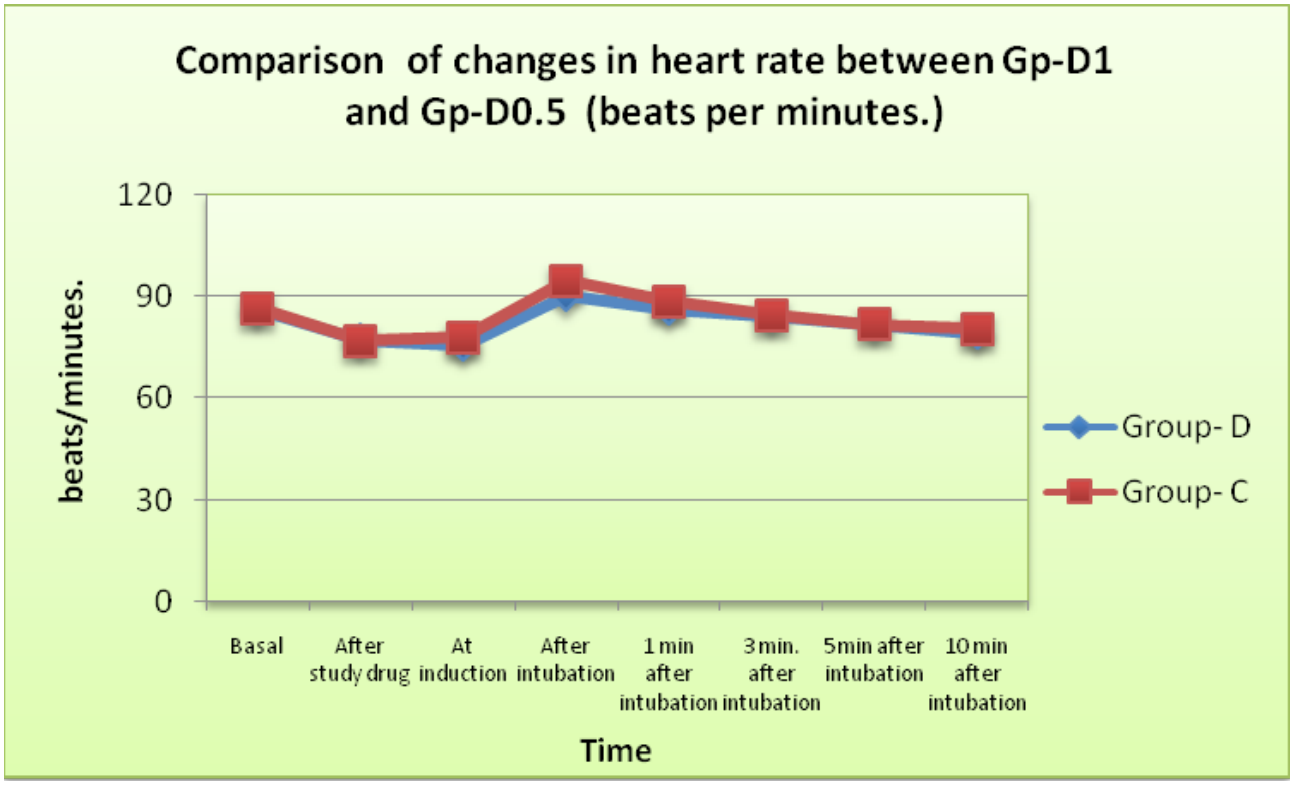
HR, SBP, DBP were recorded before giving the drug,just before induction of anaesthesia, during intubation and at 1 minutes, 3minutes, 5 minutes,10 minutes after intubation. After the surgical procedure was over, neuromuscular blockade was reversed with inj. neostigmine 0.05 mg/kg and inj. glycopyrrolate 0.008mg/kg iv. Once all recovery criteria were fulfilled trachea was extubated. Patients were monitored in the post-operative recovery room for 24 hours. They were observed for analgesia and side effects like nausea,

vomiting, sedation, respiratory depression, bradycardia and hypotension.

Observation and Results

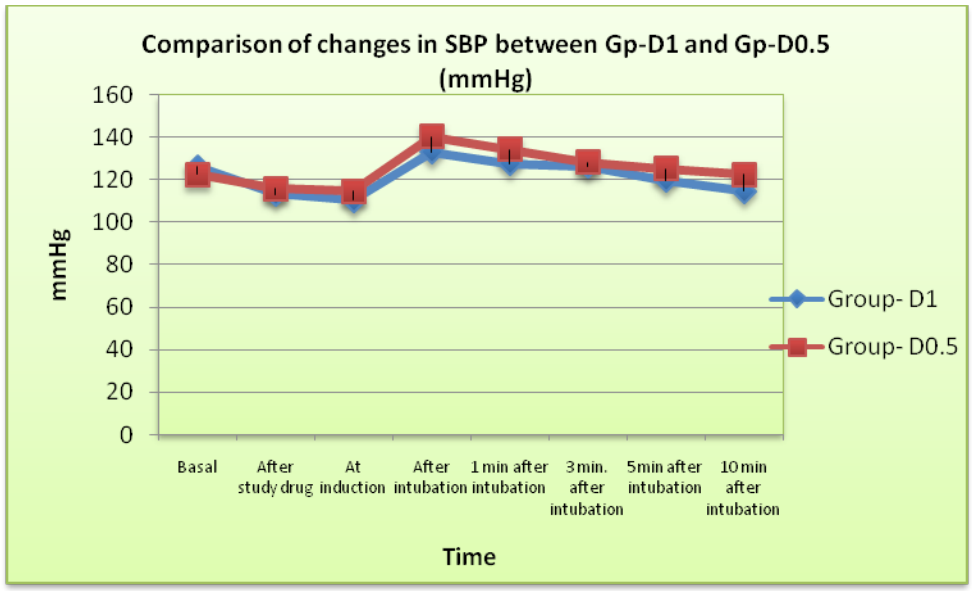
Statistical data were analyzed by using student's unpaired t test.

For age, weight, genderand ASA grade there was no statistically significant difference in patients of Group D1 and Group D0.5 (p >0.05)



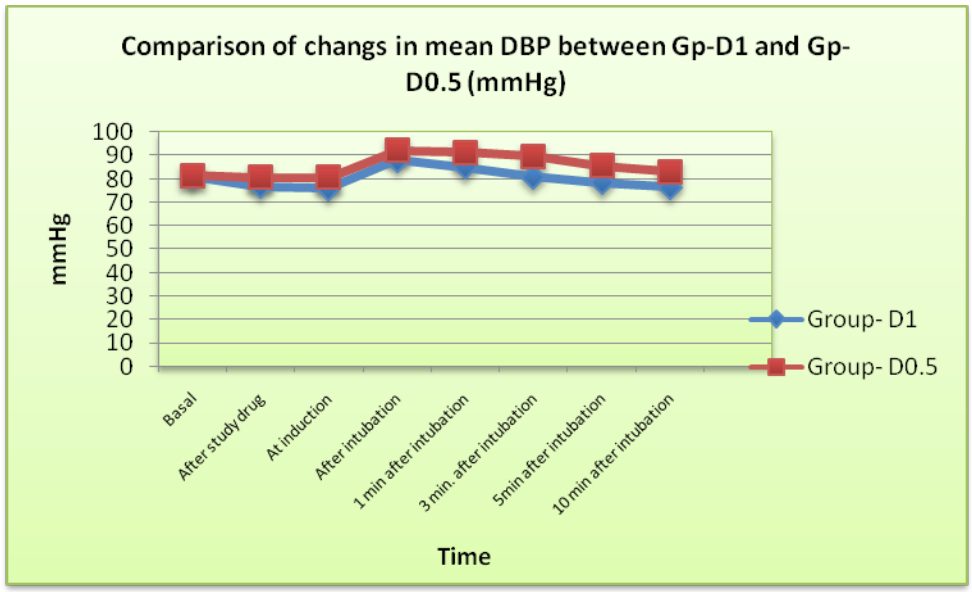
Graph 1: Showing Heart Rate at different time intervals in Group D1 and Group D0.5

Mean HR in Group D1 was 86.27±1.447 per minutes and in Group D0.5 it was 86.23±2.027 per minutes at baseline level, which was comparable (p>0.05). There was fall in HR in both Group D1 and Group D0.5. HR further decreased at induction in both groups. Group D1 had 12.36% fall whereas Group D0.5 had 9.74% fall from baseline value. In Group D1 at intubation mean HR was 90.33±1.431 per minutes showing 4.70% rise,whereas in Group D0.5 it was 94.50±0.5023 per minutes with 9.59% rise. The difference in mean HR between two groups was statistically significant (p < 0.05). Both groups showed maximum rise in HR during intubation but immediately after intubation it started decreasing. Rate of fall was almost equal in both groups till 5 minutes post intubation. At 10 minutes after intubation HR reached to 79.10±1.892 per minutes in Group D1 with 9.06% fall and in Group D0.5 80.40±1.650 per minutes with 6.76% fall. Difference in mean HR between two groups at any time interval was statistically insignificant (p> 0.05) except during intubation which was statistically significantly higher in group D1 than in group D0.5 (p < 0.05).



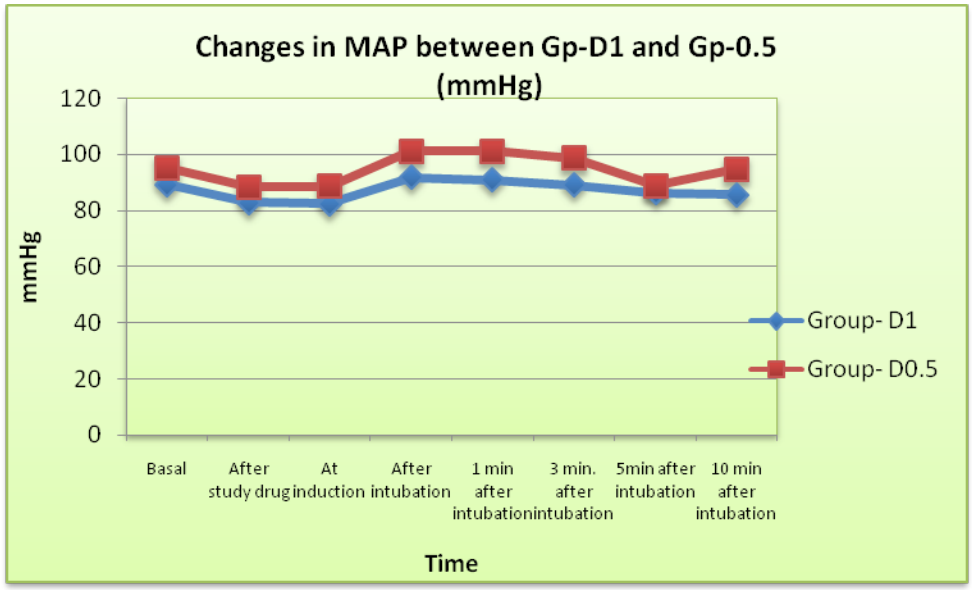
Graph 2: Mean SBP at different time interval in Group D1 and Group D0.5

At baseline mean SBP in Group D1 was 126.1± 1.281 mmHg and in Group D0.5 was 122.5±1.189 mmHg.There was fall in SBP from baseline value in both groups after study drug infusion and at induction but Group D1 had significant fall (12.7%) compared to Group D0.5 (6.19%) ($p<0.05$). During intubationin Group D1, it increased from 126.1± 1.281mmHg to 133.1± 0.913mmHg (5.55%) whereas in Group D0.5 it rose to 140.3±1.283mmHg from 122.5±1.189mmHg (14.53%). Difference in mean SBP between two groups was statistically highly significant ($p< 0.001$).SBP in both groups started falling immediately after intubation from its maximum level. In Group D1, at 5 minutes after intubation, SBP was below baseline value, whereas in Group D0.5 SBP remained higher than baseline value at 5 minutesand took 10 minutes to reach baseline value. Difference in SBP from 1 minute after intubation till 10 minutes post-intubation was statistically significant ($p< 0.05$).



Graph 3: Mean DBP at different time interval in Group D1 and Group D0.5

At baseline mean DBP in Group D1 was 80.87±1.679 mmHg and in Group D0.5 it was 81.53±1.049 mmHg. DBP in both groups decreased after study drug infusion and after induction. The difference was statistically significant ($p < 0.05$).There was maximum rise in DBP in both groups at intubation. In Group D1 it increased to 88.07±1.270 mmHg from its baseline value showing 8.9% rise whereas in Group D0.5 it went to 92.00±0.996 mmHg from basal DBP with 12.84% rise. This difference was statistically significant ($p < 0.05$). Immediately after intubation DBP in both groups started decreasing but the rate of fall in DBP in Group D1 was faster compared to Group D0.5 and at 3 minutes after intubation DBP in Group D1 was nearly same as baseline value. At 10 minutes post intubation DBP was 76.53±1.028 mmHg that was 5.36% lower than basal DBP, whereas in Group D0.5, DBP even at 10 minutes after intubation was higher than baseline DBP (83.13±1.137 mmHg).Difference in mean DBP between two groups at any time interval except at baseline was statistically significant ($p<0.05$).



Graph 4: Mean Arterial Pressure At Different Time Intervals Between Group D1 and Group D0.5

Mean arterial pressure at baseline in Group D1 was 95.94±0.848 mmHg and in Group D0.5 it was 95.52±0.925 mmHg which was comparable ($p>0.05$). There was fall in MAP in both groups after study drug infusion and after induction, which was statistically highly significant ($p<0.001$). In Group D1 MAP increased to 103.08±1.004 mmHg during intubation with rise of 7.00% from baseline value whereas in Group D0.5, the rise was 13.17%. The difference was statistically highly significant ($p < 0.0001$). In both groups after intubation MAP decreased from its maximum rise and in Group D1 at 3 minutespostintubation it reached to baseline level and at 10 minutes post intubation 7 % lower than baseline level but in Group D0.5, it remained above basal value even 10 minutes after intubation.Difference in MAP between two groups remained highly significant from time of intubation, till 10 minutes after intubation ($p< 0.0001$).Average dose of thiopentone used in Group D1 was 412.5±26.0 mg and in Group D0.5 it was 448.3±30.9 mg. The difference between two groups was statistically insignificant ($p>0.05$)

No side effects or complication were seen in any patients of either group.

Discussion

Laryngoscopy and endotracheal intubation are perceived as intense events during general anaesthesia. They give rise to a transient, but marked sympathoadrenal response. Therefore controlling this perioperative stress response is pivotal goal of anaesthesia practice [13]. Various pharmacological & non pharmacological method were evaluated either in premedication or during induction to attenuate these adverse stress responses but no single anaesthetic technique is effective in completely abolishing these responses. The drugs used were either partially effective or were with adverse effects.[14]

Dexmedetomidine offers a unique pharmacological profile with sedation, sympatholysis, analgesia, cardiovascular stability by altering the stress induced sympathoadrenal responses to intubation during surgery & during emergence from anaesthesia. Presynaptic activation of α2 adrenoceptor in the locus ceruleus in brain inhibits the release of nor epinephrine. In addition, the locus ceruleus is the site of origin for descending medullospinal noradrenergic pathway,known to be an important modulator of nociceptive neurotransmitter. Also, postsynaptic activation of α2 receptors in the CNS results in decrease in sympathetic activity leading to fall in heart rate.

We compared the efficacy of dexmedetomidine at a dose of 1μg/kg (Group D1) with 0.5μg/kg (Group D0.5) when administered over 10 minutes before induction of anesthesia in 30 patients of each group. The groups were comparable with respect to demographic factors like age, weight,gender. Baseline heart rate was comparable in both the groups. After 10 minutes of dexmedetomidine infusion, there was fall in heart rate in both the groups, Group D1>group D0.5. The fall continued even after induction in both the groups except during intubation. During intubation there was rise in heart rate in both the groups, Group D0.5 >Group D1. The difference being statistically significant ($p<0.05$).

Sagiroglu A et al[15] in 2009 and Sunil et al[16] in 2012 compared the effect of dexmedetomidine at two different doses i.e 0.5μg/kg vs 1μg/kg on attenuation of haemodynamic responses to laryngoscopy & intubation. They concluded that 1μg/kg is better in obtunding hemodynamic response to laryngoscopy. **Thus** comparable with our study.

Our study results were also in accordance with the results of **Yildizet al.[17] and Bijoy kumar panda et al**[18]. They too observed that dexmedetomidine when administered at a dose of 1μg/kg was able to suppress the heart rate response to laryngoscopy. SBP, DBP and MAP were better managed in the group receiving dexmedetomidine 1μg/kg.

Sagiroglu A**et al[15]** similarly observed that SBP, DBP and MAP values were lower post induction in both the groups of dexmedetomidine 1μg/kg and 0.5μg/kg, similar to the findings of our study.SBP and DBP were significantly lower at 60 seconds post intubation in dexmedetomidine 1μg/kg as compared to dexmedetomidine 0.5μg/kg.

Yildiz et al[17] also observed maximum increase in blood pressure immediately after intubation. During intubation increase in SBP in placebo group was 40% compared to 8% in the group of dexmedetomidine 1μg/kg. Also increase in DBP was 25% in placebo group as compared to 11% in the group of dexmedetomidine 1μg/kg.

The initial fall in blood pressure can be explained by peripheral α-2B adrenoceptors stimulation of vascular smooth muscles. The initial response is followed by further decrease in blood pressure. Both these effects are caused by inhibition of central sympathetic outflow overriding the direct stimulant effects.

Average requirement of thiopentone was noted during our study. The requirement was 8% less in the group receiving dexmedetomidine 1μg/kg when compared to dexmedetomidine 0.5μg/kg. The difference being not statistically significant($p>0.05$).Similar to our findings, **Bijoykumar panda et al**[18] has also observed statistically insignificant reduced requirement of thiopentone in dexmedetomidine group(1μg/kg) as compared to clonidine group (1μg/kg).

There was no side effect noted in our study.

Similarly, **Shirsedu et al**[19] have also not found any instability of vitals either with clonidine or dexmedetomidine . They compared clonidine at 2μg/kg with dexmedetomidine at 1μg/kg given over 10 minutes, in patients undergoing general surgery.

Bijoykumar panda et al[18] found bradycardia in only 2 patients out of 60 patients, using dexmedetomidine 1μg/kg when given over 10 minutes.

Belleville et al[20] found that dexmedetomidine which was given in 2 minutes at doses of 1-2μg/kg cause irregular ventilation and apnea episodes. Irregular breathing seen with high dose of 1-2 μg/kg probably related to deep sedation and anatomical features of the patient.

Such side effects were not seen in our study thus making dexmedetomidine at dose of 1μg/kg and 0.5μg/kg when given over 10 minutes to be free of side effects.

Conclusion

Dexmedetomidine at dose of 1μg/kg significantly attenuated the sympathetic response of laryngoscopy and intubation and also at dose of 0.5μg/kg reduced the

pressor response, but its effect was lesser than that of dexmedetomidine 1µg/kg. Thus this study showed that dexmedetomidine 1µg/kg is superior to dexmedetomidine 0.5µg/kg in the attenuation of hemodynamic response to laryngoscopy and endotracheal intubation with no side effects. Dexmedetomidine is helpful in decreasing the requirement of anaesthetic agent for induction.

Favipiravir, will it be the Answer for the Specific Management of COVID-19?: A Review

Jayant Patharkar[1], Maulin Mehta[2], Janhavi Patharkar[3]

[1]Assistant Professor, [2]Associate Professor,Department of Pharmacology, Smt. B.K. Shah Medical Institute & Research Centre, Sumandeep Vidyapeeth Deemed to be University, At. & Post. PIPARIA, Tal. Waghodia, Dist. Vadodara-391760, Gujarat State, [3]Assistant Professor, Department of Kayachikitsa, Parul Institute of Ayurved, At. & Post. Limda, Tal. Waghodia, Dist. Vadodara-391760, Gujarat state.

Abstract

Background: The COVID-19 has created havoc all over the world as no specific treatment available till date. Total COVID-19 cases had crossed 11,125,245 including 528,204 deaths as per the WHO data till 5 July 2020. Unfortunately, India secured third place in total tally of COVID-19 cases with 6,77,719 total cases including 19693 deaths as of 5th July 2020. The antiviral drug, Favipiravir, previously known as T-705 approved in Japan for treatment of Influenza. It is selective & potent inhibitor of viral RNA polymerase. It is promising drug for treatment of wide range of RNA viruses including SARSCoV-2.

Method: The systematic review of Articles was done with the help of search engines like Embase, Medline, PubMed & Google Scholar, clinicaltrials.gov. The Peer reviewed articles published through 6th of July 2020 were included in the study. This review was done to establish clinical evidence for use of Favipiravir in COVID-19.

Conclusion: It was found that due to lack of conclusive evidence, Favipiravir cannot be included in main armamentarium for COVID-19.

Keywords: *COVID-19 management, clinical trials review,Favipiravir, repurpose drug.*

Introduction

The COVID-19 has created havoc all over the world as no specific treatment available till date. Total COVID-19 cases had crossed 11,125,245 including 528,204 deaths as per the WHO data till 5 July 2020[1]. Unfortunately, India secured third place in total tally of COVID-19 cases with 6,77,719 total cases including 19693 deaths as of 5th July 2020[2].

The antiviral drug, Favipiravir, previously known as T-705 approved in Japan for treatment of Influenza. It is prodrug of a purine nucleotide i.e. Favipiravir ribofuranosyl-5'-triphosphate. It is selective & potent inhibitor of viral RNA polymerase. Thus, it halts the viral replication. It is effective against all strains of influenza viruses. It is promising drug for treatment of wide range of RNA viruses including SARSCoV-2[3,4].

At present, there is no robust evidence from randomised clinical trials (RCTs), that specific drug or treatment will improve the patient outcome of COVID-19. Thus, various treatment modalities, repurposed or experimental drugs are under the clinical trials for establishing evidence based specific treatment for novel corona virus epidemic. The repurposed drugs under such clinical trials are Chloroquine phosphate, hydroxychloroquine sulfate, Lopinavir/ritonavir, Umifenovir (Arbidol), Remdesivir, Favipiravir, Tocilizumab[5].

Hence, this review was proposed for Flavipiravir, to understand current & future prospect of this promising antiviral drug by summarizing various clinical trials, studies & analysing the outcome of these studies.

Method

The systematic review of Articles was done with the help of search engines like Embase, Medline, PubMed & Google Scholar, clinicaltrials.gov. The Peer reviewed articles published through 6th of July 2020 were included in the study. The Search words used in combinations included; COVID-19, Favipiravir, Antiviral, COVID-19 specific treatment options, repurposed drugs, Randomized Clinical Trials (RCTs)

All the studies, randomized clinical trials, cohort, prospective, metanalysis, review was included in for the review, keeping the goal as to ascertain the role of Favipiravir in the management of COVID-19.

Results

Various studies conducted for COVID-19 patients treated with Favipiravir:

1. The Clinical Trials gov Identifier: NCT04349241 by Hany Dabbous, Ain Shams University in 2020, sample size was 100 & intervention was Favipiravir. The out come of this trial is not available
2. A Randomized Clinical Trial: Favipiravir versus Arbidol for COVID conducted by Chang Chen, Ping Yin, Yi Zhang, Jianying Huang et al. in 240, sample size was 240 & intervention was Favipiravir, Arbidol. In this trial they found that Favipiravir significantly improved the latency to relief for fever and cough.
3. An Open-Label Control Study for COVID: Experimental Treatment with Favipiravir by Cai a Qingxian,y, Minghui Yang a,y, Dongjing Liu a,y, Jun Chen a,y, Dan Shu a, Junxia Xia a, Xuejiao in the year 2020. The sample size was 80 with intervention used Favipiravir (FPV) versus Lopinavir (LPV)/ ritonavir (RTV). In this study significant difference observed (p=0.004) in radiological parameters like chest imaging when favipiravir used against control group.
4. The ClinicalTrials.gov Identifier: NCT01068912 conducted by MDVI, LLC in year 2015, in sample of 530, wherein they used Favipiravir against placebo comparator. In this trial they found that the Adverse drug reactions, deaths were not seen in influenza patients when favipiravir used & it was proved to be effective for different doses.
5. The ClinicalTrials.gov Identifier: NCT02026349 by MDVI, LLC in 2015 among 860 patients found that the patients of influenza were cured of symptoms like temperature without any untoward side effects with favipiravir.
6. The Clinical trial, Identifier: NCT04376814 conducted by Baqiyatallah Medical Sciences University among 40 patients, wherein favipiravir compared with another arm having Hydroxychloroquine, Lopinavir/Ritonavir. The result of this trail was not reported.
7. The Bioequivalence Study of Favir 200 mg Film Tablet Kocak Under Fasting conditions, Clinical trials gov Identifier NCT04444986 by Kocakfarma in 2020 among 30 patients using Favir 200 mg FT against Avigan 200 mg FT. The result of study was not reported.
8. A Review: Pharmacologic Treatments for Coronavirus Disease 2019 was conducted by James M. Sanders, L. Monogue, Marguerite et al. in 2020 found that no therapies have been shown effective to date.
9. A systematic review and meta-analysis: Efficacy and safety of antiviral treatment for COVID-19 from evidence in studies of SARSCoV-2 and other acute viral infections conducted by Wei Liu, Pengxiang Zhou, Ken Chen, Zhikang Ye, Fang Liu, et al. in 2020 found that presently no existing antiviral treatment beneficial.
10. A Review Pharmacological Therapeutics Targeting RNA-Dependent RNA Polymerase, Proteinase and Spike Protein: From Mechanistic Studies to Clinical Trials by JianshengHuang, Hui Huang Wenliang Song in 2020 commented that with the development of potent & effective RdRp inhibitors will be useful in SARS-CoV-2 therapy.

Discussion

The Favipiravir, repurposed drug for COVID-19 treatment. It has been the approved drug for use in the influenza in Japan. Favipiravir is a prodrug which is converted intracellularly into phosphoribosylated form-active form. This active form is recognized as a substrate by the viral RNA-dependent RNA polymerase. & replication of virus can be prevented [6].

In the Clinical trials registries, total 21 studies have been registered for use of Favipiravir in COVID-19 patients. Out of these studies three studies are completed & only two studies result has been published. Out of these two studies, the multi-centric phase II trial (NCT01068912), has shown clinical efficacy of Flavipiravir in Influenza. This study also posted that the clinical efficacy can be seen in low-dose as well as high-dose regimens, no serious adverse events has been witnessed [7]. In another study, which posted result (NCT02026349), it was noted that favipiravir could reduce symptoms and fever could be subsided without any adverse events [8].

In the randomized controlled trial conducted by Chang Chen et al.in March 2020, found that the patient had relieved of pyrexia & cough in short span of time with Favipiravir significantly, but no significant change has been seen in clinical recovery rate as compared to Arbidol.

An Open-Label Control Study conducted with favipiravir & control arm with Lopinavir/ritonavir in COVID-19 patients elucidated that radiological improvement seen when viral load was reduced early. It is noteworthy that less adverse events occurred with Favipiravir than control arm having Lopinavir (LPV)/ ritonavir (RTV). In this trial treatment Favipiravir given orally (200 mg per tablet), dose 1600 mg two times in a day on first day & two times in a day for next thirteen days. The Lopinavir (200 mg)/Ritonavir (50 mg) were taken through enteral route, two tablets each two times in a day. On first day & then maintained for next thirteen days two times in a day[9]. Thus, in this study, efficacy in reducing viral load as well as safety of favipiravir over Lopinavir/ritonavir can be ascertained in the patients of COVID-19.

A treatment review by James M. Sanders et al. of Coronavirus disease found that, the preclinical data obtained about favipiravir was from its activity against influenza & Ebola virus. In Vero E6 cells, in vitro studies, the EC50 of favipiravir against SARSCoV-2 was 61.88 μM/L[10]. The doses would differ according to type of infection. Thus, for COVID-19, higher dosing range was selected i.e. a maintenance dose (1200 mg to 1800 mg every 12 hours) after loading dose (2400 mg to 3000 mg every 12 hours × 2 doses)[11,12]. Favipiravir is being used in influenza in Japan but it is not available in the united states. Thus, to establish the evidence for use of favipiravir in the SARSCo-2, more RCTs has to be conducted in near future[5].

A systematic review & meta-analysis about the efficacy & safety of antiviral drugs in COVID-19, stated that there is no evidence present currently to confirm important benefits of antiviral treatment but still did not strike out important benefits of individual antiviral agent[13].

Jiansheng Huang revived about target proteins like RNA-Dependent RNA Polymerase, spike proteins & proteinase in various clinical trials and studies being conducted during this COVID-19 pandemic and on the basis of mechanism of replication of SARS-CoV-2 RNA-Dependent RNA Polymerase, found that effective & potent RdRp inhibitors may play key role in the treatment of COVID-19[14]. At present Favipiravir, inhibitor of RNA polymerase is used for influenza in Japan. However, the safety issue about favipiravir should be kept in mind because of its teratogenic risk though this broad-spectrum antiviral seems promising.

Conclusion

The Favipiravir, repurpose drug, had shown promising results in COVID-19 in few of the studies but vast majority of clinical trials are ongoing. Hence at this juncture, it will be overambitious to put Favipiravir as front warrior against COVID-19. Thus, due to lack of conclusive evidence, Favipiravir cannot be included in main armamentarium for COVID-19.

Glycemic Control of Non-Hodgkin Lymphoma (NHL) Non-Diabetes Mellitus (DM) Patient in the First CHOP Chemotherapy

Jualita Heidy Saputri[1], Hermina Novida[2], Ami Ashariati[3]

[1]Resident, Department of Internal Medicine, Dr. Soetomo Teaching Hospital, Airlangga University Faculty of Medicine, Indonesia, [2]Lecturer, Division of Endocrinology, Diabetes, and Metabolism, Department of Internal Medicine, Dr. Soetomo Teaching Hospital, Airlangga University Faculty of Medicine, Indonesia, [3]Professor, Division of Medical Oncology, and Hematology, Department of Internal Medicine, Dr. Soetomo Teaching Hospital, Airlangga University Faculty of Medicine, Indonesia

Abstract

Non-Hodgkin's lymphoma (NHL) chemotherapy is cyclophosphamide, doxorubicin, vincristine, and prednisone (CHOP) have hyperglycemia side effects that affect the success of chemotherapy. Improved glycemic control decreases morbidity and mortality. Determine the glycemic control changes in non-DM NHL patients before and the sixth day after the first CHOP chemotherapy.

Method: Prospective longitudinal observational analytic study in the Internal Medicine Inpatient Unit Dr. Soetomo Teaching Hospital Surabaya, involved all the first CHOP chemotherapy NHL patients during November 2019-February 2020. A total of 21 patients met chemotherapy requirements and were not DM. The glycemic control check uses the hexokinase method and a glucometer (Easy Touch®). Data analysis using the Wilcoxon test was considered significant if $p < 0.05$.

Results: Total research subjects were 21 people, female domination (66.7%), mean age 49.24 ± 13.96 years, clinical stage 3 dominance (52.38%), mean HbA1C 5.75 ± 0.49%, average FBG 90.86 ± 13.13 mg/dL, the mean PPBG 114.33 ± 20.16 mg/dL. Daily blood glucose levels during chemotherapy were highest on the first day's pre-dinner. There were significant differences in FBG and PPBG before chemotherapy and the sixth day after chemotherapy (p-values 0.032 and 0.002). The incidence of new-onset DM on the sixth day after the first CHOP chemotherapy was 2 subjects (9.53%).

Conclusion: There was an increase in FBG and PPBG of NHL non-DM patients before and the sixth day after the first CHOP chemotherapy.

Keywords: *NHL, DM, CHOP.*

Introduction

Malignant lymphoma is the primary malignancy of lymph nodes and lymphoid tissue. Based on the presence of Reed-Sternberg cells, they are divided into Hodgkin's lymphoma (HL) and non-Hodgkin's lymphoma (NHL)[1]. One of the ten most severe malignancies in the world is malignant lymphoma with a prevalence of 3.37%. Its incidence worldwide has increased by 3-4% in the last 4 decades with the incidence of NHL 6% in men and 4.1% in women[1-2]. In America there are 74,200 new cases (4.2%), 19,970 (3.3%) of whom died from NHL, and life expectancy for the next 5 years by 72%[3]. Ministry of Health of the Republic of Indonesia in 2013, the incidence of lymphoma in Indonesia was 0.06% with an estimated 14,905 patients and 2,296 of them were

Corresponding Author:
Dr. Hermina Novida
Lecturer, Division of Endocrinology, Diabetes, and Metabolism, Department of Internal Medicine, Dr. Soetomo Teaching Hospital, Airlangga University Faculty of Medicine, Indonesia
e-mail: herminanovida@ymail.com

from East Java Province[1]. This data shows that NHL is a common malignancy with sufficient mortality and high life expectancy. Therapeutic modalities in NHL patients are chemotherapy and radiation. The choice of first-line chemotherapy is a combination of cyclophosphamide, doxorubicin, vincristine, and prednisone (CHOP)[4-5].

One of side effect CHOP chemotherapy is hyperglycemia[5-6]. Hyperglycemia is a condition of an increase in blood glucose more than normal that can progressively become a metabolic disease (diabetes mellitus/DM). A 2013 Japanese study stated that 32.5% of patients with NHL without a history of DM who received CHOP chemotherapy will become DM[7]. In the same year, a study in Mexico revealed 40.6% of the DM's incidencein NHL patients and acute lymphoblastic leukemia due to the use of high-dose glucocorticoids associated with chemotherapy[8]. In 2018, research in the USA stated that 47% of NHL patients experienced episodes of hyperglycemia in the first week after RCHOP or REPOCH chemotherapy[9].

Hyperglycemia is influential on the quality of human resources and has an impact on a significant increase in health costs[10-11]. Chemotherapy-related hyperglycemia can cause acute complications in the form of infections, sepsis, ketoacidosis (3.6%), hyperosmolar non-ketotic (7.2%), acute hyperglycemia syndrome, and dehydration[11-15]. In addition, hyperglycemia can affect the result of chemotherapy, the rate of cancer recurrence, and resistance to chemotherapy agents. Blood glucose control during chemotherapy is important in terms of success chemotherapy, life expectancy of cancer patients, reducing morbidity, mortality, and affects decreasing health insurance financing[13-14,17]. Components assessed were glycemic control in the form of fasting blood glucose (FBG) and 2 hours postprandial blood glucose (PPBG) when the patient was before chemotherapy and evaluated after getting the first CHOP chemotherapy.

Material and Method

This was aprospective observational study with pre and posttest design. The population of this study was NHL patients who have been diagnosed and come for chemotherapy in the internal medicine ward of Dr. Soetomo general hospital, Surabaya. Sample size calculated from the following formula: $n = \left[\frac{(Z\alpha+Z\beta)s}{x1-x2}\right]^2$, which standard deviation from the previous study was 0.64 and a confidence interval of 95% therefore, a minimum of 17 subjects needed. Subjects were recruited totally. Subjects with DM type 2 in the first screening, under certain medication (corticosteroid, antioxidant), had an adverse event or serious adverse event during the procedure, or refuse to join this study were excluded from this study. All cases included in this study were subjected to complete informed consent, clinical history, clinical evaluation, sampling blood vein, and capillary blood. Three mL blood vein samples were collected from the subjects in the morning (8 – 10 a.m.), under fasting conditions for at least 8 hours for FBG, lipid profile, and HbA1C. Then subjects had breakfast, fasting again in 2 hours, and 3 mL blood vein samples were collected again for PPBG. This procedure in a day before chemotherapy (the first-day) and the sixth-day chemotherapy. During the procedure of chemotherapy, the subject had capillary blood sampling 15-30 minutes before breakfast, lunch, dinner, and bedtime.

Glycemic control was an examination of glucose levels consisting of fasting blood glucose (FBG) and 2-hour postprandial blood glucose (PPBG)[10]. Pre-meal (before breakfast, lunch, and dinner) and bedtime glucose were also components of glycemic control will be examined in this study. If in the duration of the study an increase in blood glucose is found, it will be consulted to the endocrine, metabolic, and diabetic divisions to determine whether DM or not and to determine whether interventions that are following the IEA 2019 standards are to be followed throughout the study period.

Fasting blood glucose (FBG) is a glucose level that is checked in fasting for 8 hours. Normal result if less than 100 mg/dL. Postprandial blood glucose (PPBG) is a glucose level that is checked in the condition after eating in regular portions (equivalent to 75 grams of glucose) and followed by fasting for 2 hours. Normal result if it is less than 140 mg/dL. HbA1C is the level of glycated hemoglobin in the blood that is examined in a state of fasting for 8 hours. Normal result if it is less than 5.7%. Prediabetes if obtained FBG 100-125 mg/dL, PPBG 140-199 mg/dL, and/or HbA1C 5.7-6.4%. DM if FBG> 126 mg/dL, PPBG > = 200 mg/dL, and/or HbA1C> = 6.5%[10]. Venous blood sampling was around 3 mL and processed using a *Dimension Exl* device with the hexokinase method in the clinical pathology laboratory Dr. Soetomo Surabaya.

Pre-meal glucose levels are glucose levels that are checked 15-30 minutes before a large meal in the morning, afternoon, and evening. Glucose bedtime is a glucose level that is checked before going to bed at

night. Results are considered normal when 80-99 mg/dL in non-DM individuals[18]. Data were obtained from supporting examinations in the form of capillary blood collection which were processed using an *Easy Touch®* glucometer.

CHOP chemotherapy (cyclophosphamide/doxorubicin/vincristine/prednisone) is the first-line regimen for NHL patients recommended by the Ministry of Health and/or NCCN for NHL patients for the first time. Doses given cyclophosphamide 750 mg/m^2 body surface area (BSA)/day/intravenously, doxorubicin 50 mg/m^2 BSA/day/intravenously, vincristine 1.4 mg/m^2 BSA/day/intravenously for the first day, and prednisone 60 mg/m^2 BSA/day/orally for 5 days per cycle[4-5]. Premedication was given before chemotherapy includes dexamethasone 10 mg intravenously, diphenhydramine 10 mg intravenously, and ondansetron 8 mg intravenously. Intravenous chemotherapy agents are given in the afternoon. Prednisone is given on the first day at 5.00 p.m. On days 2, 3, 4, and 5 prednisone is given at 7.00 a.m.

Chemotherapy requirements include performance status with a karnofsky score of more than 60%, hemoglobin more than 10 g/dL, leukocytes more than 4,000/mL, platelets more than 100,000/mL, serum transaminases are not more than 1.5 times the normal price, albumin is more than or equal to 2.5 g/dL, creatinine clearance of more than 70 mL/min[19]. Besides, research subjects were also screened for HIV infection, hepatitis B and Cvirusesinfection, and tuberculosis infections.

Statistical analysis performed using SPSS for Windows version 22.0. Univariate analysis performed to describe the characteristics of the subjects. Bivariate analysis performed using T-tests if data is normally distributed otherwise, the Wilcoxon test will be used. The normality test performed using the Shapiro-Wilk test.

Results

The total number of NHL patients who received the first CHOP chemotherapy during the period November 2019 - February 2020 and met the inclusion criteria was 21 patients. Subjects were dominated by female sex (66.7%), while male sex was 33.3%. The average age of the study subjects was 49.24 ± 13.96 years. In men, the average waist circumference is 86 ± 5.89 cm. In women, the average waist circumference was 94.14 ± 16.31 cm. The average body mass index (BMI) was 23.45 ± 4.72 kg/m2 with the domination of normal BMI was 7 subjects (33.3%). The dominance of NHL clinical stage 3 based on Ann Arbor was 11 people (52.38%). Median total cholesterol is 163 mg/dL, median triglyceride is 136 mg/dL, median HDL is 34 mg/dL, and mean LDL is 108.52 ± 20.92 mg/dL. Characteristics of HbA1C with an average of 5.75 ± 0.49%. The average research subject's FBG and PPBG was 90.86 ± 13.13 mg/dL and 114.33 ± 20.16 mg/dL. Risk factors for increased glycemic control include overweight - obesity by 8 subjects, dyslipidemia by 15 subjects, hypertension by 5 subjects, and smokers by 3 subjects.

Table 1. General characteristics of the subjects

Characteristic		n (%)	Average ± SD*	Median**	Range
Gender*	Male	14 (66,7)			
	Female	7 (33,3)			
Age**	18-60 years	18 (85,7)	49,24 ± 13,96		27-77
	More than 60 years	3 (14,3)			
Waist Circumferences*	Female		94,14 ± 16,31		65-122
	Less than 80 cm	2 (14,3)			
	More than 80 cm	12 (85,7)			
	Male		86 ± 5,89		80-96
	Less than 90 cm	5 (71,4)			
	More than 90 cm	2 (28,6)			

Characteristic		n (%)	Average ± SD*	Median**	Range
Body Mass Index (BMI)*	Less than 18,5 Kg/m^2	5 (23,8)	23,45 ± 4,72		16-35,4
	18,5 – 25,0 Kg/m^2	8 (38,1)			
	25,0 – 30,0 Kg/m^2	7 (33,3)			
	More than 30 Kg/m^2	1 (4,8)			
Clinical Staging of NHL*	Stage I	2 (9,52)			
	Stage II	7 (33,33)			
	Stage III	11 (52,38)			
	Stage IV	1 (4,76)			
Lipid Profile	Choleteroltotal*			163	121-304
	Trigliserida*			136	45-478
	HDL*			34	14-156
	LDL**		108,52 ± 20,92		74-140
HbA1C**			5,75 ± 0,49		4,6-6,4
FBG**			90,86 ± 13,13		73-122
PPBG**			114,33 ± 20,16		85-155

The effect of chemotherapy on FBG and PPBG levels in this study was statistically significant (p = 0.032 and p = 0.002) with a significance level of 5%. In our study, the average increase in FBG was 177.5 ± 28.99 mg/dL and PPBG 239.5 ± 58.69 mg/dL.

Table 2. Characterics of the subjects associated with glycemic control

Blood Glucose		Median (Minimum- Maksimum)	P-Value
FBG	Day 1	87 (73-122)	0,032
	Day 6	96 (76-198)	
PPBG	Day 1	113 (85-155)	0,002
	Day 6	126 (98-281)	

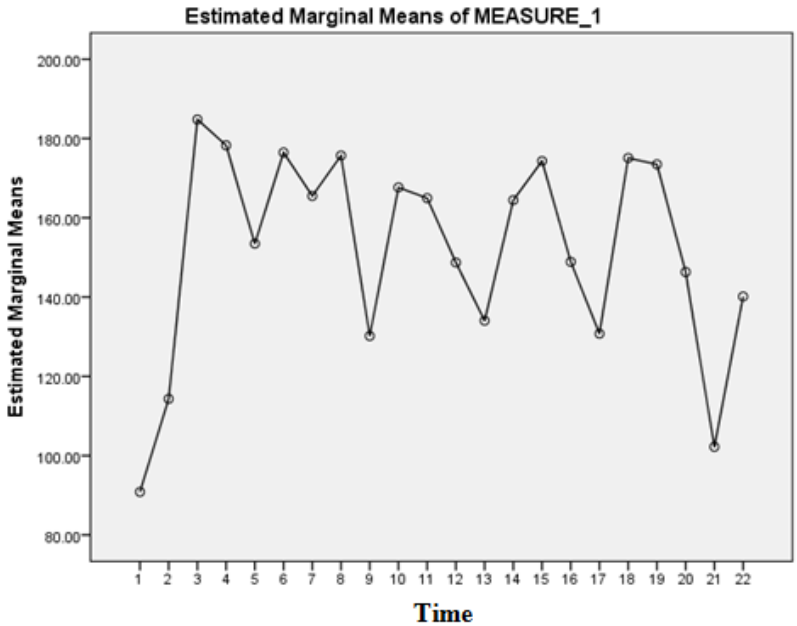

Figure 1. Trend analysis of *Anova Repeated Measurement* glycemic control's subjects

Figure 1 shows a trend graph analysis of Anova Repeated Measurement glycemic control of subjects. The graph above shows the peak increase in blood glucose levels during the first day's pre-dinner. Daily glycemic control is dominated by an increase in pre-lunch blood glucose levels which is then followed by a decrease at pre-dinner, bedtime, and pre-breakfast the next day.

Figure 2 shows the number of subjects who had diabetes, pre-diabetes, and normally based on FBG, PPBG, and/or HbA1C before chemotherapy and the sixth day of chemotherapy. Before chemotherapy, there were 5 subjects with pre-diabetes and 16 non-diabetic. On the 6th day of chemotherapy, there were 2 new DM incidents (9.53%) and 7 with prediabetes (33.33%).

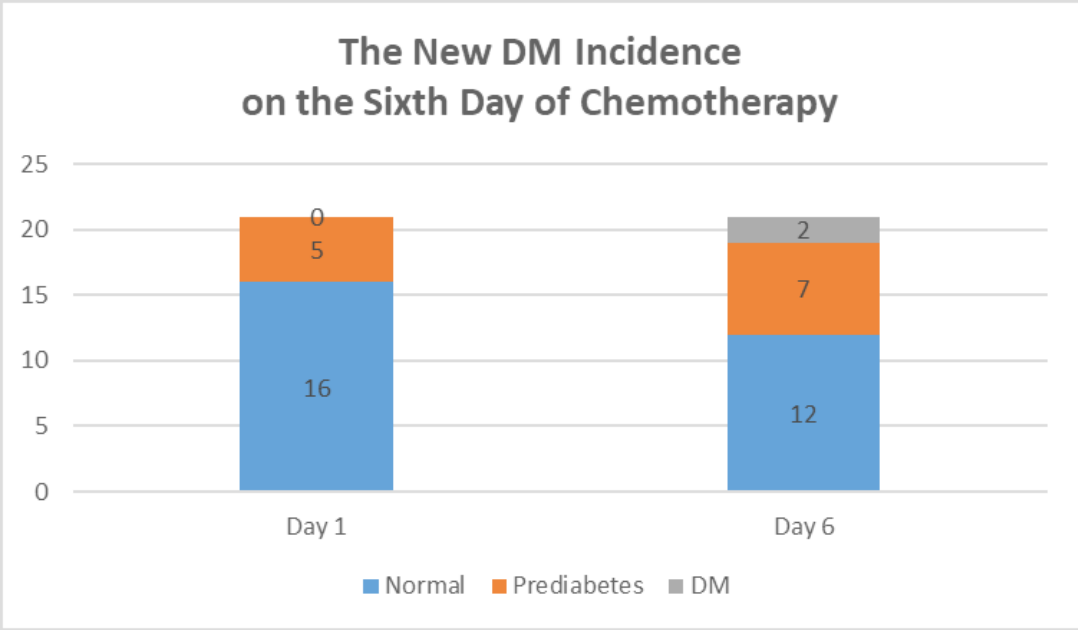

Figure 2. Incidence of DM in the sixth day of chemotherapy

Discussion

Glycemic control on the first day until the fifth day of chemotherapy was varied on the subjects. The examination is carried out to determine the peak increase in blood glucose levels so that early detection and intervention can be done. The peak during pre-dinner the first day of chemotherapy-related to the administration of CHOP agents and premedication in the form of dexamethasone. The dominance of increased daily blood glucose levels at pre-lunch and pre-dinner and back down at bedtime and pre-breakfast the next day. This shows the predominance of an increase in blood glucose levels after the administration of chemotherapy agents at 7.00 am on the second to the fifth chemotherapy day. The results of this study are in line with the theory presented in the study of Lee et al (2013) that an increase in glucose occurs after 6-8 hours after the chemotherapy agent is given and dominate more on increasing PPBG. Prednisone has a medium service life, peak concentration in plasma at 1 hour after administration, the half-life of 2.5 hours, can give a hyperglycemic effect with an onset of 4 hours, reaches a peak at the 8th hour of administration, and working duration of 12-24 hours[20]. Dexamethasone has a longer working time of 36-72 hours so that the effects of hyperglycemia can extend to the time of the next glucose level examination. This causes dexamethasone to dominate more on increasing FBG[21-22].

The effect of chemotherapy on FBG and PPBG levels in this study was statistically significant ($p = 0.032$ and $p = 0.002$) with a significance level of 5%. This is in line with research by Gonzales et al (2013), an increase in FBG in 50% of subjects and PPBG in 20% of subjects. The average increase in FBG was 7.08 ± 3.04 mmol/L and PPBG was 11.33 ± 0.3 mmol/L[8]. In our study, the average increase in FBG was 177.5 ± 28.99 mg/dL and PPBG 239.5 ± 58.69 mg/dL.

In this study, we found 2 subjects (9.53%) had new DM after getting chemotherapy. The two subjects did not experience acute complications of DM and were referred to Diabetes Mellitus Polyclinic of Dr. SoetomoTeaching Hospital Surabaya. Both of these subjects had comorbid factors such as for overweight, dyslipidemia, hypertension, and pre-diabetes. Subjects who had risk factors for pre-diabetes, had hyperglycemia up to 414 mg/dL, febrile neutropenia, and were given insulin therapy. Whereas subjects who did not have pre-diabetes risk factors received anti-diabetes drug therapy orally. Both subjects experienced a peak increase in glucose levels at the fourth and fifth pre-lunch in accordance with previous studies that mentioned an increase in the dominant glucose level at pre-lunch and depending on the dose accumulation of agents that cause hyperglycemia[7,9].

Some chemotherapy agents affect insulin resistance and β cells. This is exacerbated by the presence of comorbidities in patients such as obesity, hypertension, and metabolic syndrome. Risk factors in this study included overweight - obesity (8 subjects), dyslipidemia (15 subjects), hypertension (5 subjects), and smokers (3 subjects). The accumulation of the duration and dose of the chemotherapy agent also influences the incidence of DM[7]. In addition, according to Lamar et al (2018), hyperglycemia can be induced by drugs through the mechanism of pancreatic β cell destruction which causes a decrease in insulin secretion and sensitivity to insulin[9].

Cyclophosphamide and epirubicin can cause immunologically destructive β cells through induction of secretion of alpha interferon and lymphocytes cytokines[23]. Doxorubicin causes worsening of insulin signaling, muscle atrophy induces pro-inflammation and induces anaerobic glycolytic metabolism in skeletal muscle[24]. Corticosteroids induce hyperglycemia through decreased glucose transporter type 4 (GLUT-4) regulation in cell membranes, increased gluconeogenesis, insulin resistance in muscle cells and adipose tissue, β cell dysfunction, increased proteolysis and lipolysis, and inhibition of the enzyme 11-β hydroxysteroid dehydrogenase type 1[12,15,25-26].

Hyperglycemia contributes to the phenotype of cancer cell malignancy such as increased proliferation ability, apoptosis inhibition, metastasis, perineural invasion, resistance to chemotherapy through reducing the sensitivity of cancer cells to chemotherapy agents, and intolerance to chemotherapy[27-28]. The condition of hyperglycemia in malignant patients can affect the outcome of malignant therapy, complications related to malignancy and treatment of malignancy, length of stay, recurrence, and mortality[29-30]. Regulation of blood glucose levels isimportant in malignant patients[13-14,17]. It's related to the success of chemotherapy given, reducing the complications that may occur, reducing hospitalization days, reducing mortality, increasing the success rate of therapy, and life expectancy of cancer patients[7,8,9].

Conclusion

The peak of blood glucose during the first CHOP chemotherapy was in pre-dinner in the first day of chemotherapy. There was an increase in FBG and PPBG of NHL non-DM patients before and the sixth day the first CHOP chemotherapy. Incidence of new DM in the first CHOP chemotherapy was 9.53%.

Reformulation of Medical Rehabilitation against Victims of Narcotics Abuse in Indonesia

Jumriani Nawawi[1], Slamet Sampurno[2], M. Syukri Akub[2], Nur Azisa[3]

[1]Lecturer at Institut Agama Islam Negeri Bone (IAIN) Bone, South Sulawesi, Indonesia, [2]Professor, Department of Criminal Law, Faculty of Law, Hasanuddin University, Indonesia, [3]Associate Professor, Department of Criminal Law, Faculty of Law, Hasanuddin University, Indonesia

Abstract

The criminal sanction that occurred against the perpetrators of narcotic users is still inclined to apply imprisonment rather than rehabilitation measures. The research is a normative legal research using a statute, case, and conceptual approaches. The results show that The essence of medical rehabilitation sanctions imposing against victims of narcotics abusers who adhere to the double track system which is oriented to criminal and action sanction. Rehabilitation of narcotics abusers and addicts the purpose to cure the narcotics dependence against abusers and addicts so that the abusers and addicts recover from narcotics. In order to realize a narcotics-free State, the implementation of medical rehabilitation sanction imposing must reflect philosophical, juridical and sociological values while considers the legal development and needs of the community in implementing narcotics crime eradication.

Keywords: *Drugs;Narcotics; Rehabilitation; Victims.*

Introduction

Indonesia affirms firmly through its commitment to combat narcotics abuse and illicit trafficking, various specific regulations regarding narcotics in the form of laws have been made with the aim of combating narcotic crimes.[1] Although narcotics are substances or drugs that come from plants or not plants, synthetic and semi-synthetic that can cause a decrease and change of consciousness, loss of pain and can cause dependence.[2] On the one hand, the availability of narcotics is a useful drug in the field of medicine or health services and the development of science, but on the other hand it creates a very detrimental dependency if it is misused.To prevent and eradicate the misuse and illicit trafficking of narcotics that have been detrimental to and endanger the lives of the people, the assertion of the need for crime prevention is integrated with the overall social policy and national development planning.[3]

The role of rehabilitation in healing addictions for narcotics addicts is very important, because of the increasing number of narcotics addicts.[4] The effectiveness of rehabilitation to cure victims of narcotics is very necessary, given the difficulty of victims or users of narcotics to be separated from narcotics addiction individually. In rehabilitating drug addicts, the National Narcotics Agency cooperates with various parties includes foundations, hospitals and health centers. The addicts are rehabilitated so they can be free from the snare of drugs and return to normal life. Rehabilitation is important to do because the abuse of narcotics will have a negative impact on health, such as HIV-AIDS, hepatitis, infections, heart disease, blood vessel disorders in pregnancy and other health problems to death.

Based on previous research, it was found that neighboring country, Malaysia had first placed its citizens categorized as drug users as victims and no longer as perpetrators of crime. In Malaysia, drug users or addicts receive verdicts for rehabilitation even with a maximum limit of 3 times. Another example is Portugal, the country has decided that drug addicts who are intended as drug owners for their own use remain prohibited, but violations of this rule will be considered administrative violations, and no longer considered crimes. From various writings, it is known that in these two countries, there was then a decrease in the number of drug users, a decrease in mortality due to drug use

and a decrease in HIV-AIDS cases. This is precisely the case with Indonesia, where each year there is an increase in the number of drug use, the overload of correctional facilities with prisoners related to drug use.[5]

Protection of narcotics addicts and abusers is achieved with the promulgation of Act No. 35 of 2009 concerning Narcotics. The Narcotics Act adheres to the *Double Track System*, which is a criminal law policy in the formulation of the provisions governing sanctions given to narcotics abuse offenders, namely in the form of criminal sanctions and sanctions for acts considering that narcotics abusers have a slightly different position from other. One side of the narcotics user is a criminal offender who must be punished, but on the other hand is a victim of a criminal offense he committed himself, so an action in the form of rehabilitation is necessary.[6]

The National Narcotics Agency of South Sulawesi Province noted the number of drug users and illegal drugs in South Sulawesi are still quite high. So that with rehabilitation as an effort or the best way to save people from the drugs.[7] Rehabilitation of narcotics addicts is also a form of social protection that integrates narcotics addicts in a social order so that no longer commits drug abuse. However, as it turns out into practice, rehabilitation of abusers is considered unsuccessful.[8] Many cases of narcotics abuse experienced by Indonesian public figures are an example of the ineffectiveness of rehabilitation as one of the ways implemented in combating narcotics crimes. Where in some cases, the public figures that were decided by the judge undergoing rehabilitation even re-used. As if rehabilitation is only to stop the abuse of narcotics for a while and still less able to treat and make peoples to free from narcotics addiction.

In addition, because not a few of the abusers who are caught must lose their right to undergo rehabilitation as they should so the right to obtain access to essential health is not obtained especially for drug addicts, because the addict will be sentenced to prison. While it is common knowledge that prison is no longer a safe place from these illicit goods. Hence, rehabilitation sanctions should be *premium remidium* and imprisonment as *ultimumremidium* in the prevention and eradication of narcotics crime so that the narcotics circle can be broken down to its roots.

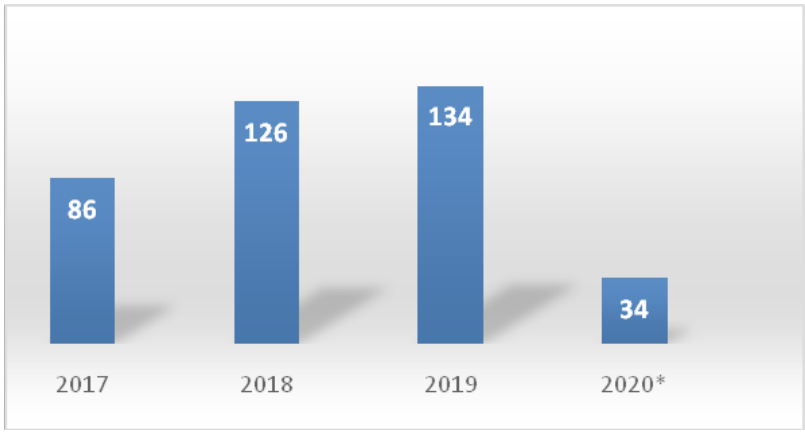
Method

The research is a normative legal research using a statute, case, and conceptual approaches.[9] The research location was centered on the National Narcotics Agency of South Sulawesi Province and the District Narcotics Agency. In this research, we uses direct interviews with narcotics abusers, the parties to the National Narcotics Agency, the parties to the Provincial National Narcotics Agency and the rehabilitation institutions.

The Essence of Medical Rehabilitation Sanction Imposing against Narcotics Abuse Victims: At this time, inevitably that the development of narcotics use is increasing rapidly and not for medicinal purposes or scientific development, but to gain large profits, namely by conducting illegal drug trafficking in various countries.[10] This raises concern for the international community, given the impact caused by the misuse of narcotics which is very dangerous for the life of the nation and country, especially for the continued growth and development of the younger generation. Based on these considerations, several international conventions have been issued to deal with the development of the illegal narcotics trade.

Prevention of narcotics abuse is intended to fortify the public so as not to get involved in narcotics abuse, the target is people who have never been involved with narcotics abuse so as not to become abusers and not to become dealers.[11] Rehabilitation of narcotics abusers and addicts to cures the conditions of narcotics dependence against abusers and addicts so that the abusers and addicts recover from addiction/narcotics dependence. Abusers are prohibited and threatened with prison sentences as well as narcotics addicts who do not report themselves to recover are also threatened with criminal penalties, but forced efforts and punishment in the form of rehabilitation.

The phase of assessment at the Institution of Compulsory Reporting as described in the table is a phase that is general in nature and applies to all addicts and victims of narcotics abusers. This stage is also in accordance with what is regulated in Government Regulation No. 25 of 2011 concerning the implementation of the Compulsory Reporting on Narcotics Addicts. According to the author, this phase is still incomplete if it only reaches the rehabilitation phase. It is better to avoid the relapse of addicts and victims of narcotics abusers that there must be progress monitoring after following the rehabilitation phase to monitor the situation of the former addict. As for the number of addicts and victims of narcotics abuse that run the compulsory reporting at the research location, can be seen in Chart 1.



Source: Primary data, edited (March 16, 2020).

Chart 1. Number of addicts and victims of narcotics abuse to compulsory reporting at BNNK Watampone, South Sulawesi, Indonesia. (*Updates for January - March)

Based on the result of interview with Mrs. Eni as the Division Head of Rehabilitation of BNNK Bone as place to receive the compulsory reporting, as the result of reporting, it will be processed by conducting an assessment to determine the condition of the addict. Accordingly, the intended assessment includes:

a. Interview is to find out the medical history of addicts, the extent of narcotics use, the psychological state, the social background and to explore whether there is involvement with the network.

b. Observation is to see the behavior of addicts, whether there are things that are hidden.

c. Physical examination is to find out the vital signs in the body of an addict.

As result of assessment can be seen whether the addict has a connection with the network. If an indication of involvement with the network is found then this will be a reference for the Sub-Section of BNNK Bone for immediate action. Regarding the identity of the addict who is obliged to report will be guaranteed confidentiality. As a consequence, if not obey the rule of this compulsory reporting, the parents or guardians will be threatened with imprisonment as stipulated further in Article 128 of Act No. 35 of 2009 concerning narcotics.

Based on the narcotics laws, narcotics users can be seen from 2 (two) points of view. The first is the use of narcotics legally or in accordance with applicable legal requirements. The second is the use of narcotics illegally or contrary to the law referred to as narcotics abuse. Narcotics can be used legally and not against the law if it is done for medical purposes and scientific development. The Narcotics law also has two approaches to those who use narcotics illegally or against the law, or in other words misuse narcotics.

The first approach is to see narcotics users as victims so that they must be rehabilitated and the second is to see narcotic users as criminals. As in the explanation section of the narcotics law, it also regulates criminal sanctions for the abuse of narcotics precursors for narcotics manufacturing. To create a deterrent effect on the perpetrators of narcotics abuse and illicit trafficking of narcotics precursors, it is regulated regarding the imposition of criminal sanctions, both in the form of special minimum penalties, 20 (twenty years) imprisonment, life imprisonment, and capital punishment based on the group, type, size, and number of narcotics.

The policy in combating criminal acts of narcotics abuse is a positive legal policy which in essence is not merely the implementation of normative juridical laws. Besides the normative juridical approach, criminal law policy also requires a comprehensive and integral factual juridical approach. The law has provided sufficient legal umbrella and has regulated everything from suppliers, importers or producers to users, but at the level of implementation of law enforcement efforts still need to be improved. This is related to the performance of the legal apparatus itself.

The policy of crime eradication through the making of criminal law is an integral part of the community

protection policy and is an integral part of social politics. Social politics can be interpreted as all rational efforts to achieve the welfare of society and at the same time include community protection. One function of the imposition of rehabilitation sanctions is to carry out extra countermeasures against the problem of narcotics abuse which resolves the problem from its roots, namely from abusers in this case is abusers for themselves, addicts and victims of narcotics abuse.

Legal reform on Medical Rehabilitation against Narcotics Abuse: Legal renewal is defined as a process of conducting review on various formulations of applicable laws and regulations, and to which are implemented a number of changes in order to achieve efficiency, fairness and also the opportunity to obtain justice according to applicable law. It is generally understood that the actual legal reform takes place, when the body of authority forms the law, namely the judiciary and the legislators, the government and the legislative authority in power or authority in a country take a number of steps (legal policy) which is required to test the applicable law.[12] The legal policy was made in the context of legal reform.

The criminal justice system is a system in a society to overcoming the problem of crime. This system is considered successful if the majority of public reports as crime victims can be resolved by bringing the perpetrators to court and convicted.[13] The components that work together in the system of sanctions imposing against victims of narcotics abusers are the police, prosecutors, courts, prisons, the National Narcotic Agency. The four components are expected to work together to form what is known as the "*integrated criminal justice system*".

Hence, to be able to guarantee abusers as perpetrators of narcotics misuse in accordance with the purpose of making the Act, the Narcotics Act contains or adheres to the rehabilitation justice system in addition to criminal justice. Therefore, the Narcotics Law adheres to the Double Track Criminal System. The dealer follows the criminal justice track while the abuser follows the rehabilitation justice track. The rehabilitation justice system is a judicial system in which sanctions out of criminal sanctions become rehabilitation sanctions with the purpose that the suspect is cured and does not become a further abuser.[14]

The justice system that has been in effect mostly focuses only on the criminal justice system. Where, the abusers are victims and not free from prison sentences. From those who undergone prison sentences, not a few are returning to abuse narcotics (*relapse*). As well with those who undergo rehabilitation either through legal step or compulsory reporting, not a few who return to abuse narcotics (*relapse*). For this reason, according to the author, the imposition of sanctions that have been there needs to be reformulated again, where in the narcotics justice system that has been adhering to a dual track system independently between criminal and rehabilitation can be cumulative. In the sense that the imposition of sanctions against abusers is given a double sanction namely rehabilitation and prison sanction altogether. Rehabilitation sanction were imposed by considering the position of the abuser as a victim who should have received special treatment (medical) in order to be able to eliminate detox which could trigger the return of relapse.

For this reason, there are several articles in Act No. 35 of 2009 concerning narcotics which should be reformulated so that it can be imposed on abusers so that the purpose of this law can be achieved optimally, such as the narcotics addicts and victims of narcotics abuse must undergo medical and social rehabilitation, this article only allows imposed on those who are addicted and those who are persuaded, tricked, deceived, forced and threatened with using narcotics. While, many of abusers who first used narcotics because they were persuaded and deceived, because it is difficult to prove that Article 54 cannot be imposed on him as a victim.

Conclusion

The essence of medical rehabilitation sanctions imposing against victims of narcotics abusers who adhere to the double track system which is oriented to criminal and action sanction. In order to realize a narcotics-free State, the implementation of medical rehabilitation sanction imposing must reflect philosophical, juridical and sociological values, while considers the legal development and needs of the community in implementing narcotics crime eradication. The ideal concept of medical rehabilitation sanctions imposing against on victims of narcotics abuse can be done by reformulating several articles in Act No. 35 of 2009 concerning Narcotics which should be reformulated so that it can be imposed on abusers so that the purpose of this law can be achieved optimally.

Abstract

Purpose: The aim of the study is to assess the prevalence of anxiety and depression among the urban Indian population during the period of national lockdown imposed by the government of India to combat the COVID-19 pandemic

Method: Total 278 participants were participated in an online, cross-sectional survey. Anxiety and depression was assessed. Gender, age, occupation and average time spent on gathering information on COVID-19 was assessed.

Results: less than 30 years of age and students showed higher prevalence of depression. Participants spending more than three hours on COVID-19 information showed that 18.2%, 42.4% and 37.9% were mildly, moderately and severely affected by anxiety symptoms, respectively and 19.7%, 47% and 24.2% were mildly, moderately and severely affected with depression. Further, more than three hours of time spent on COVID-19 showed strong association with mild, moderate and severe anxiety ($p<0.001$) as well as mild, moderate and severe depression ($p\leq0.01$).

Conclusions: Participants, less than 30 years of age and students were found more likely to have anxiety and depression symptoms. Participants who have been spending more than three hours on COVID-19 information were strongly affected with mild, moderate and severe anxiety as well as depression.

Introduction

World health organization (WHO) declared the novel coronavirus disease 2019 (COVID-19) a health emergency in January 2020 and declared it a pandemic in March 2020. On 02nd April 2020, the total number of confirmed cases of COVID-19 were estimated at 938,348 with 48,571 deaths around the world due to the disease(1). In India, the first confirmed case of COVID-19 was reported on 30 January 2020. The number of confirmed cases increased to 1027 by 29 February 2020 which further increased to 2192 confirmed cases by 02 April 2020 and the count is rapidly increasing(2).

Previous study has reported on mental health crisis in China due to COVID-19, and said a health emergency occurring due to an epidemic of an infectious disease can prompt unfavorable situations and lead to long

lasting psychological consequences[3]. Any epidemic or outbreak of infectious disease can have a wide range of psychiatric comorbidities like stress, panicattacks, fear, depression and anxiety[4–6]. In addition, quarantine has been associated with high stress levels, depression, irritability and insomnia[7,8]. An investigation concerning COVID-19 pandemic reported a rate of 20.8-34% anxiety and 17.3-18.1% depression among general population [10-12]. In India, a study conducted on the effect of pandemic of COVID-19 and resultant lockdown also suggestsa significant adverse effect on the mental status of the population [12].

Therefore, the aim of the present study is to explore the prevalence and potential factors associated with anxiety and depression during the initial 21 days of national lockdown, imposed due to the spread of COVID-19 pandemic, among the urban Indian population.

Materials and Method

Study Design and Participants: A cross-sectional survey was conducted to assess the immediate psychological response of anxiety and depression during the epidemic of COVID-19 by using snowball sampling. Ethical approval was obtained and the study was conducted in accordance with the Helsinki Declaration.

Out of total 294 respondents, response of 278 participants were included on the basis of inclusion and exclusion criteria. Inclusion criteria were Indian participants, both gender,above 18 years of age and able to understand the English language. Health-care workers, sanitation workers, security professionals and delivery professionals were excluded. An online consent was taken from each participant before they answered the questionnaire. The participation was completely voluntary and non-commercial.

Procedure: An online survey was done using the questionnaire developed through 'Google forms' with attached consent form. The web link was circulated through e-mails and social networking mediums. Participants were encouraged to circulate the survey. On clicking the web link, participants were auto directed to a page containing demographic information,average time spend on gathering information on COVID-19,followed by the Generalized Anxiety Disorder (GAD-7) questionnaire and Patient Health Questionnaire (PHQ-9). Data collection, initiated on 29th march 2020 and culminated on 2nd April 2020, that is, during the initial phase of national lockdown.

Demographic Characteristics: The variables of demographic data included gender (male and female), age(<30 years and ≥30 years), and occupation which was categorized into (a) public sector employees, (b) private sector employees,(c) students and (d) others

Average time spent on COVID-19 information everyday: This section questioned the participants on the average time they spent each day on electronic, print, and social media for gathering information on COVID-19. Average time spent to gather information on COVID-19 was divided into three categories: (a) less than one hour (<1 hour), (b) one to three hours(1-3 hours), and (c) more than three hours (>3 hours).

Generalized Anxiety: The GAD-7 questionnaire is a 7-item self-assessment scale developed to assess the defining symptoms of general anxiety disorder[13]. Items in the scale were rated on a 4-point Likert scale. According toGAD-7, a score ranging from 0-4, 5-9, 10-14 and 14-21 represents absent, mild, moderate and severe anxiety, respectively [13].

Depression: PHQ-9 is also a self-assessment tool for depression with a 4-point Likert scale. PHQ-9 scores ranging from 0-4, 5-9, 10-19 and 20-27 represent absent, mild, moderate and severe depression symptoms, respectively[14].

Statistical analysis: All statistical analyses were carried out using SPSS version 24. Descriptive statistics were calculated for demographic characteristics including gender, age, occupation and average time spent on COVID-19 information every day. Prevalence of generalized anxiety and depression was stratified according to above characteristics, and chi-square test was used to compare the differences in responses between different groups. Univariate and multivariate logistic regression were performed to explore potential factors associated with generalized anxiety and depression. Statistical significance was indicated if $p \leq 0.05$ and confidence interval was set at 95%. The scores of the GAD-7 and PHQ-9 were expressed in frequency.

Results

Absolute and frequency distribution of generalized anxiety and depression has been reported in Table 1 and 2.

Prevalence of Generalized Anxiety and Depression Stratified by Gender, Age, Occupation and Time Spent Gathering Information on COVID-19 Pandemic: Prevalence of generalized anxiety and depression is illustrated in Table 1 and Table 2, respectively. There was no statistical significant difference in the prevalence of anxiety between males and females, <30 years and ≥30 years, or the participants involved in different occupations. However,significant difference was in the prevalence of anxiety between participants who spent<1 hour, 1-3 hours and>3 hours of average time spent on gathering information on COVID 19 (p<0.001) Table 1.

There was no significant difference in the prevalence of depression between males and females. The prevalence of depression was significantly higher (p=0.015) in participants of <30 years than ≥30 years of age (Table 2). There was significant difference found in the prevalence of depression between participants belonging to different occupations groups (p=0.01). Students showed higher prevalence of depression than public and private sector employees (Table 2). Similarly, significant difference was found in the prevalence of depression between different time spent on COVID-19 (p<0.001). >3 hours of time spent showed higher prevalence of depression than 1-3 hours and <1 hours of time spent on COVID-19 (Table 2).

Factors Associated with Generalized Anxiety and Depression during COVID-19 Pandemic: Univariate and multivariate logistic regressions revealed that only average time spent on COVID-19 (p<0.001) showed significant association with the severity of generalized anxiety. >3 hours of time spent on COVID-19 showed strong association with mild (p<0.001), moderate (p<0.001) and severe (p<0.001) anxiety (Table 3). Also, multivariate logistic regression analysisshowed the significant association of students (p=0.04)with only mild anxiety during COVID-19 pandemic (Table3).

The univariate logistic regression analysis showed a significant association of age (p<0.04) and average time spent on COVID-19 (p<0.001) with severity of depression. Participants <30 years of age showed strong association with mild (p=0.008), moderate (p=0.03) and severe (p=0.04) depression (Table 4). Similarly, >3 hours of time spent on COVID-19 was found to have strong association with mild (p=0.01), moderate (p<0.001) and severe (p<0.001) depression (Table 4). Additionally, there was significant association of students with moderate depression (p=0.02) even after adjusting other factors (p = 0.01) (Table 4).

Table 1. Prevalence of generalize anxiety (GAD-7) stratified by gender, age, occupation and average time spent on COVID-19 in the participants.

Variables	Anxiety Absent	Anxiety Present			χ^2	p-value

Discussion

Results of present surveyindicated that 50% participants was affected with anxiety symptoms because of the COVID-19 outbreak and lockdown, out of which 27.3% have mild, 13.3% have moderate and 9.4% have severe symptoms of anxiety. Similarly, 61.2% participants experienced depression, out of which 27% reported mild, 25.2% reported moderate and 9% reported severe symptoms of depression.

The present study found equal prevalence of anxiety and depression symptoms in male and female. We found similar results as the study conducted in China [10], whereas, the study conducted in Italy and hardest hit areas of China showed that women are more anxious than men due to the COVID-19 pandemic[11,15]. An epidemic of any infectious disease leads to an increase in the prevalence of mental illness [9–11], due to fear or apprehension of getting infected[16]. In the same context, people also avoid seeking medical help in case of common symptoms of cold or flu (which has overlapping symptoms of COVID-19) fearing screening and a positive COVID-19 diagnosis results in social exclusion, unwanted public attention and the stigma attached with the disease.

Age and occupation have similar prevalence rate of severity of general anxiety,whereas, a different prevalence rate of severity of symptoms of depression (Table 1 and 2). Younger participants showed higher prevalence of moderate to severe anxiety (statistically not significant) and depression symptoms when compared to the participants aged more than or equal to 30 years. Huang et al. and Rossi et al. also found similar results[10,11]. However, Wang et al. analyzed various different age groups ranging from 12 to 60 years and found no difference between these groups [9]. Increased depressive symptoms might be due to social isolation, limitation of outdoor activities and avoidance behaviour to limit socialization. Younger population tends to be moresocially-interactive than the middle-age population[17], therefore, it might be stressful for them to sit at home during the lockdown. Also, poor coping strategies or immature defence mechanism among the younger population combined with the stressful situation may lead to maladaptive behaviour[18].

Our study also found that students are more prone to mild anxiety and moderate depression. Wang et al. also found the association of students with presence of anxiety and depression during the COVID-19 pandemic[9]. Increase in depression is due to uneasiness experienced of risk exposure to the virus and thoughts about family and friends contracting the virus or suspected of being infected by the virus[19].Our study recruited mostly under-graduate or post-graduate students from different universities. We believe that sudden implementation of virtual online classes at universities can resultin a negative mental effect due to unfamiliarity with online teaching methodologies. Uncertainty regarding duration of quarantine, frustration and boredom due to disruption of usual routine, loss of social networks and confinement within the four walls leads to a sense of isolation[20] which further leads to deteriorating mental health.

Our study also found that the severity of anxiety and depression symptoms depended upon the time spent on gathering information regarding COVID-19. We found that participants who spent >3 hours on COVID-19 information were strongly associated with mild, moderate or severe anxiety as well as depression. Roy et al. reported that the stress related to COVID-19 in India is mostly due to seeing COVID-19 related posts on social media, discussion on news channels and print mediaand rampant spread of rumors via social media platforms [12].They reported that the participants want to talk about the anxieties and stress related to COVID-19 with someone, but have to rely on electronic, social media and internet information which reduces the opportunities to de-stress. Also, media reporting about the shortage of resources and essential things for daily living further increasedpanic buying. As a result, people are not able to cope with the situation and feel emotionally exhausted.

Therefore few recommendations from this study are listed herein: First, limit the time spent on COVID-19 information to maximum one hour per day since excessive exposure to information. Second, minimize watching, reading or listening to news about COVID-19 and seeking information about the pandemic once or twice a day and it was further recommended that people should seek information only from trusted sources to get the true facts instead of rumors or misinformation[21]. Third, control over rumors, clear overview of authorities on the pandemic, health education and spread of knowledge of preventive measures could be implemented to reduce the negative mental impact of the pandemic.

This study had several limitations. The sample size is small which may limit the power of results. Snowball samplingtechniques resulted in self-selection biasness due to which an unbalanced occupation ratio

was seen. A major percentage(58%) of respondents were students. The study was conducted during the outbreak of COVID-19 in India, so participants' prior history of psychological state was not known and moreover, the anxiety and depression revealed in the study is self-reported and may not always clinically align with the diagnosis by mental health professionals. Future studies should be conductedduring different phases of lockdown including rural population. Further studies are required to monitor the impact of mental health outcomes in order to define mental health interventions for the general population level.

Conclusions

Participants with <30 years of age were found to be associated with mild, moderate and severe depression. Students were more likely to have mild anxiety and moderate depressive symptoms. Participants who were spending more than three hours on gatheringinformationon COVID-19 were strongly associated with mild, moderate and severe anxiety as well as depression.

Information Disclosure and Control on Online Social Network Sites among Medical Undergraduates

K. Sudha[1], Sangeetha A.[2], Kumaresan M.[3], Paarthasarathy B.[4]

[1]Associate Professor, Department of Anatomy, SRM Medical College, SRM Institute of Science and Technology, Potheri, Kattankulathur 603203, Chengalpattu District, Tamilnadu, India, [2]Assistant Professor, Department of Physiology, Saveetha Medical College and Hospitals, Thandalam, Chennai-602105, [3]Assistant Professor, Department of Anatomy, Saveetha Medical College and Hospitals, Thandalam, Chennai-602105, [4]IIMBBS, Department of Physiology, Saveetha Medical College and Hospitals, Thandalam, Chennai – 602105

Abstract

Introduction: Internet usage has become a big part of many people's lives, and among the many uses Social Networking Sites (SNS) which became very prevalent. How privacy concerns, trust and control are affecting SNS usage and self-disclosure has become an important question for many people.

Aim: Aim of the study is to assess the information disclosure and control on online social network sites among medical undergraduates.

Methodology: The study was conducted at Saveetha medical college and hospital among medical undergraduates. A questionnaire on usage of online social networks and information disclosures was administered and analysed it for reliability, social network site usage, privacy concerns, and disclosure of autobiographical memories.

Result: Almost 81.1% of the people feel that their browsing history were tracked by social networking sites. Instagram is mainly used app by medical undergraduates (40%).

Conclusion: There is an excess usage of social networking sites and easy information disclosure is seen in the population.

Keywords: *Social networking sites, information disclosure, online*

Introduction

Internet usage has become an integral part of many people's daily lives. The uses are abundant: jobs, research, games, starting new relationships, maintaining old relationships, etc. Social networking sites are a prevalent use of the internet. According to a survey conducted by Pew Research Center, roughly 85% of American adults use the internet and of these users about 67% use social networking sites[(1)]. Social networking sites have many benefits including allowing individuals to maintain contact without having to meet face to face, which allows people to maintain old relationships and start new relationships without having to meet in person with these other people. On the other hand, there are also possible problems associated with social networking sites, such as breaches of privacy.

Privacy is an individual's right to maintain editorial control and distributional control over personal information. Privacy is the right to determine how personal information is conveyed and who gets to know that information. There are privacy risks associated

with disclosing information that are affecting privacy concerns, even online. Privacy risks refer to one's personal information being accessed, used, or shared without any permission [3]. Identity theft and bullying are major online privacy risks. When it comes to sharing information on the internet, trust in others plays a central role. Online site trust is the expectation that one's vulnerabilities will not be taken advantage of in an online situation [2].

Control is another important aspect of internet usage. Control refers to one's perception that through one's own actions one is able to cause positive outcomes and avoid negative outcomes. Perception is very important for this variable. Although actual levels of control are not always increased, most social network sites are trying to increase the perception of control. An increased perception of control has been shown to correlate with decreased estimates of personal risk [3]. This evidence supports control having an effect on social network site usage and self-disclosure, because decreased levels of personal risk should correlate with increased social network site usage and self-disclosure.

Self-disclosure is an important topic of research in the area of computer-mediated communication. Self-disclosure is a broad category which includes any self-relevant information which one discloses about themselves, including autobiographical memories and future plans. Autobiographical memories are memories for personal life experiences. Autobiographical memories are especially important for research studies on relationships and the management of privacy online [4]. There are two main types of autobiographical memories [5]. The first type is general autobiographical memories and these are points of general self-knowledge [6]. The second type is specific autobiographical memories and these are specific episodes lasting for less than a day [6]. The study aims to understand the use of social networking sites by the under-graduate medical students.

Materials and Method

This study was conducted among a group (110) of medical undergraduate adolescents. Study participants were above 18 and below 23. The study was carried out after getting ethical committee approval (SMC/IEC/2018/11/337). In order to obtain the most accurate results, 50% (55) of the students have been selected through systematic random sampling method. Later, the survey method of research was applied to conduct the study and questionnaire was used as a data collection tool. The purpose of the research is to explain the information disclosure and usage of various social networking sites and to validate it more accurately; a questionnaire has been prepared and circulated among the adolescent medical students. Participants rated these self-report questions on a Likert-type scale from 1 to 5 (never to always or strongly disagree to strongly agree). The questionnaire also included self-report questions assessing general and specific autobiographical memory disclosures online (e.g. Will you share bank details through social media) also using a Likert-type scale from 1 to 5 (strongly disagree to strongly agree). These questions were compiled into the self-disclosure scale.

Results

Demographic distribution of respondents (N = 110). Majority (66%) of the population are willing to share their bank details only very rarely while a small fraction of 11.3% are willing to share it more often. Almost 81.1% of the people felt that their browsing history was tracked by social networking sites. Instagram is mainly used app by medical undergraduates. The next preferred app is facebook (50%) followed by snapchat. Majority of the people are willing to share to information online (66%) while (34%) are not willing to share their information online. About 71.7%of the participants feel safe in downloading stuff from unauthorised websites. A small proportion of 28.3%are not interested in it. A large number of the participants(50.9%)are downloading from unauthorised websites rarely while about 18.9%are downloading very often. Majority of the participants (56.6%) maintain anonymity in social media sites and about 43.4% are not doing so. Around 54.7% have the security software installed and about 45.3%donot have the required security software installed. About 77.4%of the participants are a victim of online frauds.

Around 81% of students were willing to share their residential address in the social networking sites. Only 18% of students were not willing to share. Fortunately, 66% of students were not willing to share the bank details and they want to keep it confidential. As stated above, only 22.4% of students were the victims of online banking frauds. Most of the students felt (81%) that their browsing history was tracked by social networking sites.

Discussion

Numerous studies have been conducted on social networking sites all over the world due to the exponential

use of social networking sites globally in recent years. According to a researcher, social networking sites have become the most heavily used websites, and they are ranked as one of the top sites visited globally[6]. These sites have become an integral part of the daily personal, social and business lives of many people [7]. The students at large have started to widely make use of social networking sites; however, few students have shown reservations. Few don't show interest, few others don't have time, few have privacy concerns while few don't have the facility and others think that it isn't beneficial to use social networking sites. The privacy is one of the obstacles in social networking highlighted by many scholars all over the world [8]. Facebook was the first social network to surpass 1 billion registered accounts and currently sits at 1.59 billion monthly active users. Eighth-ranked photo-sharing app Instagram had over 400 million monthly active accounts [9]. The present study clearly states that around 40% of medical students are using instagram as most common social networking site.

Social networking is everywhere today and is being used by people of all ages and for the widest variety of purposes [10]. Social networking tools are commonly used by individuals of all ages, but are used especially by young people and college students [11]. The demographic profile of social networking sites users varies, with junior and younger researchers more likely to be frequent users of social networking sites [12]. A study to assess the use of online social networking sites among the college students of a large urban university in Los Angeles has revealed that the students often used social networking sites to connect and reconnect with their friends and family members[13].

Conclusion

The results of this study examine many aspects related to the usage of SNSs by students; however, there are several areas that need to be addressed in future research. Further studies are needed to examine additional issues of SNSs such as legal, ethical and intellectual aspects. The potential risks of the research are minimal. Additionally, future studies can be conducted on academic use of SNSs in educational institutions.

Factors Related to Deaths Due to Suicides in Females Aged 12-24 Years

Kandagatla Krishnamurthy[1], Shruthi Reddy Jillella[2], Abhijith Subedhar[3]

[1]Tutor, Department of Forensic Medicine, Government Medical College, Nalgonda, Telangana, [2]Senior Resident, Department of Forensic Medicine, Gandhi Medical College, Secunderabad, Telangana, [3]Professor, Department of Forensic Medicine, Osmania Medical College, Hyderabad, Telangana

Abstract

Background: Suicide is a global health problem occurring in all parts of the world. It was the second leading cause of death among 15-29 year olds in 2016. Hence, an understanding of specific factors related to suicide would enable prevention strategies to be more sensitive.

Method: A cross sectional study was conducted in Department of Forensic Medicine, Gandhi Medical College, Secunderabad, which included all cases of suicidal deaths in females in the age group of 12-24 years in the period of January 2017 to November 2018.

Results: Majority cases belonged to the age group of 19-24 years (49%). Many victims were from rural area (60%), belonging to middle socioeconomic status (57%) and unmarried (80%). Majority of the victims were graduates i.e. 32% and 55% of them were students. The leading motive behind the suicides was emotional disturbances (21%). Hanging is the most commonly adopted method to commit suicide i.e. 53% of deaths.

Conclusions: Most of the factors related to suicide are preventable. Suicides among the young can be prevented by starting student guidance clinics and should also incorporate woman specific strategies like providing education, economic security and empowerment of women.

Keywords: *Suicides, females, adolescents, method of suicide, socio-economic factors.*

Introduction

Suicide is awillful and voluntary act of a person who understands the physical nature of the act, and intends by it to accomplish the result of self-destruction. It is the deliberate termination of one's existence, while in the possession and enjoyment of his mental faculties.[1] Suicidal behavior includes thinking about suicide (or Ideation), planning for suicide, attempting suicide and suicide itself. [2]

Suicide is a major public health problem all over the world. The world health organization (WHO) reports that every year more than 8,00,000 people die from suicide and it was the second leading cause of death among 15-29 year-olds globally in 2016.[2] The results of a 2012 Lancet study on death by suicide in India exposed a shocking trend of suicide among adolescents, which showed that a large proportion of suicidal deaths occurred between the ages of 15 years and 29 years, especially in women.[3] Adolescence is a stage of transition which needs mental capability, personality building and social adaptation. It has been observed that there is often a pressure to succeed over academics, relationship and self-identity during adolescence. Failure to overcome these challenges may lead to psychological distress and suicide.[4] A greater understanding of region-specific factors related to suicide would enable prevention strategies to be more culturally sensitive.[5]

The female suicidal behaviour in terms of total burden of morbidity and mortality combined is more in women than in men.[6] Women's greater vulnerability may be due to gender related vulnerability to various psychopathology and psychosocial stressors. Current data fails to accurately depict the major female contribution to this public health problem.[6] This study aims to identify the factors and precipitating causes that are responsible for suicidal deaths in females in 12-24 years age group.

Materials and Method

This was a cross sectional study done in the Department of Forensic Medicine Gandhi Medical College and Hospital, Secunderabad. The study included all cases of suicidal deaths in the age group of 12-24 years which were brought to mortuary for post mortem examination over a study period of 22 months (January 2017- November 2018). In cases where there was advanced decomposition and the cause of death could not be determined and in suspected poisoning cases where Chemical Analysis Report of Forensic Science Laboratory was negative, were excluded from the study. Socio-demographic variables and details about manner of death were obtained from reliable attendants of the deceased, hospital records, police records and inquest reports. Other details were obtained from the Post-mortem examination and Forensic Science Laboratory and Histopathologyreports. The family members, relatives and friends were fully explained about the questionnaire and then verbal consent was taken from each individual before asking about the relevant details pertaining to the study and thus a total of 100 cases were analysed. Data was analysed using SPSS software and descriptive analysis was done. Data are presented in the form of text, tables and figures.

Results

The Total study group has been divided into 3 sub-groups i.e., 12- 15 years, 16-18 years and 19-24 years. The highest number of cases were recorded in the age group of 19-24 group i.e. 49 cases (49%), followed by 16-18 years group which recorded 38 Cases (38%) and the least number of cases were seen in 12-15 age group with 13 Cases (13%). In this study, the highest number of cases were recorded in the Hindus i.e. 94 cases (94%) followed by, Muslims which recorded 6 Cases (6%).

Table 1: Socio-economic factors related to suicide

Factors		**Number of deaths**	**% of deaths**

	House Wife	13	13
	Laborer	9	9
	No Occupation	7	7
	Not Known	3	3

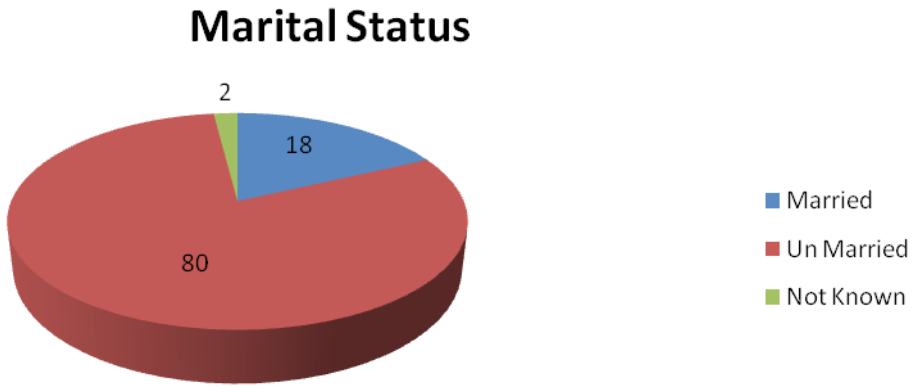

Fig 1: Marital status victims in deaths due to suicide in females aged 12-24 years

In this study group, 7(7%) cases of suicidal deaths occurred during menstruation. 1 (1%) victim who committed suicide was pregnant. In 92 (92%) of the cases, hormonal status of the victim was not known. According to the present study, in 24(24%)deaths, the motive behind the suicide was not known. In the remaining deaths, the leading motive behind the suicide was emotional disturbances amounting to 21 (21%) deaths. The other motives in the decreasing order of frequency were illness and love related issues sharing 13(13%) each, failure in exams and economic problems sharing same percentage i.e. 9(9%) each, marriage related issues i.e. 6(6%) of deaths, harassment for dowry i.e. 4(4%) deaths and the least motive behind the suicide was death of a family member i.e. 1(1%) of deaths.

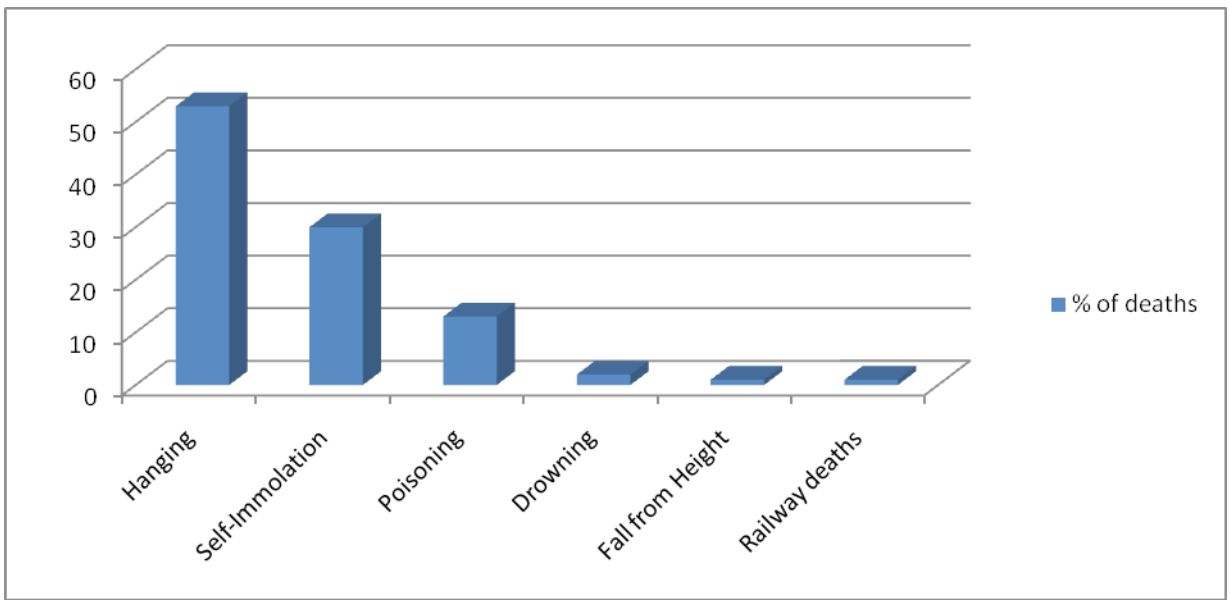

Fig 2: Cause of death due to suicide in females aged 12-24 years

Discussion

This study was conducted for over a period of 22 months in the mortuary of a Tertiary care centre i.e. Gandhi Medical College and Hospital, Secunderbad, Telangana, India.

According to the present study, the age group that constituted majority of deaths belonged to 19-24 years (49%) subgroup, similar to study conducted by Khan et alin 2005.[7] This was followed by 16-18 years age group which recorded 38% and the least number of cases

were seen in 12-15 age group i.e. 13%.Subjects from early study age groups (12-15 years) recorded deaths in lesser numbers. This may be due to unawareness of the suicide or submissiveness of the adolescent to their parents and society. Whereas it was more common in the late teenagers and young adults group (16-24 years), because of their short temperedness, social adjustment and hormonal surge issues, they became vulnerable for committing suicide. A study conducted by Aaron Ret al in southern India, concluded that youth is a period of increased risk of suicide and it is a leading cause of death among young people in India.[8]As per the study, suicides accounted for 75% of all deaths in young women.[8]A study by Omigbodun OO et al highlighted the role of media in providing information about various method of suicide among the youth.[9]In the present study, the highest number of cases were recorded in the Hindus i.e. 94 cases (94%) due to a higher percentage of Hindus in general population. Followed by, Muslims which recorded 6 Cases (6%). The findings were similar to study by Kanchan T et al conductedin 2008 at Manipal, Karnataka. [10]

There is a major impact of various socio-economic factors in the risk of suicides. As per this study, it is observed that the victims predominantly belonged to the Rural group i.e. 60 cases (60%), followed by Urban group which recorded 40 Cases (40%), which is similar to study conducted by Sachinanda et alin 2003, where majority of the victims also belonged to the rural background.[11] The higher incidence in rural areas is due to poverty, low education level, easy availability of poisonous substances like pesticides and lack of emergency care. In the current study, most of the deaths were noted in the Middle Class category accounting up to 57%, followed by Lower class category (40%) and least deaths were seen among the upper class category (1%) but study by Sachinanda et al, showed majority of cases belonged to a lower socio-economic class.[11] Majority of the deaths in middle and lower class population were due to lack of awareness and social stigma related with mental health disorders.

According to the present study, most deaths were noted in Graduates (32%) which is followed by Intermediate students (22%) and the least percentage of victims were seen in Illiterate category (9%). The findings are comparable to study that was conducted by Chavan et al in 2008, where majority of the cases were matriculates.[12] In the current study, majority of the deaths were noted among students (55%) followed by Employees & House wives, who were at the same rate i.e., 13%. In this study, the students were most vulnerable group to commit suicide as they were under pressure to excel in studies. Sexual challenges, emotional issues, low self-esteem or insecurities, family or financial problems and even substance addiction may play an important part.

A study by Owens SA et al stated that some phases in menstrual cycle are linked to suicidal risk, predominantly among hormone-sensitive women, such as those with premenstrual dysphoric disorder or premenstrual exacerbation of a psychiatric disorder.[13] In this study group, 7% of the suicides were committed during their menstruationphase. 1% suicidal deaths were seen in pregnant women. Majority of the deaths were seen among the unmarried women (80%) when compared to married women (18%), similar to studies by Chavan et al and Sarkar et al.[12,14] Unmarried and single women are usually more prone to depression.

The most common motives behind suicide as per study conducted by Bastia B.K. et al were marriage related issues followed by failure in examinations.[15] In the present study, in 24% of the death cases, the motive behind the suicide is not known. But, in the remaining deaths, the leading motive behind the suicide is emotional disturbances triggered by arguments at home, amounting to 21% deaths. The other motives were illness and love related issues, failure in exams, economic problems,marriage related issues, harassment for dowry and death of a close family member.

According to the current study, Hanging is the most commonly adopted method to commit suicide i.e. 53% of deaths. This is consistent with findings of other similar studies by Sachinanda et al, Chavan et al and Shaw et al,where hanging was the most common cause of suicidal death.[11,12,16] The other means adopted to commit suicide in the decreasing order of percentage of deaths are Self Immolation which constituted 30% of the deaths, 13% of the deaths were due to poisoning, 2% were due to drowning, and 1% each for fall from height and railway injuries.

Conclusion

Though suicide is a multi-factorial problem, most of these factors are either preventable or controllable. According to this study, students belonging to middle and lower socioeconomic status and residing in rural areas formed the most vulnerable group for suicides.

Suicides among the young can be prevented by setting up of student guidance clinics not only to improve their psychological well-being, but also to enable them to explore their own potential to engage themselves in today's world with immense avenues. The educational system must be changed to promote holistic development of the child, rather than giving undue emphasis on academic achievements alone. Various mental health training programs must be conducted periodically for the medical officers and paramedical personnel of district hospitals and primary health care centers especially in rural areas, so that they can be trained in early detection and preliminary management of mental illnesses.

Suicide prevention programmes should also incorporate woman specific strategies which include providing education, economic security and empowerment of women. Proper assessment of the symptoms and prompt treatment for women suffering from physical illness and mood disorders should be done.

Method of Ventral Hernia Repair: Our Experience

Ketul Shah[1], Ankur Jain[2], Vipul Gurjar[3], Anant Shah[3]

[1]Assistant Professor, [2]PG Resident, [3]Professor, Department of General Surgery, Dhiraj General Hospital, Smt. B.K. Shah Medical Institute and Research Centre. Sumandeep Vidyspeeth Deemed to be University (An Institution), Pipariya, Vadodara

Abstract

Background: Ventral hernias result from weakness in the musculofascial layer of the anterior abdominal wall. Ventral hernia can be operated through open or laparoscopic approach. Moreover, there are various options available for mesh placement during the repair. We here report our experience in surgical management of ventral hernias along with review of published literature along with laparoscopic repair of ventral hernias.

Method: It was a retrospective study of patients who were operated for ventral hernias over a period of 4 years in a teaching hospital of Vadodara SBKS research institute Dhiraj Hospital. All patients irrespective of age and sex were included. All patients were evaluated by obtaining proper history and performing detailed physical examination and routine blood investigations. Various intra operative and postoperative parameters were observed and reported.

Conclusions: The ventral hernia repair can be done by open and laparoscopic technique. Each has its own advantages and disadvantages. There is no conclusively guidelines about the superiority of one technique over the other and also no conclusively guidelines for the proper position of mesh placement. The clear advantages of open technique is avoidance of general anesthesia in many cases (as many ventral hernia repairs can be done under local anaesthesia), lesser learning curve, cheap meshes can be used, easy to learn, no requirement of any sophisticated instruments or OT setup and trained staff. The disadvantage of laparoscopic technique includes the requirement for general anaesthesia (as many ventral hernias can be performed with local anaesthesia in open technique), need to transverse the abdominal cavity, prolonged learning curves, requirement of costly meshes and sophisticated equipment and technical staff. However, laparoscopy has advantage over open hernia repair in terms of reduced postoperative pain, decreased postoperative complications, reduced length of hospital stays, less time for return to normal activity and bettercosmesis.

Keywords: *Hernia repair, Incisional hernia, Laparoscopic, Open, Ventral hernia.*

Introduction

Ventral hernia are happening because of shortcoming in the musculofascial layer of the foremost stomach divider[1]. The evaluated occurrence of ventral hernia is 15-20%[2]. They are grouped into incisional, umbilical, paraumbilical, epigastric and spigelian hernia [3, 4]. Most normal are incisional hernia after a stomach activity [5]. It is assessed that 2-10% of every single stomach activity result in incisional hernia[2]. Essential tissue fix should be possible in little hernias (<2.5 cms distance across). In any case, odds of repeat increments if essential tissue fix is accomplished for bigger hernias (> 2.5 cms in breadth). Thusly, the possibility of strain free fix utilizing prosthetic work is generally acknowledged. Prosthetic work has diminished repeat to irrelevant rates.[6].

For laparoscopic ventral hernia repair, the mesh

is routinely placed in the intra-peritoneal position. However, for open surgery, there are numerous options for mesh placement [7]. Only repair places the mesh on the anterior fascia which typically involves the dissection of flaps and primary closure of the fascia below the mesh. Inlay repair places the mesh in the hernia defect and secure the mesh circumferentially to the edges of the fascia. Sublay repair refers to retro- rectus preperitoneal mesh placement. Finally in underlay repair mesh is placed in intraperitoneal position and secured to the anterior abdominal wall, a technique popularized with the advent of laparoscopy [7].

The ideal position for placement of mesh has not been conclusively established [8, 9]. Polypropylene mesh is regarded as the implant of choice for repairing abdominal wall defects [8, 10]. Here we report our experience in surgical management of ventral hernias. We also reviewed our results with other studies, along with laparoscopic repair of ventral hernias.

Methodology

It was a retrospective study of patients who were operated for ventral hernias over a period of 2.5 years in a teaching hospital of vadodra SBKS research institute Dhiraj Hospital. All patients irrespective of age and sex were included. All patients were evaluated by obtaining proper history and performing detailed physical examination and routine blood investigations. All patients received antibiotic prophylaxis half an hour before surgery. Most patients were operated under spinal anesthesia. Foleys catheterization and nasogastric tube were occasionally used. Anatomical repair was done for smaller hernias (<2.5 cms in diameter) whereas mesh repair was done for larger hernias (>2.5 cms in diameter). In onlay repair, polypropylene mesh was sutured over the anterior rectus sheath, whereas in sublay technique, the mesh was placed in the preperitoneal space. The mesh was fixed with nonabsorbable sutures. Anterior rectus sheath was closed over the mesh by nonabsorbable sutures. Suction drain was placed based on the surgeon'schoice.

The patients were started on oral liquids 8 to 12 hours after the surgery in open mesh repair. Soft diet was started thereafter. Good analgesic coverage was provided with injection diclofenac/injection tramadol in early postoperative period which helped in early ambulation and recovery. Patients were encouraged for sitting up in the bed and advised early movements and activity. The wound was inspected for any seroma, hematoma, or infection. The drains were removed when the collection was less than 30 ml for 2 consecutive days. Patients were discharged after complete ambulation and tolerating normaldiet.

Results and Observations

The study included 95 patients with 46 males (48.4 2%) and 49 females (51. 58%) with male: female ratio of 1:1.07. The commonest type of hernias encountered were incisional hernias (76.84%), followed by paraumbilical (11. 58%), epigastric (8.42%), umbilical (3.16%) Table-1. The common index surgeries were gynecological and obstetrical surgeries

Table-1: Demographic parameters.

Variables	**Open ventral hernia repair (n=95)**
Mean age (range) in years	36.2(14-78) yrs
Gender Distribution	
Males	46(48.42%)
Females	49(51.58%)
Male : Female	1 : 1.07
Types of hernia	
Umbilical	3(3.16%)
Incisional	73(76.84%)
Epigastric	8(8.42%)
Paraumbilical	11(11.58%)
Total	**95(100%)**

Table 2: Index of Surgery

Index surgery	**No. of Patients**
Peptic perforation	11
Cholecystectomy (kocher's)	7
Enteric perforation	9
Tubercular perforation	9
Ruptured liver abscess	2
Prostatectomy	2
Pyelolithotomy	2
Appendectomy	7
Hysterectomy	10
Caesarean section	8
Post-tubectomy	4
Ovarian cystectomy	2
Total	**73**

The mean size of defect was 3.36 cm^2. The mean number of defects encountered were 1.4 (1-3). The content of most hernias was bowel loops (56. 84%), followed by omentum (43.16%). Anatomical repair was done in 18.95% of patients and mesh repair was done in 81.05% of patients. Polypropylene was used in all the cases. Onlay fixation was done in 67.53% and sublay in 32.4 7% patients. Suction drain was used in 85.2 6% patients. We met with single episode of accidental enterotomy (1.05%) while dissection which was primarily closed, mesh was placed & postoperative period was unremarkable. The average operative time was98.30 minutes in our study Table-3.

Table-3: Intra-operative parameters

Mean defect size	**3.36 cm^2**
No. of defects	1.4(1-3)
Contents of hernia	
Omentum	41(43.16%)
Bowelloops	54(56.84%)
Technique of repair	
Anatomical	18/95(18.95%)
Hernioplasty	77/95(81.05%)
Type of mesh used	Polypropylene
Site of mesh placement	
Onlay	52/77(67.53%)
sublay	25/77(32.47%)
Drain used (no. of patients)	81/95 (85.26%)
Intra-operative complications	
Enterotomy	1/95 (1.05%)
Operative time(in minutes)	98.30 min

Table-4: Post-operative parameters.

Mean Analgesia required (in terms of no. of times analgesic drug administered)	**6.4(2-10)**
Post-operative complications.	
Overall	23/95,(24.21%)
Superficial woundinfection	9/95,(9.47%)
Deep woundinfection	5/95,(5.26%)
Meshinfection	1/95,(1.05%)
Flap necrosis	1/95,(1.05%)
Seroma	7/95,(7.37%)
Mean Post-operative hospital stay (in days)	4.22 (1-18)

The average requirement of analgesia was 6.4 times in our study. Overall postoperative complication rate was 24.21%. Most of them were superficial wound infections (9.47%) and seroma formation (7.37%). All of which were managed conservatively. One of the patient developed mesh infection, but it was successfully managed with regular wound toileting with betadine, hydrogen peroxide and metrogyl-soaked gauze packing of the wound. The mean length of the post-operative hospital stay was 4.22 days (1-18 days) (table 4).

"The overall recurrence rate was 7.37% in our study at an average follow-up period of 12.02 months (3-28 months)". Anatomical repair showed more recurrence rate (22. 22%) than those with mesh hernioplasty (3.9%) Table-5.

Table-5: Follow-up and recurrences

Follow-up (in months)	**12.02(3-28 months)**
Recurrence rate	
Overall	7/95(7.37%)
Anatomicalrepair	4/18(22.22%)
Hernioplasty	3/77(3.90%)

Discussion

Ventral hernia in the anterior abdominal wall includes both spontaneous and most commonly, incisional hernia after an abdominal surgery[5]. Since the success of hernia repair surgery is usually reflected in terms of hernia recurrence after the repair, hernia recurrence is distressing to the patient and embarrassing to surgeons. The use of prosthetic mesh has revolutionized the field of hernia repair by providing tension free repair. More recently with introduction of laparoscopy in the field of surgery, the trend of laparoscopic ventral hernia repair is on rise. But with disadvantages of requirement for general anesthesia (as many ventral hernias can be performed with local anesthesia in open technique), need to transverse the abdominal cavity, prolonged learning curves, requirement of costly meshes and sophisticated equipment and technical staff makes laparoscopic hernia repair account for minority of cases performed

worldwide [11]. However, laparoscopy has advantage over open hernia repair in terms of reduced postoperative pain, decreased postoperative complications, reduced length of hospital stay, less time for return to normal activity and bettercosmesis[12].

The present study consisted of 95 patients, 46 males and 49 females with male: female ratio of 1:1.07. The commonest index surgery reported was gynaecological/ obstetrical operation. Most common site of ventral hernia was lower abdominal, again reflecting higher incidence of gynaecological obstetrical operation. The mean surgerytime in our study was 98.30 minutes, which is longer than that published in literature for laparoscopic ventral hernia repair surgery, which reflects the more time involved in dissection and securing haemostasis (95 minutes in Park *et al*.,[13], 87 minutes in Carbaja *et al*., [14], 56 minutes in Rameshaw *et al*.,[15], 55 minutes in Badiger S *et al.,*[16]. With respect to intraoperative complications, there was single episode of inadvent enterotomy while dissection which was primarily closed as it involved no spillage, mesh was placed and later postoperative period was uneventful.

The overall incidence of wound infection in our study was 24.21%. Since the amount of tissue dissection needed in open ventral hernia repair is more, the chances of wound related complications is more. Such complications are lower in laparoscopic ventral hernia repair as it does not need much of abdominal wall dissection. Most of the wound infections can be managed conservatively by local wound toilets and antibiotics. Removal of mesh is rarely required. For open mesh repair, the wound related complications range from 3.5%-18% [17-29], with an average of 8.1%; whereas for laparoscopic repair it is overall 2% [11,17].

The average number of times the analgesic drug administered in our study was 6.4. The literature [11, 17] reported a lower rate of requirement for analgesia in laparoscopic hernia repair than open technique as it involves lesser tissue dissection and avoidance of sutures as done in open ventral hernia repair. For the similar reason the early ambulation and hospital stay is prolonged in open ventral hernia repair then in laparoscopic repair.

Our study reported an average of 4.22 days as mean length of postoperative hospital stay for open ventral hernia repair. Syed JF Qadri *et al.*, [17] reported

1.53 days as mean hospital stay in laparoscopic incisional hernia repair group compared to 4.33 days in open hernia repair group. Similarly, Park *et al.*, [14] reported 3.4 days for laparoscopic repair group and 6.5 days for open hernia group; Rameshaw*et al*., [15] reported 1.7 days for laparoscopic repair group and 2.8 days for open hernia repair; and Badiger S *et al.*, [16] reported 2.6 days for laparoscopic repair group and 6.8 days for open repair group.

In various studies of open and laparoscopic incisional hernia repair, the recurrence rate reported is 0-12.5%.for.laparoscopic.repair,.with.an.average.of

5.97 %; and 0-13% for open technique,17 an average of 6.22 % [12]. Ramshaw *et al.*, reported a recurrence rate of 7% in open group and 0% in laparoscopic group at an average follow up for 21 months for each group. Pring*et al.*, reported a recurrence rate of 4.16 in open group and 3.3% in laparoscopic group at an average follow-up. period of 27.5 months for each group. Itani *et al.*, reported a recurrence rate of 8.2 % in open group and 12.5% in laparoscopic group at an average follow-up period of 24 months Thota *et al*., [12] reported a recurrence rate of 0% in both open and laparoscopic repair group at an average follow-up period of 13.25 months in open group and 10.5 5 months laparoscopicgroup.

Conclusion

Thus, in conclusion, the ventral hernia repair can be done by open and laparoscopic technique. Each has its own advantages and disadvantages. There is no conclusively guidelines about the superiority of one technique over the other and also no conclusively guidelines for the proper position of mesh placement. It was rightly mentioned in Author's previous article [11] that surgeons should not perform laparoscopic hernia procedure simply because it is relatively new or potentially economic; they should perform only when convinced that it is anatomically and physiologically correct and logical. Surgeons must be proficient in laparoscopic techniques and must have a precise knowledge of anatomy.

The advantages of open technique is to avoid of general anaesthesia in many cases (as many ventral hernia repairs could be done under local anaesthesia), lesser learning curve, cheap meshes can be used, easy to learn, no requirement of any sophisticated instruments or OT setup and trained staff. The disadvantage of laparoscopic technique includes the requirement for general anaesthesia (as many ventral hernias can be performed with local anaesthesia in open technique),

need to transverse the abdominal cavity, prolonged learning curves, requirement of costly meshes and sophisticated equipment and technical staff. However, laparoscopy has advantage over open hernia repair in terms of reduced postoperative pain, decreased postoperative complications, reduced length of hospital stay, less time for return to normal activity and better cosmesis.

Molecular Characterization of Sewage Bacteriophage and Their Efficiency in Treatment of Antibiotic Resistant Bacteria

Khalid Ibrahim Mahmood[1], Ahmed Mohammed Turki[2]

[1]Scholar Researcher, Ministry of Health, Anbar Health Office, Anbar, Iraq,
[2]Scholar Researcher, Biology Department, College of Science, University of Anbar, Iraq

Abstract

Background: The increasing prevalence of multi-drug resistant of bacteria strains, has become a global problem and therefore alternative method to antibiotics must be found. Bacteriophages are considered an alternative agent to control infection and contamination of the bacteria. **Method**: We used RAPD-PCR technique in present study, and used restriction endonuclease conformed presence unknown DNA fragments. **Results:** In this study, we described the isolation and character development of lytic bacteriophages capable of infecting bacteria specifically. Lytic bacteriophages, specific to *Escherichia coli, Klebsiella pneumonia, Salmonella typhi*, clinical strains, was first isolated from sewage. We have analyzed the DNA (RAPD)-PCR technique to produce unique and reproducible band from 21 different bacteriophages infecting *E.coli, K. pneumonia, S. typhi* . Used restriction endonuclease conformed presence unknown DNA fragments. **Conclusion:** Phages was capable of eliciting efficient lysis of studied bacteria, revealing its potential as a non-toxic sanitizer for controlling bacterial infection and contamination in both hospital and other public environments.

Keywords: *Bacteriophages, phage therapy, RAPD-PCR, Restriction endonuclease.*

Introduction

The discovery of antibiotics has revolutionized the treatment of infectious diseases, and because of their overuse, resistance to antibiotics has increased and has become a global problem that must be paid attention to, and to continue to follow the side effects of antibiotics, as at least (2) million people are infected with bacteria that are resistant to some antibiotics every year in The United States alone, and at least 23,000 patients die every year from infection[1]. The danger of these antibiotics do not distinguish or differentiate between beneficial bacteria and bacteria harmful to human. the misuse of these antibiotic enables bacteria to strengthen their resistance against these antibiotic, and they become stronger and more resistant to them[2]. Therefore, the scientists tended to phage therapy. Bacteriophages are viruses found naturally in the environment and have been studied to treat bacterial infections nearly 100 years ago. These phages invade and kill target bacteria by decomposition and do not attack mammalian cells. Phages are specialized for different bacteria. They bind to receptors on the bacterial cell walls to inject the phage DNA into the cell and eventually the cell lysis this in lytic phages[3] . During the lifecycle of the lysogenic bacteriophages, the DNA phage integrate into their host genome and evolve to coexist with bacteria. RAPD-PCR uses a randomized, purified DNA technique for extracted and purified DNA to help describe bacteriophages. RAPD-PCR is also used to assess the genetic diversity of phages[4].

The RAPD reaction is a PCR technique that works to duplicate DNA segments that are unknown and random, using one short primer (8-12 nucleotides), and does not require any prior knowledge of the genome sequence. It also uses very low amounts of DNA, moreover, it is very sensitive, allowing the discovery of a variety of DNA

Scholar Researcher, Ministry of Health, Anbar Health Office, Anbar, Iraq
e-mail: khalidibrahim361@gmail.com

as well as mutations. This technique is widely applied in various fields of research (medicine, forensic science, genetically modified organisms, genetic diversity, taxonomy). In addition, the RAPD technique was also applied to detect genetic instability in tumors and DNA changes caused by toxic compounds in animals, bacteria, and plants [5].

The aim of study: Isolation of bacteriophages and study of their genetic content.

Materials and Method

Microbiological culture media and chemicals. The main microbiological culture media we used in this research were BHA (Oxoid,UK), BHI (Oxoid,UK), EMB agar (Oxoid, UK) MacConkey's agar (Oxoid,UK) and Blood agar (Oxoid,UK). The SM buffer [(Tris-HCL, 10 Mm & pH = 7.6;MgSO 4 7H 2 O, 10 Mm; NaCl, 100 Mm and gelatin solution 2%(w/v), 5mL; distilled water, up to 1000 mL] (Merck, Germany). The chemicals we used were Methyl red, SIM, Urea agar, TSI and Simmon's citrate agar that provided from (Syrbio/Syria(.

Sample Collection: Collected samples from various sources including wounds, burns, urine, stool, spinal fluid and blood, were collected under aseptic conditions from Al- Anbar hospitals during the period (September to December 2019). The bacterial samples were carried immediately to the laboratory complex, Microbiology Branch, College of Science, Anbar University, Anbar, Iraq at 4◦C.

Isolation of bacterial species and their characterization

Isolated bacterial strains and exanimated by the compact vitek2 automated method according [6] .

Antibiotic Sensitivity Test: Bacteria strains was subjected to antibiotic resistance evaluation against a set of antibiotic discs including: Tetracycline(TE;10µg), imipenem (IPM;10µg), Meropenem (MEM;10µg), Ciprofloxacin (CiP;10µg), Ceftriaxone(CRO;10µg), Piperacillen (PRL;100µg), Gentamicin (GN;10µg), Chloramphenicol (C;10µg), Trimethoprim(T;12.5µg), and Nitrofurantion(F;100µg) all from(Bio analyses/ Turkey). Antimicrobial sensitivity testing was performed for strains of *K. pneumoniae, E.coli* and *S. typhi* using the disk diffusion method in accordance with National Committee for Clinical Standards guidelines (Clinical and Laboratory Standards Institute, 2019). The antibiotics chosen are usually used for the treatment the multi-drug resistance of bacteria.

Enrichment and isolation of bacteriophages: To isolate bacteriophages, public wastewater of Al-Anbar, Iraq was used as a possible resource .A total of 10 mL of wastewater for 20 min at 3000 g was centrifuged, and the supernatant was filtered using a 0.45µL syringe filter. For the enrichment of bacteriophages, 100 µL overnight bacterial culture and 10 mL wastewater filtrates were applied to 40 mL of BHI flask and then incubated for 24 h at 37C at 120 rpm shaking pace. In the same conditions, 10mL of BHI broth flask was centrifuged and filtered after 24 h. Then for the next stage the supernatant was stored at 4◦C. In order to confirm the presence of phages, 10 µL of phage filtrate was dropped on BHA 's bacterial lawns and then incubated for 24 hours at 37◦C.[7] .

Plaques purification and bacteriophage tittering: Double-layer agar method was used to purify the isolated phages and determine the phage titer. Briefly, phage filtrate was diluted to 10^{-12} using SM buffer then mixed 100 µL of each dilution and 100 µL of overnight bacterial culture and added to 5mL of 45bhc molten BHA top agar (0.5% agar). Then the mixture vortexed and quickly overlaid with 1.5 % agar on BHA media plates. The plates were incubated for 24 h at 37°C and the plaques of bacteriophage were enumerated on each plate. This method was executed in triplicates [8] .

Phage DNA isolation: Phage DNA was extracted as described previously from 100 mL of purified phage stocks previously dialyzed against SM buffer [9].

Genomic fingerprinting by RAPD analysis: Random amplification of polymorphic DNA was carried out according to a modification of the method described previously (Johansson et al., 1995). Primers OPL5(50-ACGCAGGCAC-30) and RAPD5 (50-AACGCGCAAC-30) were assayed at concentration (8 mM). PCR reactions were performed using PureTaq TM Ready To-Go TM PCR Beads (GE Healthcare, Munich, Germany) adding 10ng of purified phage DNA. Reactions were supplemented with 3 mM magnesium oxalacetate and/or 5% v/v dimethyl sulfoxide (DMSO). PCR was performed in a thermocycler (Bio-Rad, Hercules) under the following thermal cycling conditions: one cycles at 94 1 C for180 s; 40 cycles at 94 1 C for 30 s,35 1 C for 45 s and 72 1 C for 30 s (the extension step was increased by 1 s for every new cycle); and a final step of 5 min at 72 1 C.

Results

The identity of bacteria strains was confirmed to be *E.coli,S.typhi* and *K.pneumoniae* by VITEK2 compact system . The antibiotic sensitivity of E.coli, S.typhi and K.pneumoniae isolate was tested using the disc diffusion method and the results showed that all bacteria isolate was sensitive to Meropenem, imipenem but resistant to Ciprofloxacin, Ceftriaxone, and Nitrofurantion .

In Fig.1,2 showed 50 water samples were collected from different sources and 21 isolates of Bacteriophages specific for 9 *S.typhi*, 7 *K.pneumoniae* and 5 *E.coli* bacteria were isolated .by spotted method on solid media and double layer agar method. And the liquid media method.

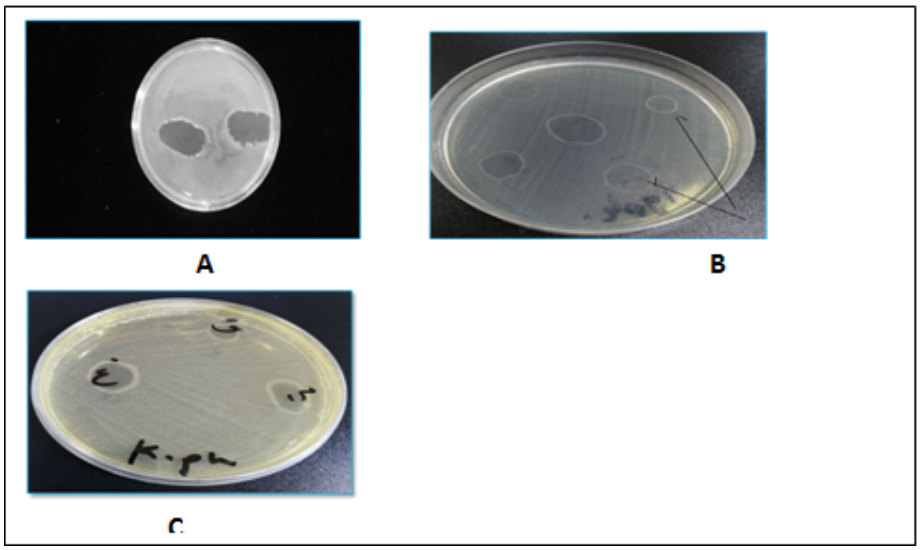

Figure 1. Plaque formation of (A) *E.coli*, (B) *S.typhi*, (C) *K.pneumonia* phages after 24h incubation at 37 °C on BHA

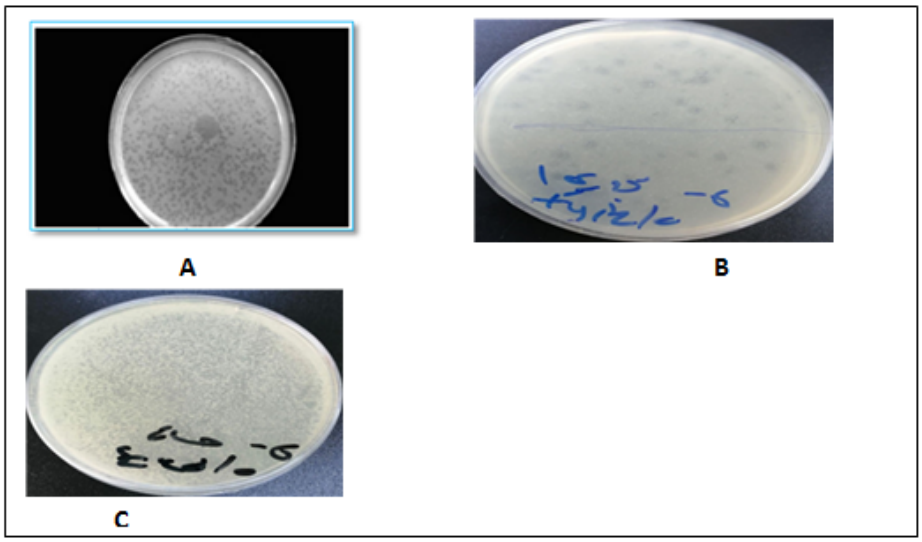

Figure 2. The total titer of (A) *K.pneumonia*, (B) *S.typhi*, (C) *E.coli* specific phages after 24h incubation at 37◦C on BHA.

Extraction genomic DNA: DNA was extracted for all selected bacteriophages with 21 phages, which were isolated from sewage from various sources. The extraction results highlights the presence of DNA bands for all studied phages . The integrity of the extracted DNA was confirmed after gel electrophoresis 1.5%. Fig. 3.

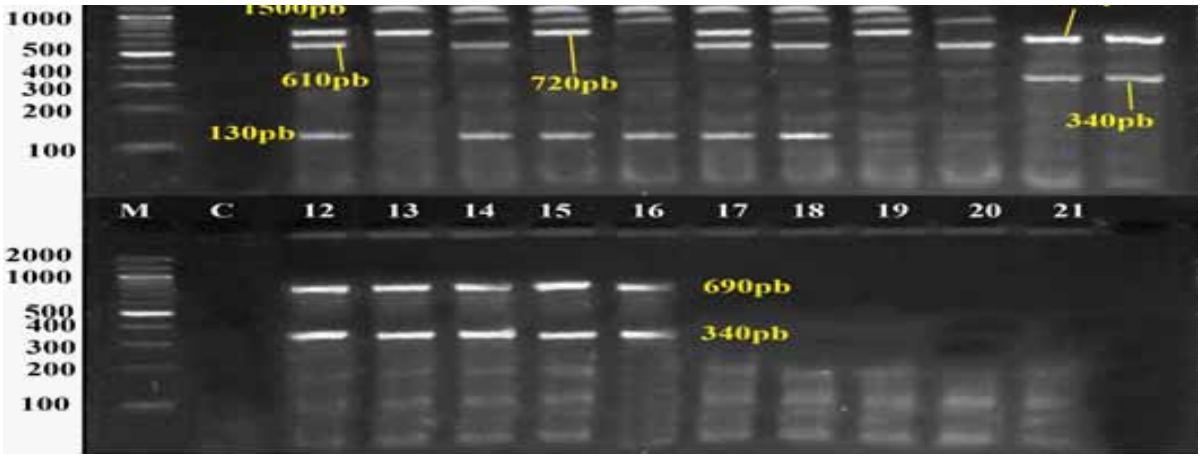

Figure 3. 21 Bands of genomic DNA and (M): DNA ladder (100 bp), agarose 1.5%, at 70 volt for 1 hr.

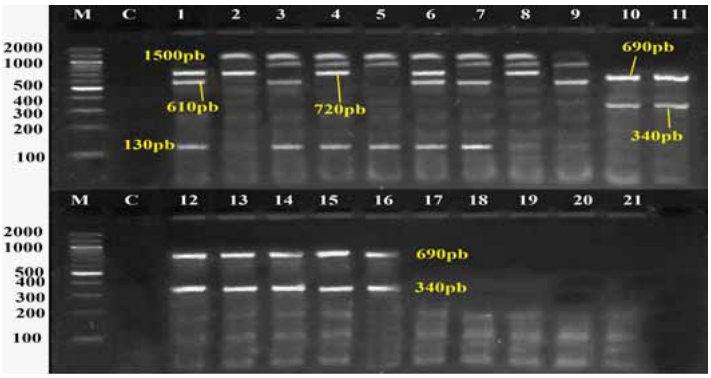
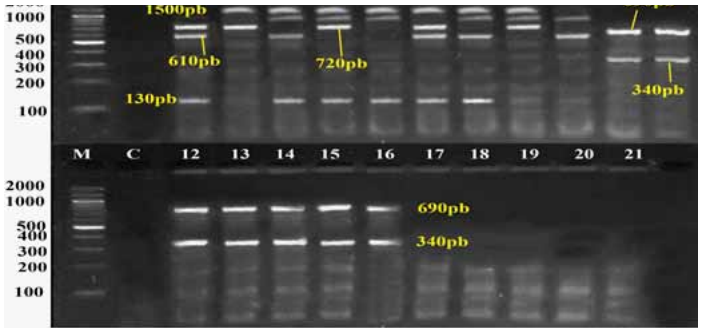
Random amplification of polymorphic DNA (RAPD-PCR) technique: Fig. 4 shows RAPD-PCR random amplification technique was performed using two primers OPL5, RAPD5 for all phages . This technique showed obvious difference in the number of DNA bands and a marked variation in their molecular weights according to the primer used. In Fig.4a, *S. typhi* phages (1-9) and *K. pneumonia* phages (10-16) showed positive results with OPL5 primer, while *E.coli* phages (17-21) showed negative results. But when using RAPD5 primer showed positive results of all the phages, Fig. 4b.



A



B

Figure 4. RAPD PCR products, Gel electrophoresis at 70 volt and 1h on 1.5% agarose gel showing [A] using OPL5 primer lanes positive of *S. typhi* phages(1-9), lanes positive *K.pneumonia* phages (10-16), negative lanes of *E.coli* phages(17-21). [B] using RAPD5 primer, lanes positive of *S. typhi* phages (1-9), lanes positive *K.pneumonia* phages (10-16), positive lanes of *E.coli* phages(17-21). Lane M: DNA ladder (100bp), C: negative control.

Restriction endonuclease enzymes: Four Restriction endonuclease enzymes (NdeI, SspI, Swa I, TaqI) were performed for all phages. The enzymes (Swa I, TaqI) did not produce positive result, while the enzymes (NdeI, SspI,) digested the DNA at more than one site and showed different bands and different weights as positive results. Fig5a, showed *S.typhi* phages(1-9) similar due to similar DNA bands and also similar all *E.coli* phages(17-21), while showed *K.pneumonia* phages (10-16) negative results with using NdeI enzyme. As shown Fig4b *S.typhi* phages(1-9) and *E.coli* phages(17-21) positive results, and negative results of *K.pneumonia* phages (10-16) after using SspI enzyme.

B

Figure 5. Restriction endonuclease products, Gel electrophoresis at 70 volt and 1h on1% agarose gel showing [A]using NdeI enzyme lanes positive of *S.typhi* phages(1-9), lanes negative *K.pneumonia* phages (10-16), positive lanes of *E.coli* phages(17-21). [B] using SspI enzyme, lanes positive of *S. typhi* phages (1-9), lanes negative *K.pneumonia* phages (10-16), positive lanes of *E.coli* phages (17-21). Lane M: DNA ladder (100bp). C: negative control.

Discussion

Increase of multidrug-resistant bacteria and other losses, supporting alternative therapy development. Phage therapy may be seen as an effective method for the prevention and control of bacterial infection [11] . The current study, the lytic and specific phages to the bacterial strains were isolated from different environmental sources; sewage was the main source; this finding is consistent with other studies[12].

The phages are the most abundant organisms in water, feces, soil and sewage water, therefore they are considered good indicators of bacteria presence[13].

RAPD-based method do not require sequence information when designing the PCR primers. We are therefore highly dependent on laboratory conditions such as DNA template concentration, PCR and electrophoretic environments, were selected to test several experimental conditions in order to produce reproducible RAPD patterns and gain a preliminary insight into the power of this approach to discrimination[14].

As shown in Fig. 4 OPL5, RAPD5 primer produced distinct amplicon band patterns . in current study Fig.4a shown S.typhi phages were different among them Whereas, *K.pneumonia* phages were similar these results are disagree with the researchers' findings [15]. The results shown in Fig.4b showed *S.typhi* phages (1-6) were similar after use RAPD5 primer in the RAPD-PCR technique . The phages of *S.typhi* (7,5,3) was similar too. *S.typhi* phages 4,8 differed from the other phages, The results of the current study are consistent with the findings [16] .

Fig.5a, Restriction endonuclease (NdeI, SspI) showed the enzyme's effectiveness in digesting the phage DNA fragments, SspI was more efficient and producing DNA bands. Enzymes can digest DNA at Recognition site or more than in the same strand. NdeI was digested of DNA in the same site and bands of the same molecular weight appeared for *S.typhi* phages lanes(1-9) and *E.coli* phages lanes (17-21), which means that the phages are similar. But *K.pneumonia* phages(10-16) was negative results with using NdeI enzyme, these results disagree with results [17] .

In Fig.5b Endonuclease SspI digesting the DNA phages of *S.typhi*(1-9) and *E.coli* phages(17-21) and produces different bands pattern,which means that the phages are different among them. These results are consistent with [18]. *K.pneumonia* phages(10-16) was negative results after digesting with SspI enzyme.

Conclusions

Phages characterization has shown that it has been very successful in lysing *E.coli, K.pneumonia, S.typhi*, it can be a good candidate for use as an alternative non-toxic green sanitizer. Host range research, however, revealed that phages did not infect other clinical strains of *E.coli, K.pneumonia, S.typhi* included in this review, indicating that more virulent bacteriophages unique to various bacterial strains will be screened and collected in the future. In potential phage applications a pool of lytic phages may be more effective against *E.coli, K.pneumonia, S.typhi* strains.

Abstract

A study was conducted to assess the awareness on covid-19 by using online platform among global community. The objectives were to assess the socio demographic characteristics, to determine the relationship between levels of awareness of COVID-19 with their selected demographic variables.

A global community based cross sectional study was conducted by internet survey design with 2857 respondents. Data were collected by online Google form, researcher administered a questionaries' awareness on COVID 19 through goggle link to the online platform and receive responses from the respondents,. The collected data was tabulated and analyzed. Descriptive and inferential statistics were used.

Researchers observed that 29.1% of the respondents reported high levels of awareness, 48.5% of the respondents reported moderate levels of awareness and 23.4% of the respondents reported low levels of awareness on COVID-19 respectively. It is very essential to create the awareness on COVID 19 among global population and protect the global community from deadly disease.

Keywords: *Cognizance, COVID-19, Online Platform, Global Community.*

Introduction

The coronavirus belongs to a family of viruses that may cause various symptoms such as pneumonia, fever, breathing difficulty, and lung infection[1]. These viruses are common in animals worldwide, but very few cases have been known to affect humans.

The World Health Organization (WHO) used the term 2019 novel corona virus to refer to a coronavirus that affected the lower respiratory tract of patients with pneumonia in Wuhan, China on 29 December 2019[2,3]. The WHO announced that the official name of the 2019 novel coronavirus is coronavirus disease (COVID-19)[4]. And the current reference name for the virus is severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2)[5].

However, current treatment on COVID-19 worldwide has mainly focused on infection control,

effective vaccine, and treatment cure rate (Dong et al. 2020; Wang et al. 2020), as countries worldwide have to work on reducing the transmission rate of COVID19 by creating awareness[6-9]. In this COVID-19 pandemic, timely access to accurate information can be the difference between life and death (UNICEF Ethiopia April 2020)[10].

As COVID-19 is a pandemic communicable disease, few things are known about the infection and from day today new updates and all what we heard about the infection to date are liable to updates/modification as the epidemiological study of the disease is underway**.** The basic awareness on COVID-19 among the Global community is acceptable. Timely dissemination of information by the Ministry of Health, WHO, UNICEF are very use full for the general public on the COVID-19. Here we are utilizing the online platform to assess the cognizance on COVID-19 IN Global community[6-10].

This study was conducted to determine the public response on Cognizance on COVID-19 by using online platform. This study surely helps the local, national and international organization to identify the awareness on COVID-19 and prevent further transmission

Objectives:

General Objective: The aim of this study is to assess the level of awarenesson COVID-19 by using online platform in Global community, 2020.

Specific Objectives:

1. To assess the respondents socio-demographic characteristics.
2. To determine the relationship between level of awareness of COVID-19with their selected demographic variables.

Materials and Method

Non-experimental evaluative approach was used.A community based cross sectional study internet survey design was adopted. The source population was all the stages of people across the global community during the study period. Person who satisfying the inclusion criteria such as age group 18 years and above were voluntarily participated in the study during the study period.

Sample Size Determination: The minimum sample size for online survey should be 100, required sample size was based on the estimated response rate, and at the time of proposal presentation tentative sample size was 2000 respondents.

Sampling Procedure: Received 2857 responses from various parts of country, respondents who were responded by using voluntary response sampling technique. All the stages of peoples across the world '26 different countries' were participated in the study.

Variables:

Dependent Variable:

- Awareness on COVID-19

Independent Variables:

- Socio-demographic factors

Data collection instrument and Questionnaires development

The questionnaire was prepared by the researchers, there were socio demographic questionnaire and 15 awareness questions on COVID-19 with the sources adopted from WHO, UNICEF and NHS. The questionnaire was translated from English into Afan Oromo and Amharic again translated back in to English, and comparisons were made on the consistency of the three versions.

Data Collection Procedure: Data was instinctively collected by using online platform. Respondents were filled the Google form for basic details voluntarily and also given the online consent to participate in the internet survey followed by respondents were filled the awareness questionnaire on COVID 19. Once who were successfully complete and submit the Google form instantly received their score by given email ID.

Data Processing and Analysis: Data was copied from Google spread sheet filled questionaries' were checked manually for completeness and then coded. Entered and cleaned using Epidata version 3.11. Double entry made to minimize entry error and exported to SPSS version 23.0 for analysis. Descriptive analysis was used to describe the percentages and number distributions of the respondents by socio-demographic and socio economic characteristics. Inferential statistics like 't' test and ANOVA test were used to analyze the data. P-Value< 0.05 was considered to be declared statistically significant.

Results

The cross sectional study internet survey was carried out to assess the awareness on COVID-19 among peoples from worldwide. The total of 2857 respondents was participated from 26 countries from the throughout the world as denoted in Figure-1.

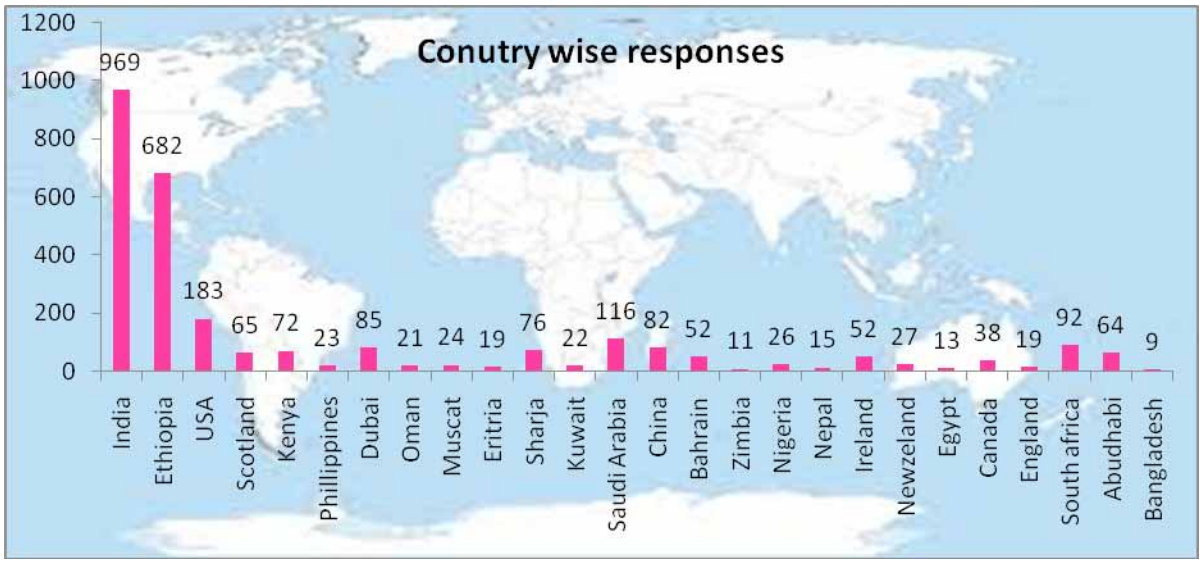

Figure-1: Country wise respondents on awareness on COVID19.

Socio demographic characteristics of the study respondents 1431 (50.05%) were belongs to 18-30 years, 756 (26.46%) belongs 40 31-40 years, 417 (14.60%) were 41-50 years and very few reporte in the age groups above 51 years as 253 (8.86%), in this 1236(43.26%) participants were male and 1621 (56.74%) belongs to female.

Significant difference between male and female with respect to awareness on COVID19 among the respondents were presented in Table 1 and it is revealed that significance difference between male and female of respondents. Based on means core, the female respondents (1.843) have high level of perception on awareness than male respondents (1.656). Field of education is presented in Table 2.

Table 1: t-test for significant difference between Male and Female with respect to Factors of awareness on COVID19 among the Respondents N=2857

Factors of perception on COVID19	Gender				t-value	P-value
	Male		Female			
	Mean	SD	Mean	SD		
Awareness	1.6569	0.7272	1.8435	0.7943	2.849	0.005*

Note:*Denotes significant at 5%level

Since P value is less than 0.05, null hypothesis is rejected at 5% level regard to Factors of awareness. Hence there is significance difference between male and female of respondents with regard to the Factors of awareness. Based on means core, the female respondents have high level of awareness on COVID 19 than male respondents.

Among 1236 (43.26) respondents were belongs to male, 1621 (56.74) respondents were belongs to female and their awareness on COVID 19 as follows: 832 (29.12), 1386 (48.51), 639 (22.36) low, moderate and high level of awareness respectively mentioned in Figure 2.

Figure-2: Percentage of level of awareness on COVID19 among the Respondents.

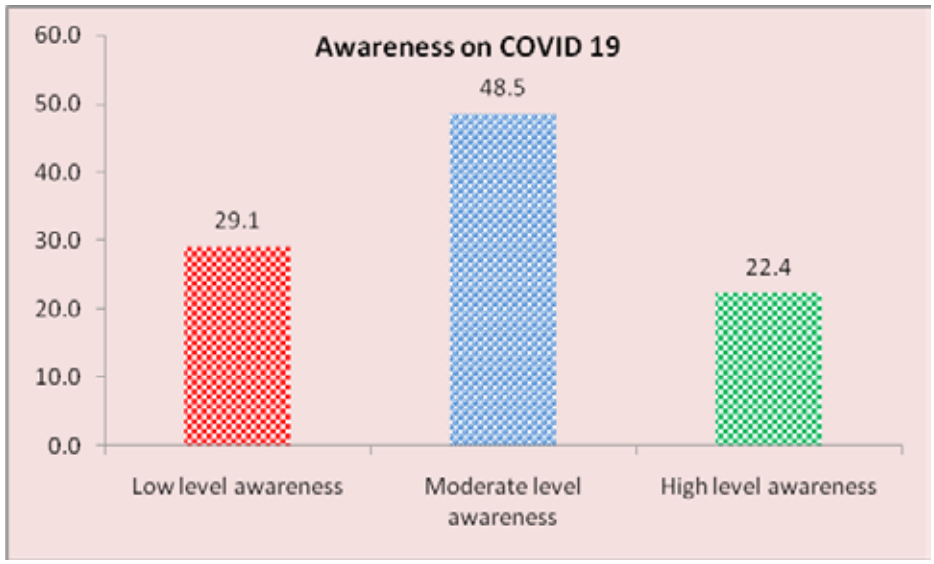

Table 2: ANOVA for significant difference among field of education with respect to Factors of awareness on COVID19 among Respondents

Perception on COVID19	Field of education		F value	P value
Awareness	Paramedical	1.98(0.78)	2.499	0.05*
	Arts and science	1.86(0.76)		
	Law	1.72(0.74)		
	Medical	1.82(0.76)		
	Engineering	1.79(0.74)		

Note: The value within bracket refers to SD, *denotes significant at 5%level

Table 3 Chi-square test for association between Gender and Level of awareness on COVID19 among respondents

Gender	Level of awareness			Total	Chi-square	P value
	Low	Moderate	High			
Male	356 (42.8) [28.8]	591 (42.6) [47.8]	281 (44.0) [22.7]	1236 (43.3) [100.0]	8.028	<0.005*
Female	476 (57.2) [29.4]	795 (57.4) [49.0]	350 (54.8) [21.6]	1621 (56.7) [100.0]		
Total	832 (29.1) [100]	1386 (48.5) [100]	639 (22.4) [100]	2857 100) [100]		

Note: The value within() refers to column Percentage, The value within [ ] refers to row Percentage, *Denotes significant at 5%level

Since P value is less than 0.05, the null hypothesis is rejected at 5% level of significance. Hence concluded that there is association between Gender and Level of perception of awareness on COVID 19 among the respondents. Based on row percentage, 28.8% of male have low level of awareness, and 22.7% of male have high level of awareness whereas for female 29.4% belongs to low level of awareness and 21.6% belongs

to high level of awareness. Hence majority of female respondents have high level of awareness and majority of males have low level of awareness as denoted in table 3.

Discussion

The study was aimed to assess the awareness of on COVID 19. It was supposed that, this study provided important information and created overall image on awareness on COVID 19 in global community.

Present online study with 2857 responses from 26 different countries, 969 (33.9) were from India, 682 (22.9) responses from Ethiopia and responses from others countries as follows: USA 183 (6.4) Scotland 65 (2.3) Kenya 72 (2.5) Philippines 23 (0.8) Dubai 85 (3.0) Oman 21 (0.7) Muscat 24 (0.8) Eretria 19 (0.7) Sharjah 76 (2.7) Kuwait 22 (0.8) Saudi Arabia 116 (4.1) China 82 (2.9) Bahrain 52 (1.8) Zambia 11 (0.4) Nigeria 26 (0.9) Nepal 15 (0.5) Ireland 52 (1.8) Newzeland 27 (0.9) Egypt 13 (0.5) Canada 38 (1.3) England 19 (0.7) South Africa 92 (3.2) Abu Dhabi 64 (2.2) Bangladesh 9 (0.3)

In this 1236 (43.26) respondents were belongs to male, 1621 (56.74) respondents were belongs to female and their awareness on COVID 19 as follows: 832 (29.12), 1386 (48.51), 639 (22.36) low, moderate and high level of awareness respectively.

Conclusion and Recommendations

As the researchers observed and concluded that the present study of awareness on COVID 19 among global community was most of respondents exhibited moderate level of awareness on COVID 19,few had high level awareness and around 30% of the respondents are reported low level awareness. So, need to create the awareness on COVID 19 throughout the world with the aim to reduce the spread of infection and also protect the global community from deadly disease.

Recommendations- Many Awareness program, Pamphlets on COVID 19 are created by the organizations like WHO and circulated. But it can be possible only by the common public, responsible persons should take initiatives in each country like ambassador's to spread the awareness to each and every individuals of the world. It is very essential and important to create the awareness on pandemic disease to protect the global population from the Coronavirus and to lead healthy life.

Acknowledgement: The authors wholeheartedly wish to thank the university heads, Dambi Dollo University, Oromia, Ethiopia for their support for completing the research and also extending the sincere acknowledgement to all the respondents from different part of the world.

Conflict of Interest: Nil

Source of Funding: The Corresponding Author received funding from the Dambi Dollo University for conducting the this global community research through online platform and obtained Permission for authorship and Publication of this article.

Ethical Clearance: Official ethical clearance letter was received from Research and Technology Innovative directorate office, Dambi Dollo University. After receiving the official letter from the University, seeking for the consent and voluntary response from the participants followed by they were recruited as study participant. Confidentiality, anonymity and privacy were maintained by excluding the name and ID of study participants from the questionnaire. Autonomous was maintained for recruited respondents. Justice was maintained by voluntary response to select all the participants and veracity also maintained by truthfulness in each stage of the study.

Abstract

A study was conducted to assess the level of stress, fear, anxiety and depression among adults in residing in selected area. The objectives were to assess the socio demographic characteristics of adults, to find out the association between level of Stress, fear, anxiety and depression of the respondents with selected demographic variables.

A community based cross sectional study was conducted with 634 adults were selected by the multistage random sampling technique. The data were collected by using standardized questionnaires, fear on COVID 19 and Stress, anxiety and depression on COVID 19. The collected data was tabulated and analyzed. Descriptive and inferential statistics were used.

Researchers observed that 35.5%, 4.1%, 13.2%, 8.2% of the respondents reported moderate levels of fear, stress, anxiety and depression respectively and 21.3%, 1.1%, 1.7%, 1.3% of the respondents reported extreme levels of fear, stress, anxiety and depression respectively.It is essential and in evitable to alleviate the stress, fear, anxiety and depression among general population and provide positive metal health.

Keywords: *Anxiety, COVID-19, Depression, Fear, Stress, South- Western Ethiopia.*

Introduction

Till date many studies were conducted on COVID-19 like knowledge, attitude, practice, studies but psychological aspects of COVID-19 studies are very less in numbers. Therefore, this study is aimed to assess the level of Stress, fear, anxiety and depression (SFAD) status of our community on COVID-19 to help the local and national planners to identify the gap in public response to develop a protocol to overcome the SFAD from pandemic outbreak[1].

One characteristic nature of infectious disease compared with other conditions is fear. Fear is directly associated with its transmission rate and medium (rapidly and invisibly) as well as its morbidity and mortality. This further leads to other psychosocial challenges including stigmatization, discrimination, and loss[2].

Morbidity and mortality statistics of Corona virus in 52 African countries are 13,600 and more infected cases, 742 deaths, recovered 2, 3583[-6]. Many of the ill people had contact with a seafood and animal market in Wuhan, a large city in eastern China, though it has since become clear that the virus can spread from person to person[7-10].

An individual's personality characteristics, genetics, and childhood experiences with major stressors and traumas may also dictate their response to stressors. Acute Respiratory Syndrome (SARS) and Middle East respiratory syndrome (MERS) coronaviruses. Susceptibility seems to be associated with age and other health conditions[8]. COVID-19 has now been declared as a Public Health Emergency of International Concern by the WHO[11, 12].

In a cross-sectional study, Wang et al(2020) evaluated psychological impacts, depression, stress, and anxiety at the beginning of the COVID-19 outbreak. In this study, 1210 participants from 194 cities in China answered an online questionnaire. The author showed that 53.8% of these people experienced severe psychological impacts of the outbreak. Moreover, 16.5%, 28.8%, and 8.1% of the respondents reported moderate to severe levels of depression, anxiety, and stress, respectively[13].

Objectives:

General Objective: The aim of this study is to assess the level of Stress, fear, anxiety and depression on COVID-19 in Kelem Wollega Zone, Oromia, 2020.

Specific Objectives:

- To assess the respondents socio-demographic characteristics
- To determine the relationship between level of Stress, fear, anxiety and depression of the respondents with their selected demographic variables.
- To correlate the level of Stress, fear, anxiety and depression of the urban and rural respondents with their selected demographic variables.

Materials and Method

Non-experimental evaluative approach was used. A community based cross sectional study design was adopted. The source population was all the adults living in Kelem Wollega Zone during the study period. Adults who satisfying the inclusion criteria such as age group between 21-50 years with a multistage random sampling technique participants were chosen for the study during the study period.

Sample Size Determination: The required sample size was calculated by using single population proportion formula and *open source Epidemiologic statistics for Public health*(version 3.01) assuming that 50% of the community is having **Stress, fear, anxiety and depression (SFAD)** on COVID-19.

$$n = \frac{(Z\alpha/2)^2 p(1-p)}{d^2}$$

where; n = sample size

P = by taking the calculated prevalence rate of 50%, Zα/2 = 95% confidence level which is (1.96), d = 5% marginal error, Sample size as per openepi and formula results as 384, Design effect is 1.5(384x 1.5=576) and after adding 10% none response, final sample size 634.

Sampling Procedure: In the first stage, three out of 12 woredas (25% of the total area) was selected by simple random sampling technique. In the second stage kebeles was selected from the woredas again using simple random sampling technique. In the third stage, a total of 634 households were selected using a systematic random sampling method. In this process sample was proportionally allocated to each selected kebele. Total number of households were obtained from the respective administrative areas and used to calculate the sampling fraction. Only one eligible individual was interviewed from the selected household. When two or more individuals are eligible in a household, only one was selected by lottery method.

Data collection instrument and Questionnaires development: The questionnaire was adapted from Structured standardized Five point likert Scale on Fear of COVID-19 (FCV 19S) and DASS Scale to assess the Depression, anxiety Stress on COVID-19 (2nd edition Sydney psychology foundation) were used by Structured Interview Schedule. The questionnaire was translated into Afan Oromo and again translated back in to English, and comparisons was made on the consistency of the two versions.

Data Collection Procedure: Data collectors were trained on the objective of the study and techniques of interviewing the participants. Totally 15 diploma holders midwives who were working in the area was deployed as data collectors on each selected kebeles. Data collection was conducted face to face interview

with structured questionnaire along with proper personal protective equipment. Respondent's doubts and queries also clarified by health workers. Supervisors followed the activities of data collectors daily and investigators guided the overall activities. Respondents were received pamphlets on coping tips to protect from covid-19 stress, fear, anxiety and depression.

Data Processing and Analysis: After the data was collected, filled questionaries' were checked manually for completeness and then coded. Entered and cleaned using Epidata version 3.11. Double entry made to minimize entry error and exported to SPSS version 23.0 for analysis. Descriptive statistics like frequency distribution, percentage, mean, standard deviation & inferential statistics like 't' test and fried man test were used to analyze the data. P- Value< 0.05 was considered to be declared statistically significant.

Results

The community based cross sectional study was carried out to assess the level of stress, fear, anxiety and depression on COVID-19 among study participants. The total of 634 participants participated in this study.

Socio demographic characteristics of the study participants were 238(37.5%) were belongs to 21-30 years. 177(27.9%) rural and 457(72.1%) were from urban, in this 420(66.2%) participants were male and 214(33.8%) belongs to female.

Significant difference between male and female with respect to Factors of fear, stress, anxiety and depression on COVID19 among the respondents were presented in Table 1 and it is revealed that significance difference between male and female of respondents with regard tot he Factors of fear. Based on means core, the male respondents (1.8429) have high level of perception on fear than female respondents (1.6589).

Table: 1: t-test for significant difference between Male and Female with respect to Factors of fear, stress, anxiety and depression on COVID19 among the Respondents

Factors of perception on COVID19	Gender				t value	P value
	Male		Female			
	Mean	SD	Mean	SD		
Fear	1.8429	0.7841	1.6589	0.7382	2.849	0.005*
Stress	1.2167	0.6008	1.2009	0.6293	0.307	0.759
Anxiety	1.5690	0.9879	1.4720	0.9770	1.174	0.241
Depression	1.4000	0.7889	1.3785	0.7701	0.327	0.744
Overall SFAD	6.0286	3.1617	5.7103	3.1146	4.657	**<0.001**** **<0.001****

Fried man test for significant difference among mean ranks towards factors of fear, stress, anxiety and depression on COVID19 among the respondents represented in Table: 2 and it concluded that there is significant difference among mean ranks towards Factors of SFAD. Based on mean rank, Fear (2.79) is the most important factor, followed by anxiety (2.52), Stress (2.37) and Depression(2.13).

Table: 2: Fried man test for significant difference among mean ranks towards Factors of fear, stress, anxiety and depression on COVID19 among the respondents

Factors of perception on COVID19	Mean Rank	Chi-Square value	P value
Fear	2.79	311.969	<0.001**
Stress	2.37		
Anxiety	2.52		
Depression	2.13		

Figure 1-4 presents perception of fear on covid19 among 634 participants 274 (43.2%) exhibits low level of fear and 135 (21.3%) exhibits high level of fear and perception of stress on covid19, 49 (7.7%) exhibits low level of stress and 07 (1.1%) exhibits high level of stress. Perception of anxiety on covid19, 50 (7.9%) exhibits low level of anxiety and 26 (4.1%) exhibits high level of anxiety and perception of depression on covid19, 93 (14.7%) exhibits low level of depression and 07(1.1%) exhibits high level of depression.

Figure: 1: perception of fear on COVID19 among the study respondents

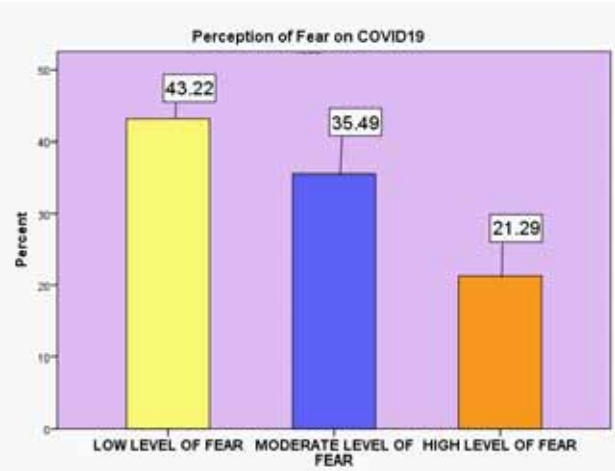

Figure: 2: perception of stress on COVID19 among the study respondents

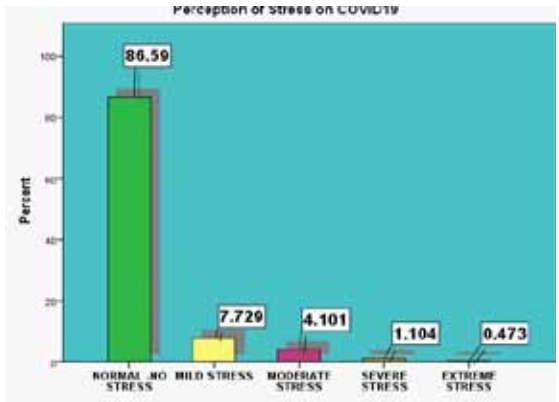

Figure: 3: perception of anxiety on COVID19 among the study respondents

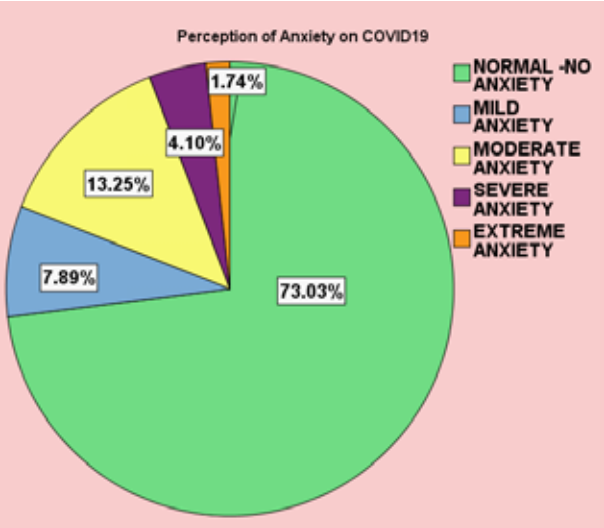

Figure: 4: perception of Depression on COVID19 among the study respondents

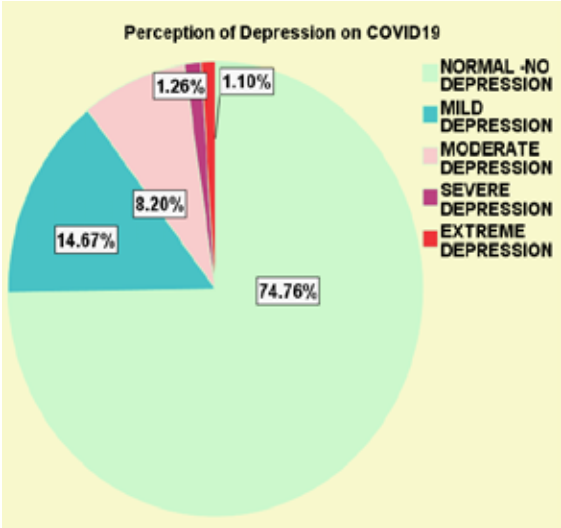

Discussion

Stress is a feeling of strain and pressure. It is a type of psychological pain. Small amounts of stress may be desired, beneficial, and even healthy. Positive stress helps improve athletic performance. It also plays a factor in motivation, adaptation, and reaction to the environment. Excessive amounts of stress, however, may lead to bodily harm. Stress can increase the risk of strokes, heart attacks, ulcers and mental illnesses. With the high levels Stress, fear, anxiety and depression (SFAD) of

individuals may not think clearly and rationally when reacting to COVID-19. However, current treatment on COVID-19 worldwide has mainly focused on infection control, effective vaccine, and treatment cure rate (Dong et al. 2020; Wang et al. 2020).

The study was aimed to assess the stress, fear, anxiety and depression on COVID 19 on kellemwollega zone. It was supposed that, this study provided important information and created overall image on stress, fear, anxiety and depression on COVID 19 in kellemwollega zone.

In a cross-sectional study, Wang et al (2020) evaluated psychological impacts, depression, stress, and anxiety at the beginning of the COVID-19 outbreak, 1210 participants from 194 cities in China answered an online questionnaire. The author showed that 53.8% of these people experienced severe psychological impacts of the outbreak. Moreover, 16.5%, 28.8%, and 8.1% of the respondents reported moderate to severe levels of depression, anxiety and stress, respectively[13].

On the other hand the researchers conducted the present study with 634 participants in different woredas 177(27.9%) rural and 457(72.1%) were from urban, in this 420(66.2%) participants were male and 214(33.8%) belongs to female and observed that 35.5%, 4.1%, 13.2%, 8.2% of the respondents reported moderate levels of fear, stress, anxiety and depression respectively and also observed that 21.3%, 1.1%, 1.7%, 1.3% of the respondents reported extreme levels of fear, stress, anxiety and depression respectively. In present study 3 woredas were participated from that one woreda is exhibiting high level of fear on COVID-19 110 (33%) comparing to all other woredas as follows: 10(6.7%), 15 (10%). These study results resembling the study results of other country.

Conclusion

Our study revealed that the majority of study participants had high level of fear, moderate level of stress and anxiety and very few showed that low level of depression. Researchers strongly recommending the Psychological first Aid training for health professionals and followed by psychological first aid to concern woreda respondents to help them to stabilize the mental health by reducing the fear on deadly pandemic disease COVID-19. It is essential and in evitable to alleviate the stress, fear, anxiety and depression among general population and provide positive metal health.

Acknowledgement: The authors wholeheartedly wish to thank Dr. Leta Tesfaye, President, Dr. Buli Yohanis Tasisa, Academic vice President, Prof. Yoseph Shiferaw Belayneh, Research and Community service vice President, Prof. Malkamu Tamiru, Research and Technology innovation Directorate Director, Dambi Dollo University, Oromia, Ethiopia for their support for completing the activities in a timely manner.

Conflict of Interest: Nil

Source of Funding: The Corresponding Author received funding from the Dambi Dollo University for conducting the research in 3 woredas and also obtained Permission for authorship and Publication of this article

Ethical Clearance: Official ethical clearance Letter was received from Research and Technology Innovative directorate office, Dambi Dollo University and it was presented to Kelem Wollega health department. All the information regarding the study, Researchers contact information, participants rights were provided in the first page of questionnaire. Written consent was obtained from each participant. Confidentiality, anonymity and privacy were maintained by excluding the name and ID of study participants from the questionnaire. Autonomous were maintained for both recruited & non recruited Participants by who are not willing to participate in the study was respected and they were not recruited in the study. All the enrolled participants were informed about the rights to withdraw from the study at any point of time. Justice was maintained by randomization to select the participants and veracity were maintained by truthfulness in each stage of the study.

Prevalence of Overweight and Obesity among School Going Adolescent in Patna

Kumari Mangalam[1], Chauhan Muneesh[2], Anand Akshay[3], Fatima Ambreen[1], Saho Pramod[1]

[1]Assistant Professor, Galgotias University, Greater Noida, [2]Student, Galgotias University, Greater Noida, [3]Assistant Professor, Manav Rachna International University, Faridabad

Abstract

Introduction: Now a day's Obesity has become pandemic concern globally and the prevention of later stage obesity will require elimination and management of childhood obesity. Childhood obesity and overweight are linked with hypertension, dyslipidemia and decreased metabolism of glucose that ultimately affects our quality of life and physical health and further can lead to increment in the risk of early disease and death.

Aims and Objectives: The current investigation was conducted to find out the prevalence of overweight and obesity in school going adolescents.

Material and Method: The present study was a cross-sectional, school-based study conducted in four urban schools of Patna from June, 2019 to, February 2020 with sample size of 660 adolescents (380 boys and 280 girls). The study design was approved by the institutional ethical committee. Three schools accepted our proposal out of 5 schools selected through systematic random sampling. A predesigned and pretested questionnaire was used to collect data on sociodemographic, dietary intake, physical activity and anthropometric measurements.

Result and Discussions: The pervasiveness of overweight and obesity was found to be 18.18%(120) and 10.9% (72), respectively in our study. The prevalence of overweight and obesity was 11.3% and 5.5%, respectively among the males. Males are more affectionate to Non Vegan-compared to females where the number of vegetarian supersedes the animal eater. Calories deficiency is 71.2% in the whole population on the other hand overeating was seen more in male candidates than females. More than 20% of the population was found to dine out once or more than once a week .Fast food intake found to be ingested in 44.6% population once or twice a week on the other hand there is a huge population of 37.8 % who are consuming 3-5 times a week. Mehta *et al*. revealed the predominance of obesity and overweight as 5.3% and 15.2%, respectively in his cross-sectional study which was directed in schools of Delhi. Sharma et al demonstrated that 6.4% school children are obese in Delhi.

Conclusions: The current study suggests that juvenile overweight and obesity is a issue of serious concern in urban community as well as all over. We can prevent this epidemic by doing lifestyle modifications and spreading awareness among people. To achieve this appropriate health education training and awareness program should be imparted to guardians, school authority and children.

Introduction

Presently, Obesity has become a serious and genuine unavoidable concern in all generation groups. Obesity is characterised as a condition wherein there is abnormal or uncurbed accumulation of fat in adipose tissue occurs, to the degree that health may be compromised[1]. This

worldwide pandemic of excessive weight and obesity -collectively termed as "globesity" - is quickly turning into a significant public health concern in all over the globe.

Obesity has outreached epidemic extent globally, and is a remarkable patron to the chronic ailment and disability having more than 1 billion adults overweight and around 300 million clinically obese[1]. progressively it is perceived as a critical issues in both developing and countries experiencing financial transition[2].

These issues are not only limited to adults but also being accounted among the children and adolescents of developed[3,4] as well as developing nations of the world[5]. This new drifting concern lead to various consequences in both adolescence[6] and adult life[7]especially increased rate of coronary artery diseases, hypertension, diabetes, dyslipidaemia[8], obstructive sleep apnoea[9], esophageal reflux & gastric emptying disturbances, osteoarthritis & flat feet[10], psychological dysfunction, self esteem & social isolation6, and overall increase in morbidity and mortality in later life[11].

Epidemiological studies have reported that about a third of preschool children and a half of school-age children become obese adults[12]. The effective prevention of adult obesity will require the prevention and management of childhood obesity[1]. India has also witnessed a gradual and continuous rise in trends of childhood and adolescent overweight and obesity[13]**.** Taking this into consideration of these realities, the present study was conducted to the prevalence of Overweight and Obesity in Adolescent School Children of "Patna", capital of Bihar.

Material and Method

The current study was a cross-sectional, school-based study conducted in four urban schools of Patna from June, 2019 to, February 2020 with sample size of 660 adolescents (380 boys and 280 girls) with the aims and objectives to determine the prevalence of overweight and obesity in adolescent school children. The study design was approved by the institutional ethical committee. In this study Three schools accepted our proposal out of 5 schools selected through systematic random sampling. Informed consent were taken from the parents prior to the study. Apparently Adolescents school children of Vth to Xth standard, in the range of 8-15 years of age were included in the study. Following Children having Chronic illness, Severe malnutrition, any type of Endocrinal problems, Physical & Mental disorders and Children with apparent obesity induced or associated with any syndrome were excluded from the study.

The data was collected by using the pre-structured questionnaire to assess total food intake, Type of diet, dietary habits, anthropometric measurement and physical activity.

Information on socio-demographic particulars, dietary habits and usual physical activity, time spent in watching TV and with computer and in other sedentary activities during the past one month, was assessed. Physical activity level (PAL) of the Children were assessed by using Global Physical Activity Questionnaire (GPAQ). Anthropometric measurements of weight (kg) and standing height (cm), waist circumference (cm), were taken by using standard equipment and procedures. Utilizing the weight and height, Body mass index (BMI) was calculated in Kg/m2, for each subject.

For overweight and obesity - IOTF classification was considered for calculation of overweight and obese subjects values between 85th -95th percentile were defined under overweight. values above 95th percentile were considered as obese subjects.

Result and Discussion

Ms Excel was used for Data entry. Statistical Analysis was done using SPSS version 22.0 software for Windows (SPSS Inc., Chicago, IL, USA) and $P < 0.05$ was considered as statistically significant. Descriptive statistics were calculated in the form of percentages, mean and standard deviation for the demographic data. A total of 660 adolescent school children were recruited. Out of 660 adolescents interviewed, 53.03(n=350) were males and 46.9% (n=310) were females. The pervasiveness of overweight and obesity was found to be 18.18%(120) and 10.9% (72), respectively in our study. The prevalence of overweight and obesity was 11.3% and 5.5%, respectively among the males.

Among the females, we found the prevalence of overweight was 7.2% and that of obesity was 5.4%. The prevalence of overweight and obesity was found to high among males.

Among the females, we found the prevalence of overweight was 7.2% and that of obesity was 5.4%. The prevalence was found to high among the males. Males are more affectionate to Non Vegan-compared to

females where the number of vegetarian supersedes the animal eater. Calories deficiency is 71.2% in the whole population on the other hand overeating was seen more in male candidates than females. More than 20% of the population was found to dine out once or more than once a week .Fast food intake found to be ingested in 44.6% population once or twice a week on the other hand there is a huge population of 37.8 % who are consuming 3-5 times a week. Only 36.3 % candidates were consuming fruits 5 times a week. Around 43% of Population in our study were performing moderate/vigorous activities remaining were performing the same activity level and they are 56% of the population. 50% of Population were performing moderate PA, while 28.4% were stuck on Low PA, Only 20.7% were performing High PA.13.3% of candidates uses mobile phone more than 2 hours a day while 42.7% of population still uses 1 hours every day. A major section of population doesn't uses computer i.e. 50.4% while 12.5% uses more than a hour.

Total sedentary time was 56.3% in 6-10 hours user. While 35.7% is the percentage of least user.

Discussion

India, considered as an ethnic group are mainly at greater risk for insulin resistance and central obesity, Prompting to diabetes, Heart Disease and other "life style" disorders. Over nutrition and sedentary lifestyle predisposes to various metabolic syndrome and type 2 DM. various investigations have demonstrated that these problems begins in childhood and manifest due to interactions and accumulation of multiple risk factors, throughout the life span. Mehta *et al*. revealed the predominance of obesity and overweight as 5.3% and 15.2%, respectively in his cross-sectional study which was directed in schools of Delhi[14].Sharma et al demonstrated that 6.4% school children are obese in Delhi[15].

In our study the event of overweight and obesity was found to be 18.18% and 10.9%, respectively. Perhaps this is on the ground that in Patna city there is accessibility of wide range of fast/junk food corners, modern electronic gadgets, games and transport facilities which are contributing for the increased prevalence of overweight and obesity in adolescents.

Similar finding were accounted by Goyal et al. with 12% of overweight and obesity among adolescents (aged 12-18 years) in addition to this It was also reported that the prevalence was higher in children who belongs to high socioeconomic class as compared to those who belongs to the lower socioeconomic class[16].

The predominance of overweight and obesity among the school-going adolescents of Patna was seen as high . Raj et al indicated a gradual increment pattern transition in health concerning with overweight and obesity[13]. Among all sedentary actions, TV viewing has received unique attention, and in this study, it was seen as to be a significant independent factor influencing overweight and obesity.

Overweight is characterized as a BMI between the 85th and 95th percentile for age and sex, and obesity−as a BMI greater than the 95th percentile. BMI is utilized as a particular pointer of abundance adiposity among children.

The prevalence rates of adolescents overweight and obesity in our region (Patna) were higher as compared to previously reported data from other areas in Bihar.

Conclusion and Recommendations

We Concluded that whether the city is enormous or small this is a genuine concern to be dealt with. It is very essential to take preventive measures such as awareness programs school based and community based to avoid this crucial issue of overweight and obesity. To sum up, our study also conclude that restricted physical movement, undisciplined and detrimental food tendency and increment in stationary and inactive way of life are turning out to be major contributing element for overweight and obesity. The current study suggests that juvenile overweight and obesity is a issue of serious concern in urban community as well as all over. We can prevent this epidemic by doing lifestyle modifications and spreading awareness among people. To achieve this appropriate health education training and awareness program should be imparted to guardians, school authority and children.

Limitations: For more vital and precise information larger sample size could have taken. however due to lockdown same could not be achieved. Information about the dietary habits, intake and others must be taken in front of guardian for accurate information.

Acknowledgment: We would like to thank all the participants of the study for their cooperation. **Financial support and sponsorship** Nil. **Conflicts of interest** There are no conflicts of interest.

Abstract

The paper investigates the relationship among social and demographic factors and a new case of spreading coronavirus in 24 countries over 88-day period from Jan 31, 2020 to April 27, 2020. This study collected second data from World Health Organisation (WHO)'s and World Bank's database, applied Co-integration test and Causality test for a panel data set.

The research provides crucial finding: there is causality between new cases of spreading coronavirus and time to close school too late. Moreover, Asian region, where the studied countries are being increases, new case of spreading coronavirus decrease. Furthermore, classification of income of the research countries is statistically insignificant to new case equivalent to absent association between the changes in the new case of spreading coronavirus and classification of income of the research countries.

The spreading COVID – 19 can happen everywhere from high income, middle income to low-income countries. Another finding is that late closing school will enhance spreading COVID – 19 goes more than one thousand cases.

Keywords: *COVID – 19, causality relationship and Asian region.*

Introduction

For years, people around the world have been facing many devastating disease relating to immunodeficiency syndrome such as HIV/AIDS, severe acute respiratory syndrome coronavirus SARS-COV and coronavirus (COVID – 19)... Wherever the epidemic strikes, human and society are affected. In December of 2019, some cases of unknown diseases are reported in Wuhan City, Hubei Province of China. From December 31, 2019 to January 3, 2020, there was 44 cases of patients with pneumonia of unknown etiology[1]. Until now, updated to 29 April 2020, in global scale, it is detected exceeded 3 million cases. Specifically, European and American regions are both reported with highest infectious cases: 1.4 million cases and 1.2 million cases respectively. With the urgent cases of COVID – 19, there are many studies investigate the impact and treatment of this virus. Researchers have found that COVID – 19 has the same origin with former SARS – COV, MERS, specifically R_o – refers to the basic reproductive number of new cases for SARS in the late 2000is in the range between

2 –5, that is resemble with the range of the mean R_o for COVID – 19[2]. These papers focus on the medical nature, origin of COVID – 19 and how to treat COVID – 19 medically. The outbreak of COVID – 19 is an urgent issue therefore the research tends to investigate the linkage among new cases of COVID – 19 and social, demographic factors. Our paper primarily aims to trace the relationship of new case of spreading coronavirus and social & demographic factors such as time to close school too late, classification of income in 24 countries in four areas including European, Asian, American and African regions from January 31, 2020 to 27 April, 2020.

Literature Review: Contact networks models likely refers to interpersonal contacts then easily lead to diffusion diseases in a community. Specifically, contact networks may happen within schools, workplaces, hospitals, households, therefore people in community can easily transmit the diseases if they are infectious. A group of previous authors generated a stimulated contact networks for the small city in Vancouver, British Columbia for the dataset approximately 1000 households equivalent to 2600 people[3]. In general, the contact networks model shows the crucial of contact patterns to the pandemic, especially, with different contact networks may share resemble the basic reproductive number of new cases($R_{o)}$, may have different epidemiological outbreaks results.

Regarding to medical geography, it is considered a spatial analystic method to evaluate the linkage between geographic determinant and illness people, in addition, can be used to identify the geographic processess affect pandemic dispersion. Traced back to the former cases to get involve in the sustantial role of spatial diffusion of deases, if we consider the impact of disease on global scale, the impacts of pandemic outbreaks in one part of the world will rapidly spread to the rest of the world. SARS outbreaks in Hong Kong and mainland China, then transmit rapidly to Toronto, the rest of the world. Gatrell[4]emphasized that diseases occur in specific location then by transportation or travel will enhance the diffusion. Whereby, group authorsidentified that if infectious people are barred at borders and if the Hong Kong as well as other continents did not leave their nation, there will not be a significant outcome as recognized until now[5].

At the beginning with the influenza pandemic, there is not available vaccine or antiviral medicine to treat diseases, therefore, social distance with a community is considered the vital method to protect itself. Some researchers indicated that this designed strategy is acknowledged effectively mitigate the diffusion of pandemic influenza without the use of vaccine[6]. Specifically, these authorsat the first stage described how social contact network-focused mitigation can be constructed, then a stimulation model for the influenza outbreak, hence, built a model in which there is a population of 10.000 of a small US town, the result showed that children and adolescents are subject of the flu therefore keeping them at home will reduce the attack rate (90%), moreover, with higher infectious strains, tailored to specific communities such as quarantine, closing schools, social contact network, working from home, etc. are suitable local defenses against pandemic in the absence of vaccine or antiviral medicine[6]. Gumel et al.[7] indicated that reducing the contact rate between susceptible and diseased individuals by isolating, is critical importance in order to reduce the diffusion of SARS.

With respect of temperature, the outbreaks of SARS in the 2000s and the spread of COVID – 19 recently are caused by impact of weather. However, there are few studies investigate relation between diseases with region and why diseases refer outbreaks in countries with low temperatures.A few researchers used ecological analysis to demonstrate the significant relation between daily numbers of SARS infected people with environmental temperature, whereby, temperature in the range 16 – 28 Celsius degree is likely associated with SARS cases, which may increase the virus growth. It is proved that during the outbreak of SARS in Guangzhou, Hong Kong, Beijing and Taiyuan, the temperature subsequently approximately from 16.5°C to 25°C[8].

Material and Methodology

The data was extracted from World Health Organisation (WHO)'s database for the new cases variable and World Bank database for three remain variables: Time to close school to late, Income and Region from 24 countries in European, American, African and Asian regions. The study collects the panel data with the long time series characteristic. There are four key variables:

- New case of spreading coronavirus (NEWCASE)
- Time to close school too late (TCSCH). This is a dummy variable (early close (closing Schools before March, 2000) = 0 and too late (closing from

1st March) = 1). This indicator represents the level of social distance of a country.

- Classification of income of the research countries (INCOME). This is dummy variable (high income = 1 and the other = 0), which shows the one of demographic variables.
- Region where the studied country are being (REG). This is dummy variable (Asian region = 1, the other region = 0). This vector confirms the different climate, cultural and society in cross-country.

The reason for choosing this period because although the disease appeared at Wuhan, Hubei, China ever since December 2019 but the disease pandemic started on global scale from January 2020 to April 2020. Furthermore, the research period provides evidence of the long-data for investigating causality link between COVID – 19 and social-demographic factors in long-term. Besides, the reason for selecting these 24 countries due to available data daily. The table 1 also notes that the panel data has outlier so the paper has to deal with this phenomenon.

The research applies four – step method to analyze the relationships of Coronavirus and social & demographic factors as follows:

First, due to outlier data so we check the Gini coefficient to ensure the equality value of the frequency distribution data. Owing to the outlier characteristic of NEWCASE (see table 1) so the research conducts the Gini coefficient correlation check that is appropriate with outlier phenomenon. Second, the research data is a panel with large T and small L, with outlier data so that we apply the Levin-Lin-Chu(LLC)[9] test (see table 3), which assumes that all panels have the same autoregressive parameter, that is, that rho_i = rho for all i. Then the alternative hypothesis is simply that rho < 1. The hypothesises (H) are that H_0: Panels contain unit roots and H_a: Panels are stationary. The LLC test requires that the panels be strongly balanced. Third, we apply the Westerlund and Edgerton[10] cointegration test with hypothesises that H_0: No cointegration and H_a: Some panels are cointegrated. Rejection of H_0 is thus substantial to validate an existence of co-integration given the entire the panel[10]. Finally, the study applies the causality test among all of the four variables to identify the direction of the relationship among COVID – 19 and other social factors following Ka and Mussard[11] for fixing outlier issue.

Results

Before conducting the main results, we carry out the descriptive and correlation analyses. Table 1 reports the results of descriptive statistics. There are 2112 observations during 88- days research period from January 31, 2020 to April 27 2020. The mean of NEWCASE is 989.70 cases while the standard deviation is too large. The new case of spreading coronavirus gets a peak when the United States of America was on the epidemic top of 38509 case in April 26, 2020.

Table 1: Description variables

Variables	Observation	Mean	Std. Dev.	Min	Max
New Case	2112	989.70	3675.29	0	38509 (United States of America April 26)
TCSCH	2112	0.52	0.50	0	1
Income	2112	0.58	0.49	0	1
REG	2112	0.58	0.49	0	1

Source: WHO and World Bank's database.

Table 2: Unit root test results

t-statistic	New Case		TCSCH		Income		REG	
	Statistic	p-value	Statistic	p-value	Statistic	p-value	Statistic	p-value
Unadjusted t	–8.37	0.00^{***}	–6.16	0.00^{***}	–7.08	0.39	–8.50	0.00^{***}
Adjusted t*	–4.46		–2.96		–0.29		–3.82	

Note: *t* statistics in parentheses: $^{*}p< 0.1$, $^{**}p< 0.05$, $^{***}p< 0.01$.

We check and know that the research data is a strongly balanced panel. The Gini coefficient correlation check shows that among independent variables (TCSCH, INCOME, REG) exist equality correlation excepts NEWCASE and among independent variable does not exist the correlation.

Table 2 confirms that almost variables stay, only variable "INCOME" is non-stationary. Next, we apply the co-integration test following the Westerlund and Edgerton[10] test to check the co-integration between dependent stationary variable and INCOME variable that does not stay. Table 3 below confirm the appearance of co-integration between these two variables. The results indicate that to reduce the new case of Coronavirus, the Government should focus on the effects of social factors: time to close the school, the high-income countries, and the area, whether the country belongs to.

Table 3: Results of cointegration test

	New Case – Income with outlier		New Case – Income without outlier	
	Statistic	**P-value**	**Statistic**	**P-value**
Variance ratio	1.51	0.07*	3.21	0.00***

Before running the causality test we check the outlier and get the results for exception of outlier during running regression for the lest bias later.

Having examined the long-run equilibrium relationship, we turn to the causality test among all considered variables, as shown in Table 4. The study conducts OLS and Gini regression with and without outlier to check robust of the model and get the results as seen as below.

Table 4: Results of causality

Variables	**Gini with outlier**		**OLS with outlier**		**Gini without outlier**		**OLS without outlier**	
	Coef Std. Err	**z P>z**	**Coef Std. Err**	**t P>|t|**	**Coef Std. Err**	**z P>z**	**Coef Std. Err**	**t P>|t**
TCSCH	1984.51 (151.02)	13.14 (0.00***)	2552.05 (139.55)	18.29 (0.00***)	1051.29 (51.33)	20.48 (0.00***)	1252.34 (49.53)	25.29 (0.00***)
Income	371.53 (180.53)	2.06 (0.04**)	332.34 (1048.08)	0.32 (0.75)	215.20 (60.78)	3.54 (0.00***)	203.10 (329.33)	0.62 (0.54)
REG	–1834.38 (182.13)	–10.07 (0.00***)	–1933.04 (1048.32)	–10.07 (0.07*)	–803.95 (61.85)	–13.00 (0.00***)	–834.75 (329.55)	–2.53 (0.01***)
Constant	805.68 (207.33)	3.89 (0.00***)	589.42 (1159.49)	0.51 (0.61)	353.70 (69.86)	5.06 (0.00***)	273.57 (364.43)	0.75 (0.45)
No. Obs.	2112		2112		2073		2073	
R^2/GR	0.80		0.13		0.75		0.24	
Gamma YYhat	0.73				0.76			
Gamma YhatY	0.58				0.57			
MSE			3429.3				1151.9	
Wald chi2			338.69 (0.00***)				647.07 (0.00***)	

Table 4 notes that both Gini and OLS regression with and without outlier points to the existence of direct effects on the new case of spreading coronavirus associated with time to close school too late. However, Gini regression also provides evidence of the positive effect of INCOME on the NEWCASE. This means the INCOME causes a new case of spreading coronavirus, the COVID – 19 has a positive link with the high-income countries. Besides,

their negative causality between REG and NEWCASE. The difference of region except ASIA will lead to a new case of spreading coronavirus. The model of Gini without outlier provides the better robust than OLS and Gini with outlier[11].All P-value and coefficients are statistically significant at 1% level except for INCOME variable. A positive coefficient of TCSCH indicates that the time to close school too late increases one day, the new case of spreading coronavirus goes up more than one thousand cases. Moreover, a negative coefficient of REG suggests that Asian region where the studied country are being increases, the new case of spreading corona virus decrease around eight hundred cases daily in Asia. This means the COVID – 19 pandemic is different across countries and social distance. Furthermore, INCOME is statistically insignificant to NEWCASE which means that there is no association between the changes in the new case of spreading coronavirus and classification of income of the research countries. Actually, the spreading COVID–19 can happen everywhere especially high income countries such as Italy, USA, Singapore or even low-income country such as Nepal. The result also supports and confirms the previous findings.[6,7]

Discussion

The pandemic COVID–19 virus outbreaks recently need to be discussed urgently for its effect on every society and economy globally. Applying both co-integration test and causality test, the research result indicates that there is a bi-directional causality between new cases of spreading coronavirus and time to close the schools too late as well as region where the studied country are being. Close schools are important factor to avoid infection and protect the young generation. Furthermore, with the studied countries, located in Asian region, the new cases of COVID – 19 can be easily down to around eight hundred cases daily. Next, the classification of income of the research countries is statistically insignificant tonew case of spreading coronavirus. Actually, from January 31, 2020 to April 27, 2020, the coronavirus has been spreading in global scale and in all classification of economics from high income to middle and low–income countries. Therefore, all governments should take highly consideration in social isolation in preventing the COVID – 19 in the absence of vaccine or antiviral medicine.

Source of Funding: The researchers do not get any research funding.

Conflict of Interest: We hereby confirm that the manuscript has no any actual or potential conflict of interest with any parties, including any financial, personal or other relationships with other people or organizations within three years of beginning the submitted work. Our paper has not been published previously, it is not under consideration for publication elsewhere.

Ethical Clearance: Taken research from secondary data through World Bank and WHO's database following the COPE's ethical committee.

Satisfaction and Complaints of Patients with Removable Partial Dentures: In Sample at Baghdad City, Iraq

Luma Musa Ibrahim

Assistant Lecturer, Ms.C. Prosthodontics, College of Dentistry, Alfarahidi University, Baghdad, Iraq

Abstract

Objective: This study examined patients' complain regarding pain on eating, esthetic and speech problems and gag reflex with various types of removable partial dentures (RPDs).

Method: The study sample included 60 RPD wearers (36 females and 24 males) aged between (25-60) years old. Sex, age, occupation, any experience with previous RPDs, and the complaint with RPDs were recorded. Data were analyzed using Chi-square test was applied for comparison among different variables of oral complaints related to removable prosthesis; an independent a sample *t*-test was utilized. A *P*-value < 0.01 was the criterion for rejection of the invalid hypothesis.

Results: the results show 60 patients, 16 (47.05%) were satisfied on acrylic and14 (77.77%) were satisfied on flexible. And 6 (75%) were satisfied on metallic. The mean level of satisfaction among the three types of RPDs was significantly different ($P < 0.01$). In cases satisfaction between flexible and acrylic RPDs was significantly different. But, between either metal or acrylic, or metal and flexible RPDs no significant differences ($P < 0.01$) were recognized.

Conclusions: Within the limitations of this study, approximately half of cases that tooka removable partial dentures treatment were satisfied with it, showing that the quality of RPDs(in Iraq/Baghdad city) was suitable for patients. Pain in eatingis the most common complaint that shows that dental treatments with RPDs should be provided with care when patients have pain in eating.

Keywords: *Patient satisfaction, Removable partial denture, oral complaint, Aesthetics, Dental prosthesis.*

Introduction

The missing tooth structure either caries attacks or injury or other pathological conditions makes researchers and scientists strive to find a suitable material or dental prosthesis to replace the tooth structure in terms of both function and esthetics[1]. This is because tooth loss has a negative consequence on facial appearance, speaking and masticatory function and still one of the major oral health problems in the world.[2,3]

Corresponding Author:
Luma Musa Ibrahim
Assistant lecturer, MsC Prosthodontics, College of Dentistry, Alfarahidi University, Baghdad, Iraq
e-mail: luma.musa@gmail.com

Now a day, there has been an increase in the number of patients who need prosthodontics treatments[4]. As a consequence, the demand for complete or partial dentures also has been raised. This is because of increasing the number of older people among the population as the result of rising life expectancy[5].Thus; there are various alternative treatment modalities available for replacement for partially edentate patients. These treatment involve prosthesis supported by implants, bridges supported by teeth, and removable partial dentures (RPDs)[6,7].

Therefore, choices, like as dental implants, can be not easy to apply because of general and/or patient preferences, oral limitations and financial issues.[8,9]

Many studies in different countries have found that the cost of treatments plays a crucial role during the construction of dental prosthesis for partially edentate

patients[10,11]. For these reasons, the removable partial denture is still the most common way of restoring the missing teeth[12,13].

A survey of 260 Iraqi volunteers based on 2018,whose loosing teeth had been effectively restored with RPDs, It is believed that the quality of prosthodontics treatments may affect significantly on quality of life related to oral health[14].

Despite easy construction, managing (RPDs), minimally invasive treatment choice, reasonably low cost but (RPDs) are still related to many oral complains such as mastication, speaking difficulties, pain and esthetic concerns[15]. The satisfaction of patients with a prosthesis therapy has become an increasingly significant factor in prosthetic treatment[16]. Thus, many studies have examined the relation between RPDs and cases satisfaction and their dentures quality[16,17]. It is believed that the quality of prosthodontic treatments may affect significantly on quality of life related to oral health[18,19].

It is not easy to expect the patient's satisfaction with RPDs therapy because it is a multifactor characteristic. It has been reported that patients' attitude towards RPDs, patient's personality, any contact with the previous RPD, patients believe the RPDs therapy or forced to do this treatment as well as denture design and fabrication procedures are related to RPDs satisfaction. In addition, there are other important factors, which are strongly correlated with RPDs acceptance by the patients such as, retention, stability, chewing ability and esthetics[20]. However, there is a gap in the information on patients' satisfaction and complaint among (RPDs) wearers in

Baghdad city, Iraq. This study aims to explore the patient's satisfaction with comfort or presence of pain, esthetic, retention, mastication, as well as speaking with RPDs.

Various bases have been progressed forma king RPD. Flexible,acrylic polymers (polymethyl methacrylate [PMMA]) and metallic (chrome cobalt alloys) materials. And due to the noticeably cheap, manipulated easily with utilization of low-pricetools, acrylic RPDs are the most accepted material for denture framework creation. Therefore, in flexibility term, nylon-derived denture base material make a revolution as a functional alternative material to overcome some restriction and came back to acrylic dentures.[21,22]

Correspondingly, in interview bytelephone with 260 Iraqi male and female cases who had got RPDs atCollege of dentistry/Baghdad University, college of dentistry/ Al-Anbar University and private clinics.

Even though RPDs are a reversible and a non-invasive therapy, with a suitable price and easy oral hygiene method in most cases, they are related to number of oral complaints, like speech problem, pain,mastication, as well as esthetic issues.[23,24,25] Therefore, this survey aimed to detect the complaints and satisfaction level among patients using the three types of RPDs in Baghdad/Iraq.

Materials and Method

This survey done at three places (College of dentistry/Baghdad University, College of dentistry/Al-Anbar University, private clinics)the dental data was searched for surveying(cases) participants the following criteria forcases included: the age group was(from 25 to 60), telephonic communication, complete and accurate dental data, and available therapy plan of action details. Cases with chronicdisorder or systemic diseases which could give an effect oral health, likeoral cancer and uncontrolled diabetes, were excluded.

All of 260 cases treated with RPDs from January 2018 to January 2019, these cases got interviewed by phone. 100 cases of them took a call. Of the 100, sixty cases (24 female and 36 male cases) agreed to be a participant in this study as seen in Figure 1. two questions were asked to each participant over the phone interview to detect their complaints and satisfaction levels of with RPD wearers, speaking, eatingas well as esthetics. The first question is "Do you have any complaints (comments)" The second question was: "how satisfied are you with the RPD?" cases (sex and age) and information on the type of RPD (acrylic,flexible, or metal) demographics were obtained from the cases dental data.

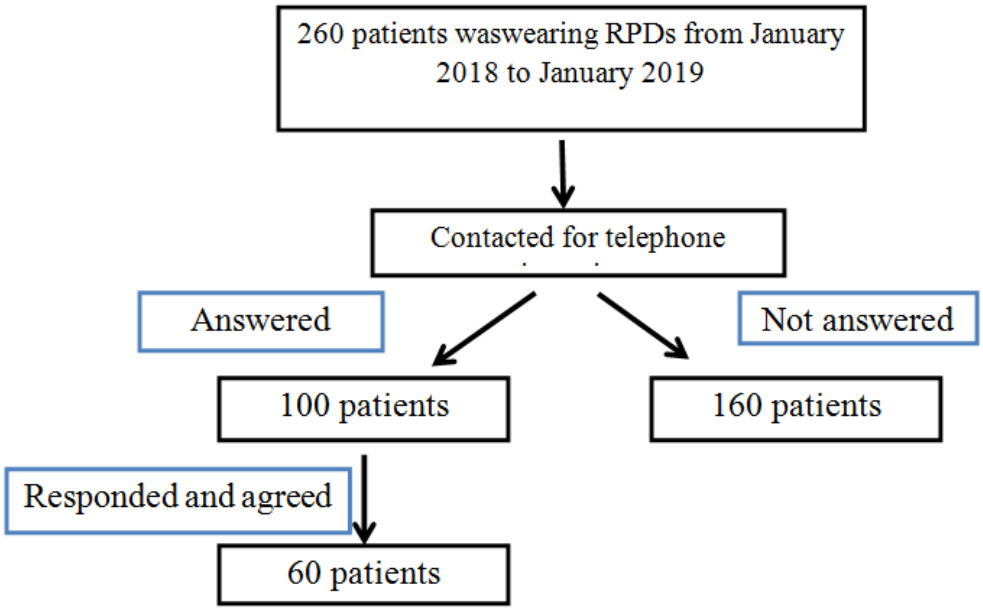

Figure (1) Patient's participation in study.

Statistical Analysis: The resulting data were entered into a statistical software program (Statistical Package for the Social Sciences, version 16.0; SPSS), which was used for all the statistical analyses. Mean ± standard deviation (SD) counts and percentages are used for recording variables. Chi-square test was applied for comparison among different variables of oral complaints related to removable prosthesis; a sample *t*-test was utilized. A *P*-value < 0.01 was the criterion for rejection of the invalid hypothesis. Data were collected from cases electronic files into a Microsoft Excel 2010.

Results

For the 260 patients who wear RPD from the three places from January 2018 to January 2019. Sixty cases (24 male and 36 female cases) participated in this survey with three types of RPDs. 34(56.66%) wore acrylic RPDs, 18 (30%) had flexible RPDs, and 8 (13.33%) wore metallic RPDs; variable information was obtained from all patients. The mean ± SD age of the cases was 49.8 ± 8.3 years for wore acrylic, 47.8 ± 8.9 years for wore flexible and 47.2 ± 7.7 years for wore metallic (range: 25–60 years) as shown in Table 1.

In table 2 Shows, the symptoms were: 23(38%) pain in eating,6(10%) esthetic problems, 16(26.66%) problems in speech, and 10(16.66%) gag reflex where 5(8.33) only had no complaint.

Table 3 shows 60 patients, 16(47.05%) were satisfied on acrylic and 14 (77.77%) were satisfied on flexible. And 6 (75%) were satisfied on metallic.

The mean level of satisfaction among the three types of RPDs was significantly different ($P < 0.01$). In cases satisfaction between flexible and acrylic RPDs was significantly different. But,between either metal or acrylic, or metal and flexible RPDs no significant differences ($P < 0.01$) were recognized.

Table 1 Patient's demographics

Type of RPD	No. of Patients	Gender		Age (Mean±SD)
		Female	Male	
Acrylic	34	19	13	49.8 ± 8.3
Flexible	18	12	8	47.8 ± 8.9
Metal	8	5	5	47.2 ± 7.7
Total	**60**	**36**	**24**	**-**

Table 2 Patient's symptoms and complaint

Type of RPD	Symptoms				
	Pain on eating	**Esthetic problems**	**Speech problems**	**Gag reflex**	**No complaint**
Acrylic	14 (41%)	3 (9%)	10 (30%)	7 (20%)	0
Flexible	8 (44%)	3 (17%)	5 (28%)	2 (11%)	0
Metal	1 (12.5%)	0	1 (12.5%)	1 (12.5%)	5 (62.5%)
Total	**23**	**6**	**16**	**10**	**5**

Table 3 Patient's satisfaction

Type of RPD	No. of patients satisfied	P values	
		Flexible	**Metal**
Acrylic	16/34	0.03	0.15
Flexible	14/18	-	0.87
Metal	6/8	-	-

*P value < 0.01.

Discussion

In this study observed the rate of complaints and satisfaction among sixty cases wearing three kinds of RPDs in Baghdad city/Iraq. According to the result of this survey indicates that the approximately half of cases were fulfilled with their RPDs. That result was in agreement with other surveys on RPDs.[26, 27] the mean age of RPD wearers in this study was 48.2 years (range: 25–60). Others studies also had the same age range.[28,18,19]

Flexible RPDs are a goodtherapy choice for partially edentulous cases due to their definitely better esthetics given by bases that copygums and teeth, also due tothem being more comfortable for cases with changing oral tissue, severe cases with microstomia, as well asdecrease of function.[22]and because of that, flexible RPDs can appropriately satisfy patients displeased with the common recovery therapy since they give an excellentfix for the cases esthetics or physical limitations.[29] It is in agreement with Sharma & Shashidhara (2014), flexible RPDs produce acceptable outcomes but short duration.[22] due to that flexible RPDs haven't been commonly used as a substitute material for denture fabrication as shown in this survey .

It is observed that patient satisfaction between different RPDs materials was varied. Acrylic resin (PMMA) RPDs were had a lowest satisfaction level, followed by metallic (chrome cobalt alloys), while the higher level of satisfaction was shown inflexible nylon-base material. These results are in agreement with those of Yoshida et al. (2011), who indicate that cases withacrylic RPDs have had a lower satisfaction levels than of those with flexible nylon-base material RPDs.[30] in spite of these results the Iraqi samples not prefer flexible RPDs because of its low duration.

Moreover, shown that a low satisfaction levels with acrylic resin base in comparison with metallic base, acrylic resin base RPDs were frequently used in this survey 34 (56.66%). These results are similartoother studies in countries in Middle East. Ismail and Hussien (2009) proposed that over 97% of Iraqi patients wore acrylic RPDs.[31] in agreement with Rahdi et al.the Kingdom of BahrainIndicates that 89% of RPDsdetermine were acrylics.[15]

Although, RPDs are commonly used for the substitute of losingteeth, The most frequent complication have been reported among different countries .[27] In this survey, pain during eating followed by speech problems are the most common complaints for RPD wearers in Iraqi cases,thatare in agreement with Akeel, in KSA, (2010).

Additionally, this survey was managed within one year of RPD utilization,that may be seen asnot enoughtime to predict the accurate levels of case

satisfaction. a sample of KSA cases, Akeel et al. (2010) indicated that 36% of RPD wearers discontinued using the RPDs one year after wearing it.[23] It was proposed that an observational study based on frequent recall time had to be developed.

Conclusion

Within the limitations of this study, approximately half of cases that tooka removable partial dentures treatment were satisfied with it, showing that the quality of RPDs(in Iraq/Baghdad city)was suitable for patients. Pain in eatingis the most common complaint that shows that dental treatments with RPDs should be provided with care when patients havepain in eating.

Ethical Clearance was obtained from Alfarahidi University, Baghdad, Iraq.

Deep Learning Classification Method to Detect and Diagnose the Cancer Regions in Oral MRI Images

M. Praveena Kirubabai[1], G. Arumugam[2]

[1]Research Scholar, [2]Head of the Department (Retd), Senior Professor, Madurai Kamaraj University, Madurai-21, Tamil Nadu, India

Abstract

The paper proposes deep learning algorithm used to classify the oral images into either normal or abnormal images. The cancer regions are segmented using morphological operations. The segmented cancer regions are further diagnosed into 'Mild' or 'Severe' using deep learning algorithm. The main advantage of the deep learning algorithm is that it requires minimum number of oral images for both classification and diagnosis stages of the proposed work. In this paper, the total number of cancers affected oral images used is about 160 and the proposed oral cancer detection system using CNN classification approach classifies 159 cancer affected oral images correctly and achieves 99.3% of detection rate.

Keywords: *Deep learning, cancer, oral images, detection system, detection rate.*

Introduction

The term cancer, means "crab" in Latin, was coined by Hippocrates in the fifth century to describe a family of diseases. The tissues grow and spread unrestrained throughout the body, eventually choking of life. Cancer, in simple terms, is the disease caused by malfunctioning of cells, lost their control on proliferation. The cluster of cells, called a tumor or a neoplasm, constantly expands in size. Occasionally, cells might spread throughout the body, forming new tumors at distant sites, and the process of dissemination is called metastasis. Cancer, a multifactorial disorder, arises due to the defect in genetic makeup and exposure to environmental insult. Oral cancer, a life-threatening cancer worldwide, arises in the oral cavity due to ill-habits such as tobacco smoking and chewing. Cancer might occur anywhere in the body and a common strategy is to name them based on the organ or the type of cell they originate; the net result is more than 100 types of cancer. Among them, oral cancer is one of the most common malignancies present in the head and neck region.

Oral cancer, a malignant neoplasm of the mouth, is the fifth most frequent cancer in occurrence and eighth most common cause of cancer related deaths worldwide. The burden of oral cancer, worldwide, is drastically increasing despite of the advanced procedures available for early diagnosis and treatment. Oral cancer rates are rising in several countries dramatically. The mortality rate due to oral cancer worldwide is 30% and 12% in male and female respectively. Tobacco smoking and chewing are considered as the major predisposing factors for the development of oral cancer. All forms of tobacco habits are significantly associated with the development of oral cancer. Smokeless Tobacco (SLT) has been accepted as one of the strongest risk factors for the development of oral carcinoma.

In this paper, deep learning algorithm such as Convolutional Neural Networks (CNN) is used to classify the oral images into either normal or abnormal images. The cancer regions are segmented using morphological operations. The segmented cancer regions are further diagnosed into 'Mild' or 'Severe' using deep learning algorithm.

Literature Survey: A hybrid method was used by combining Fuzzy C-Means and neutrosophic algorithm for segmentation of tumors in the oral panoramic image proposed by Alsmadi (2016)[4]. It used speckle reduction by 3 × 3 size median filter to reduce the speckle noise, using neutrosophy algorithm. This approach provided a significant improvement in segmenting oral lesions. The accuracy comes from the use of indeterminacy degree to cluster the region and determination of the

tumor. However, as this study was based on cluster calculation and image boundary location, shadow areas on the panoramic image will be a concern in terms of false detection. A study utilized variants of Support Vector Machine (SVM), such as Linear SVM, Quadratic SVM and Cubic SVM, were used to classify tumors on optical coherence tomography images. They compared the sensitivity, specificity and accuracy in six different classification conditions (Banerjee et al. 2016)[5]. Tanupriya Choudhury et al. (2016)[6] proposed the Intelligent Classification of Lung and Oral Cancer through diverse data mining algorithms. Logistic regression was a powerful tool modeling and also used for generalization of the linear regression. The optimal quantity of the Logic Boost iterations was performed and cross validated, taken to the selection of the attribute was automatic. Yi-Ying Wang et al. (2016)[7]presented a new color-based approach for automated segmentation and classification of tumor tissues from microscopic images. The procedure consists of a three-stage Color-Based Feature Extraction (CBFE) system. It normalized all the acquired images to the same color distribution by color transformation. Computerized selection of training samples was used for Automatic feature extraction. A similar study was made by Chang et al. (2016)[8] using hybrid feature extraction and machine learning classification algorithm with biomarkers. They proposed and tested five tumor classification method. The method, Adaptive Neuro Fuzzy Inference System (ANFIS), achieved the highest classification rate of 93.81% by combining the clinical pathologic dataset and biopsy images. This study considered patient's case as a whole. However, if the clinic pathologic dataset or images were considered as a separate sample, the result might not be achieved over 90% accuracy rate. In other words, the accuracy of the method rely on the patient's information.

An automated oral lesion detection method was studied by Galib et al. (2015)[2]. They discussed two systems to discover the two types of common lesions in the oral cavity. It achieved 92% sensitivity with 32% of false positives on average in close border lesions and 85% sensitivity with no false positives in open border lesions. Moreover, it had also discussed the possibility of improvement in open border lesion algorithm to 100% sensitivity with only 13% of false positives. Belvin Thomas et al. (2013)[3] proposed Texture Analysis Based Segmentation and Classification of Oral Cancer Lesions in Color Images using ANN. The objective was to select a reduced set of features that clearly distinguish between different groups of malignancy caused by carcinoma of different areas of oral cavity. They proposed the use of textural and run-length features of camera images. Hobdell et al. (2003)[1] investigated the relationship between socioeconomic status variables and oral health in an attempt to determine the association between social, economic and behavioral risk factors and the incidence of oral cancer among other oral health concerns. Their results described a marked gradient in oral diseases between the most highly and the least socio-economically developed countries and there was an apparent association between oral cancer and the socioeconomic status variables.

Proposed Methodology: In this paper, deep learning algorithm is used to classify the oral images into either normal or abnormal images. The cancer regions are then segmented using morphological operations. The segmented cancer regions are further diagnosed into 'Mild' or 'Severe' using deep learning algorithm. The main advantage of this deep learning algorithm is that it requires minimum number of oral images for both classification and diagnosis stages of the proposed work. Figure 1 shows the proposed oral cancer classification and diagnosis system using Convolutional Neural Network (CNN) classification approach.

Enhancement: In this paper, adaptive local histogram equalization framework is applied on the low-resolution oral MRI image for improving the intensity level of each pixel in the source image. In this section, the following steps are used to detect and remove the noisy pixels in oral MRI images.

Step 1: The source oral MRI image is divided into n*n non–overlapping sub blocks, where, n is the odd number value.

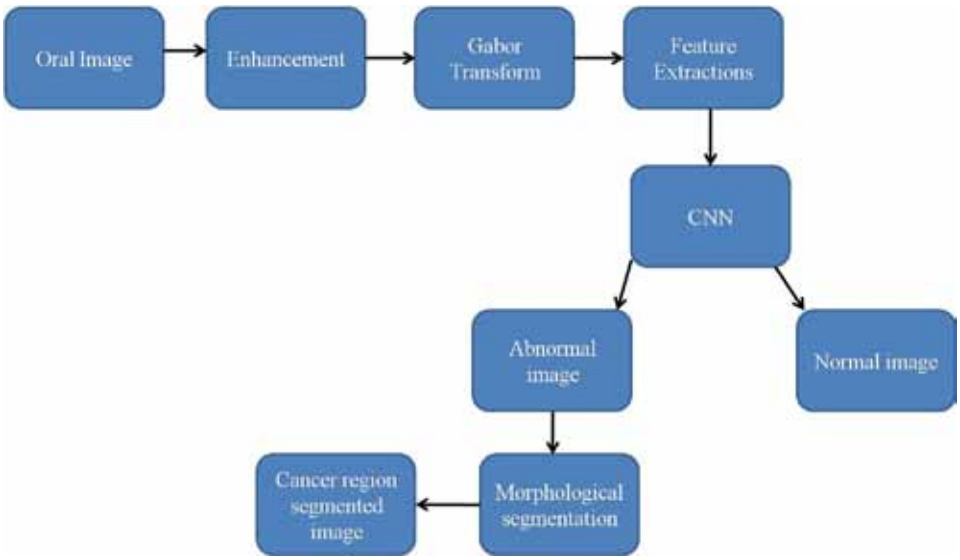
Step 2: In each n*n non–overlapping sub blocks, place the pixels in horizontal, vertical and two diagonal direction into P1, P2, P3 and P4 sets, respectively.

Step 3: Make order of pixels in P1, P2, P3 and P4 sets and eliminate the lower and higher order pixel from each set.

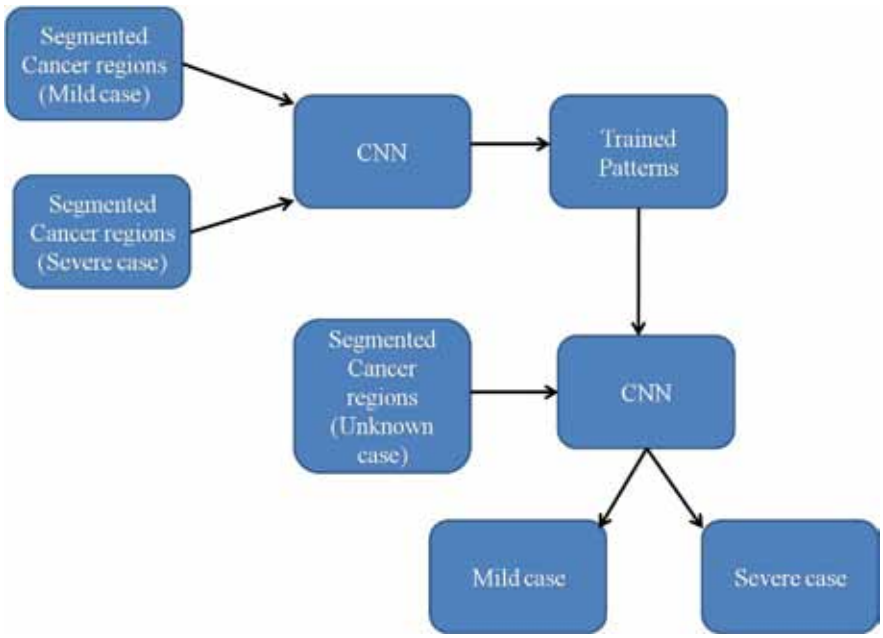
Step 4: Find standard deviation of each pixel set and find similarity index of each pixel.

Step 5: Consider the sub pixel set which has low value of standard deviation.

Step 6: Apply adaptive mean filter in the final sub pixel set in order to remove the noisy content.



(a)



(b)

Figure 1 Proposed oral cancer classification and diagnosis system using CNN classification approach (a) Classification method (b) Diagnosis method

Gabor Transform: In this paper, Gabor transform is used for spatial into multi oriented image conversion. The Gabor kernel is multiplied with enhanced oral image and the Gabor kernel is given as,

$$G(x,y) = e^{\frac{-(x^{|2}+\gamma^2 y^{|2})}{2*\sigma^2}} * Cos\,(2*\pi*f*\frac{x^{|}}{\lambda}+\varphi)$$

where,
σ: Standard deviation.
γ: Spatial aspect factor is a constant set to 1.
λ: Spatial wavelength.

$$y^{|} = -x*sin\,\theta + y*cos\,\theta$$

The frequency of the Gabor kernel is assigned by 'f' and it is shifted from 1 to 5 concerning spatial angle factor. Consequently, five quantities of Gabor kernels are created by duplicating the Gabor kernel with Oral picture concerning distinctive frequencies. These Gabor multiplied pictures comprises of real and imaginary terms. Further, Gabor magnitude image is built by choosing the maximum pixel value at each position

in the Gabor multiplied pictures (Y(x,y)) utilizing the condition.

$$Y(x,y) = I(x,y) * G(x,y)$$

where,
$I(x,y)$: Oral image;
$G(x,y)$: Gabor kernel
$Y(x,y)$: Output response of the Gabor multiplication;

$$|Y(x,y) = \sqrt{Real(Y(x,y)^2 + Imaginary\ ((Y(x,y)^2}$$

Feature Extractions: It is one type of texture features used for classifying the various regions in a Gabor transformed magnitude image. It encodes one feature value for one pixel in a Gabor magnitude oral image. The 3*3 window is placed on the Gabor transformed oral image and it computes LBP (Local Binary Pattern) for each pixel using its surrounding pixels. The size of Gabor magnitude oral image and its extracted LBP images are same.

Classification: The machine learning algorithms for cancer region detection in oral images requires number of external features. These machine learning method are not suitable for further severity diagnosis process. In order to overcome such drawbacks the conventional machine learning method called deep learning method - Convolutional Neural Networks (CNN) is used in this work to detect and diagnose the cancer regions in oral images. As in machine learning algorithm, CNN also have both training and testing phases. During the training phase of the CNN classifier, the normal oral images and abnormal oral images are trained by the CNN producing the trained patterns. During the testing phase of the CNN classifier, the source oral image is tested with respect to the trained patterns. The response from this CNN classifier is either normal or abnormal. The CNN architecture used in this research work is depicted in Figure 5.

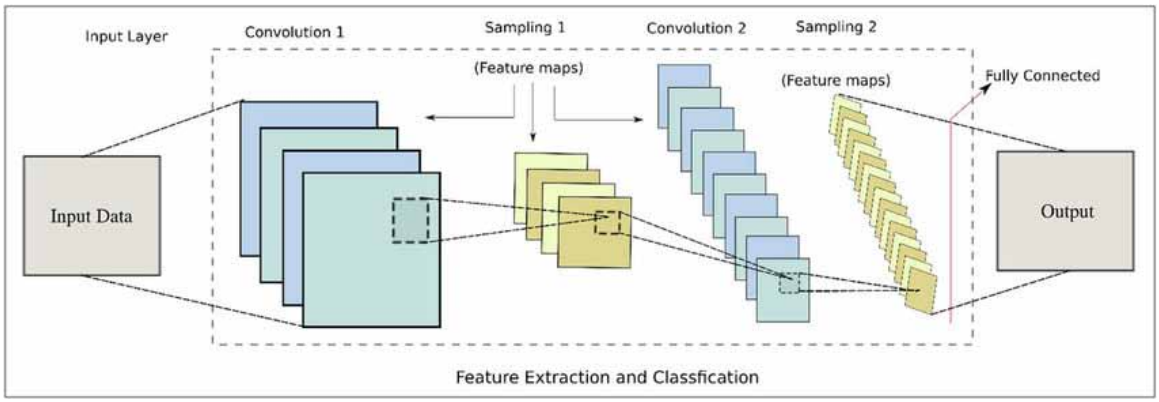


Figure 5 CNN architecture

The CNN architecture includes Convolutional layers, pooling layers, and fully connected layers. The Convolutional layer consists of a number of convolution kernels, which is a two-dimensional matrix of weights W. The convolution kernel convolves an input image (also a two-dimensional matrix) in the form of a sliding window with a matrix called feature map is obtained. Each Convolutional layer has Convolutional kernel itself and it is convolved with the oral image. The pooling layer is also called the sampling layer, uses the sliding window to convolve the input or the feature map so that it might reduce the feature dimension and the amount of calculation. Polling layer has two different types as "Average" and "maximum" pooling. Different from the Convolutional layer, the pooled layer (maximum pooling is adopted in this paper) does not depend on weights and parameters. In general, each feature map of the input is pooled in the same way and the number of features of the original input remains unchanged. Then, the fully connected layer is used to map the feature representations from the Convolutional layer to the sample space in order for classification, composed of a group of neurons and connections with weighted values. Since the number of the parameters of the fully connected layers is very large, some networks use the Convolutional neural networks to take place in the fully connected layers. The proposed CNN method for oral cancer image detection and classification is depicted in the following algorithm.

Input: Oral image;

Output: Classification response;

Start;

Step 1: The input oral image is convolved with kernel of first Convolutional layer and the response is produced.

Step 2: The size of the convolved sequences are reduced by passing these values through the pooling layer 1.

Step 3: The size reduced sequences are now passed through the Convolutional layer 2.

Step 4: The response from the second Convolutional layer is passed through the second pooling layer.

Step 5: The output response from the second Convolutional layer is feed into neural network architecture to produce the classification pattern.

End;

Further, mathematical morphological operations are used to segment the cancer regions in classified oral images. The morphological parameters such as area, width and height are computed for its diagnostic process. The segmented oral cancer regions are analyzed for the mild and severity of the cancerous regions using CNN classification.

Results and Discussions

The proposed fully automated oral cancer detection and diagnosis system is divided into two different sections as cancer region detection or segmentation and cancer region diagnosis. This automated cancer region detection and segmentation approach on oral images is applied on the oral images obtained from the open access dataset. The performance of the proposed oral cancer region segmentation on oral images using classification method is evaluated in terms of sensitivity, specificity and accuracy. These performance evaluation metrics are given in the following equations.

$$Sensitivity = \frac{TP}{TP + FN}$$

$$Specificity = \frac{TN}{TN + FP}$$

$$Accuracy\ (Acc) = \frac{TP + TN}{TP + TN + FP + FN}$$

The number of correctly detected cancer pixels in the classified abnormal oral image is noted by True Positive (TP), the number of correctly detected non-cancer pixels in the classified abnormal oral image are noted by True Negative (TN). The number of incorrectly detected cancer pixels in the classified abnormal oral image is noted by False Positive (FP), the number of incorrectly detected non- cancer pixels in the classified abnormal oral image are noted by False Negative (FN).

Table 1 shows the performance evaluation of oral cancer detection and segmentation using CNN classification method and it achieves 98.6% of sensitivity, 99.1% of specificity and 99.7% of oral cancer segmentation accuracy.

Table 1 Performance evaluation of oral cancer segmentation using CNN classification methodology

Parameters	Simulation results (%)
Sensitivity	98.6
Specificity	99.1
Accuracy	99.7

Table 2 shows the analysis of data augmentation method in CNN architecture on proposed oral cancer detection and segmentation.

Table 2 Analysis of data augmentation method in CNN architecture on proposed oral cancer detection and segmentation

Performance parameters	With Data Augmentation	Without Data Augmentation

Conclusions

This paper develops a methodology using deep learning algorithm to classify the oral images into either normal or abnormal images. The cancer regions are segmented using morphological operations. The segmented cancer regions are further diagnosed into 'Mild' or 'Severe' using deep learning algorithm. The main advantage of this deep learning algorithm is that it requires minimum number of oral images for both classification and diagnosis stages of the proposed work. In this paper, the total number of cancers affected oral images used is about 160 and the proposed oral cancer detection system using CNN classification approach correctly classifies 159 cancer affected oral images correctly and achieves 99.6% of detection rate.

Abstract

Introduction: The emerging technologies made by day changing the techniques of teaching medical education. The teaching technique has changed since the last decade from the old traditional technique of chalk and talk (CNT) to a newer technique of Power-point presentation (PPT) to the video classrooms converting the whole traditional environment of the classrooms. This paper aims to access the perception of the medical students about these two instructional method.

Materials and Method: In this study cross-sectional descriptive survey was used. Medical students were selected through non-probability convenient sampling. The data were collected using a questionnaire-based survey about their views and perception of two method of lecture delivery, viz., PPT presentation, and using a chalkboard. For each of the two method, the students were asked to rank twelve comments on a four-point scale: strongly agree, agree, disagree, or strongly disagree. The data was analyzed using SPSS version 16 and the results expressed as proportions.

Results: In our study where more than 97% of our study respondents emphasized the value of chalk and talk and declared it as the more effective and useful teaching tool in their learning experience compared to PowerPoint (86%) and recommended it for teaching.

Conclusion: Both CNT, as well as PPT, are the effective method for medical education and both can be used in combination for the effective delivery of classroom sessions.

Keywords: *Teaching method; medical education; classroom techniques.*

Introduction

Lectures have been the most common form of teaching and learning since ancient times.[1] Although discussion method in small groups appear to be a superior method of attaining higher-level intellectual learning.[2]

During the past few decades, the presentation method in the classrooms have changed from the traditional CNT to the modern technique of PPT. The most accepted criterion for measuring good teaching technique, however, is the amount of student learning.

Students often have little expertise in knowing if the technique selected by an individual instructor was the best teaching technique or just 'a technique' or simply the technique with which the teacher was most comfortable.[3]

During a lecture, both the visual and auditory senses are used to absorb information and here assistance in the form of the visual aid is useful.[4] A chalkboard is

uniquely effective as a medium of classroom instruction and has been used commonly in lectures, while the use of transparencies with an overhead projector (TOHP) is also popular.[5]

In traditional classrooms, a teacher's basic instructional tools for displaying information are chalkboards, multipurpose boards, pegboards, bulletin boards, and flip charts.[6] To project instructional materials, overhead transparencies displayed via an overhead projector are still a commonly used classroom presentation method.[3] Recently the use of electronic presentations has become common and PPT is now the most popular instructional aid.[7]

The impact of technology has led to the increased use of computers for presenting information in many of today's classrooms. PPT hailed as an easy-to-use means of creating professional presentations teachers for creating classroom presentations.[8] A study found PPT to be one of the most widely used software programs in both an area educator preparation program and local public schools.[9] It is seen that "more than 400 million copies of the program are currently in circulation, and somewhere between 20 and 30 million PPT-based presentations are given around the globe each day".[10]

Various studies have been conducted to assess the effectiveness of lectures using PPT or other such media in comparison to lectures using the chalkboard, or the use of TOHP. According to one study, traditional classes with blackboard presentation were the most favoured by students from biomedicine and medicine courses.[11]

Recently the use of electronic presentations has become common and PPT is now the most popular package used out of all electronic presentations.[12]

Therefore, the present study was aimed, to assess the student's perceptions of the impact of PPT presentations in lectures compared with the traditional CNT.

Materials and Method

This is a cross-sectional descriptive study. Medical students were selected through non-probability convenient sampling. The data were collected during 2017 from the undergraduate medical students at Gauhati Medical College and hospital using a questionnaire-based survey about their views and perception of two method of lecture delivery, viz., PPT presentation, and using a chalkboard. For each of the two method, the students were asked to rank twelve comments on a four-point scale: strongly agree, agree, disagree, or strongly disagree. The data was analyzed using SPSS version 16 and the results expressed as proportions. As this study is on classroom technique and has not revealed the identity of any of the participants, so ethical clearance from the ethics committee is not required. However, informed consent was taken before the collection of the data.

Results

Distribution of perception of undergraduate medical students regarding the method of the CNT is narrated in **Table 1**.

Table 1 Distribution of perception of UG medical students regarding the method of chalk and talk

Sl.No.	Statements regarding perception	Strongly Agree	Agree	Disagree	Strongly disagree
		%	%	%	%
1.	I understand the lecture better when the teacher uses this technique	26	71	2	1
2.	I feel the student interaction is better with the teacher	33	53	12	2
3.	Eye contact between teacher and student is less	14	41	36	9
4.	The lecture advances the understanding	20	67	12	1
5.	This technique helps me to concentrate and remember better	38	50	10	2
6.	The quality and quantity of my lecture notes can't be maintained	12	48	30	10
7.	The delivery of lecture is interesting	26	51	20	3
8.	The content of the lecture informative	19	68	11	2
9.	The lecture is audible	28	65	7	0

Sl.No.	Statements regarding perception	Strongly Agree	Agree	Disagree	Strongly disagree
		%	%	%	%
10.	The lecture content was well organized	30	47	20	3
11.	The teacher remains more professional	25	59	15	1
12.	The teacher needs more preparation for the class	30	50	18	2

The distribution of perception among the undergraduate medical student regarding PPT as a method of teaching is narrated in **Table 2**.

Table 2 Perception of undergraduate medical students regarding PPT

Sl.No.	Statements regarding perception	Strongly Agree	Agree	Disagree	Strongly disagree
		%	%	%	%
1.	I understand the lecture better when the teacher uses this technique	30	56	12	2
2.	I feel the student interaction is better with the teacher	29	45	24	2
3.	Eye contact between teacher and student is less	14	47	34	5
4.	The lecture advances the understanding	19	65	16	0
5.	This technique helps me to concentrate and remember better	30	46	21	3
6.	The quality and quantity of my lecture notes can't be maintained	12	48	37	3
7.	The delivery of lecture is interesting	20	58	22	0
8.	The content of the lecture informative	20	71	7	2
9.	The lecture is audible	24	64	12	0
10.	The lecture content was well organized	35	50	10	5
11.	The teacher remains more professional	27	52	20	1
12.	The teacher needs more preparation for the class	31	42	23	4

In the present study, 97% of the participants emphasized the value of chalk and talk and declared it as the more effective and useful teaching tool in their learning experience as compared to PowerPoint (86%) and recommended it for teaching.

Discussion

Teaching is an art. This study highlights the fact that the favourite stechnique of lecture delivery for students by different faculties in the classroom can vary so much within the same college.

Different technologies are available in classrooms for teaching in the present day scenario. The use of better teaching technique aid allows students to understand better. This also allows more time for interaction and further understanding. Use of technology can be a very beneficial and time-saving tool for all teachers.

An evaluation by the students can provide the teacher with the best user feedback regarding the best teaching method.

In the present study, medical students favoured a combination of teaching aids rather than single teaching support. Regarding the preference of medical students, the order of priority of combined teaching aids they have opted was PPT+CNT using blackboard.

This preference may probably be because the inherent deficiency of each method is compensated by the other. While CNT using blackboard teaching is deficient in showing the three dimensional (3-D) diagrams, animated videos and real-time sounds. However, the same can be demonstrated using a PPT. Furthermore, PPTs take less time to present the same information as compared to CNT using blackboard teaching. CNT teaching allows the students to take down the notes and diagrams which

is difficult with PPTs as there is a tendency to deliver the lecture fast.[13]

The current results agree with Chaudhary R et al.[14] Here the author revealed that the majority of the students (67.1%) favoured the combined teaching aids. With the CNT using blackboard, the student pointed the drawback, is that it takes time to draw a labelled diagram on the board and during that time teacher's eye contact with the students get interrupted.

SN Baxi et al.,[15]in their study, revealed that an equal number of students preferred CNT and multimedia-based lectures. Seth et al.,[16] also compared the preference for teaching aid between medical students versus dental students. The medical students have preferred PPT whereas the dental students preferred the Chalkboard in their study.

Some participating students opined that the effectiveness of the teaching lecture depends upon the teacher, regardless of the teaching aid used. What is fundamentally important in university teaching is not the quality of the technology but the quality of the teacher as revealed in a stduy[17] agree the current results. Besides, a good teacher knows to start at a basic point of the course, which students can understand and then lead them gradually through the new and more difficult points.[18]

Conclusion

In conclusion, combined teaching support is considered as most satisfying teaching support because the inherent deficiency of one aid is compensated by the other. If single teaching assistancesis to consider then the blackboard teaching aid is the most pleased by the undergraduate medical students as they can follow the teacher well with a deep understanding of the concept effectively.

The present study, as well as the previous studies, does not bring out the superiority of any single support system of the teaching method. It seems that with the hands of a trained teacher any teaching technique would be suitable and effective. This highlights the need for formal training of the teachers in teaching in the classroom to develop a perfect skill to motivate students.

In-vitro Cytotoxic Activity of E. *coli* Outer Membrane Vesicles (OMVs) Against Breast Cancer (MCF-7) Cell Line

Mahmood Abed Hamzah[1], Ali Husain Alwan[2], Suzan Saadi Hussain[2]

[1]PhD Student, [2]Prof., Department of Biology, College of Science, Al-Mustansiriyah University, Iraq

Abstract

Twenty-five samples of urine were collected from patients suffering Urinary Tract Infection (UTI) from hospital in Baghdad,twenty-two bacterial isolated (88%) were identified. From our result showed the *E. coli* number 5 is the best bacterial virulence factor for producing OMV, Tumor cells ($1x10^4$ – $1x10^6$ cells/ml) have been grown in 96 flat well micro-title plates, with a final volume of 200 cells per well. The microplate was gently shackled and covered by sterilized parafilm then incubation of the plates at 37C°, 5 % CO_2 for 24hrs. Two folded serial dilutions of the desired compound (12.5, 25, 50, 100, 200, 400µ g/mL) were added to the wells after incubation. Triplicates were used per each concentration as well as controls (serum-free medium treated cells). Plates were incubated for specified exposure time (24 hours) at 37C°, 5 percent CO2. Applied 10µ liters of MTT solution to each well after exposure. The absorbance was determined by a wavelength of 575 nm using an ELISA reader. Statistical analysis was performed on the optical density data to calculate the compound concentration required to cause a 50 percent reduction in cell viability for each cell line. The rate of cell growth inhibition (the cytotoxicity percentage) was calculated and plot of % cytotoxicity against sample concentrations assisted to calculate the concentration which exhibited 50% cytotoxicity (IC_{50}). Calculate: cell number: determine cells per milliliter.

Keywords: *Cytotoxic Activity; E. coli; outer Membrane Vesicles (OMVs); breast cancer (MCF-7).*

Introduction

Outer membranes vesicles (OMVs) can to transfer biological molecules to host cells and their development among gram-negative bacteria is intended. Apart from their role in the communication of bacteria, virulence factors are transferred to the host for cargoes to OMVs to boost bacterial survival[(1).]

Outer membranes vesicles have properties which permit the transmission of DNA fragments, autolysins, cytotoxins, virulence factors, and various other biomolecules to be mediated by them and their secretion allows bacteria to interact with and within the species and also strengthens their contact with the host. OMVs were recognized for their role in nutrient procurement, stress reactions and toxin transmission, adherence to and virulence factors in avoiding host defense systems among the prominent roles in various pathological and physiological [(2,3).]

Cancer is an uncontrolled cellular development and spreading disease, where cells do not respond to the normal controls and cause the tumor to grow and to metastasize[(4).] However, chemotherapy does not target drugs directly in cancer sites, which ensures that healthy cells are susceptible to adverse reactions. Also because of its fast removal and nonspecific distribution, a large dose is needed[(5).] The goal of nanomedicine is to identify cost-effective molecules with high cell specificities and susceptibility[(6).]

Cancers' immunotherapy may be categorized as immunothérapic therapies with the goal of utilizing innate or adaptive immunity in oncology[(7)].

Nevertheless, the successful treatment and eradication of cancer tumors have been avoidable due to inadequate induction of immune responses using conventional vaccination approaches, despite the tremendous potential of cancer vaccines[8]. It highlights the need for new vaccine approaches, in which tumor antigens and APC adjuvants are administered effectively and with a good enough immune response to kill tumor cells. Over the past three decades, nanoparticles have been intensively studied as a delivery method of modern chemotherapy over firm tumors [9,10].

Material and Method

Method for preparation of outer membrane vesicles (OMV): Overnight on lysogeny broth, bacterial cells were cultivated with shaking at 37 °C (150rp.m.) until the OD600 reached 1.5 (1 percent tryptone, 0 percent yeast extract, 1 percent NaCl, 7.0 pH). At 5000rpm twice for 20min, at 4°C, the cultivated cells were pelleted. The supernatant was filtered with a 0.4 5 µm pore filter and then applied supernatant to cold absolute ethanol at 4ºC (twice the volume of supernatant), which lasted 24 hours. This resulted in rough precipitation isolation. The precipitation was dissolved in deionized water and dialysed using a 14000D tubular dialyzis membrane for 24-48 hours with Spectra/Por molecular pore.At 15000rpm twice for 20min, at 4°C, the precept cells were pelleted by using high speed centrifuge. A filter with a pore size of 0,22µm and the OMV pellet were filtered again into water and held at −80 °C for further experiments.

Gel chromatography purification: The Pharmacia Fine Chemicals Company has prepared Sephadex G-200 as recommended. A quantity of Sephadex G-200 has been suspended, degassed, and wrapped in 0.1 M Tris-HCl buffer pH8 (1.5x80 cm), the gel has been preserved for 72 hours. Then balanced with the same buffer at room temperatures for swelling. Elution was done at a flow rate of 30 ml/hr and the same control buffer was used. At 280 nm, absorbance was measured for each fraction.

In-vitro cell line design: From the National Center for Cell Sciences (NCCS) Pune, breast cancer MCF-7 cell lines were obtained. The cells were maintained in a humidified atmosphere of 50 lg/ml CO2 at 37 LC in Limited Essential Media supplemented with 10 percent FBS, penicillin (100 U/ml), and streptomycin (100 lg/ml).

Cell Preparation:

1. The medium EMEM containing: 10% bovine serum fetal, 1mM pyruvate, 100 units of penicillin, and 100µg/ml streptomycin (EPEM full solution), 1X non-essential amino acids. It was used to treat the following compounds.
2. When 90% confluence was reached at a dilution of 1:4, MCF7 cells were divided. Using several of cells at passage = 10.
3. Tripsinisation of MCF7 cells, diluting to EMEM, was conducted on a complete medium and cell density. In complete EMEM, cells have been diluted into 7.5 to 104 cells/ml.
4. In each 96-well-microplate well the cell suspension (100 µl) has been added to achieve 7.500cells/well (7.500cells/well- recommended planting density).
5. Overnight the cells have been incubated at 37 °C with 5 % CO2.

Cell Line Maintenance[11].

The following protocol was performed when the cells in the vessel formed confluent monolayer:

The cell sheet was washed with PBS.

A. The growth medium was drained.

B. The cell has been given two to three ml of tetraacetic ethylene diamine (EDTA) solution. The ship was transformed into a soft rocking cover for the monolayer. The vessel allowed incubation of the cells at 37 °C for between 1 to 2 minutes.

C. The cells were dispersed from the wedding surface into the pipetting medium for production. This medium was applied to the Fresh RPMI medium (15-20 mL).

Incubated at 37 °C and distributed in 5% of the CO2 incubator D- cells were redistributed in cultivated vessels, flasks or plates whatever is required.

By using the hemocytometer and using the formula, cell concentration was determined by counting the cells:

Total Cell Count/ml: Cell count x dilution factor (sample volume) x 10^4

MTT Protocol: The cytotoxic effect of different compounds isolated from Ag Nanoparticles, OMVs, and combination of OMVs and Ag Nanoparticles was performed using MTT ready to use the kit.Tumor cells ($1x10^4$ – $1x10^6$ cells/ml) have been grown in 96 flat well

micro-title plates, with a final volume of 200 cells per well. The microplate was gently shackled and covered by sterilized parafilm. Incubation of the plates at 37C°, 5 % CO_2 for 24hrs. then two folded serial dilutions of the desired compound (12.5, 25, 50, 100, 200, 400µ g/mL) were added to the wells after incubation. Triplicates were used per each concentration as well as controls (serum-free medium treated cells). Plates were incubated for specified exposure time (24 hours) at 37C°, 5 percent CO2.10µ liters of MTT solution was applied to each well after exposure. Plates were further incubated for 4 hours at 37 °C, 5 % CO2. Carefully removed media and added 100µl of solubilization solution per well for 5 minutes. The absorbance was determined by a wavelength of 575 nm using an ELISA reader. Statistical analysis was performed on the optical density data to calculate the compound concentration required to cause a 50 percent reduction in cell viability for each cell line. The rate of cell growth inhibition (the cytotoxicity percentage) was calculated as the following equation:-

% Cell viability = (Absorbance of treated cell/ Absorbance of the non-treated cell) x 100.

% Cytotoxicity = 100 – cell viability.

IC50 (Dose concentration that inhibited cell growth by 50%)values were calculated by the linear and logarithmic correlation equation.

A plot of % cytotoxicity against sample concentrations assisted to calculate the concentration which exhibited 50% cytotoxicity (IC_{50}).

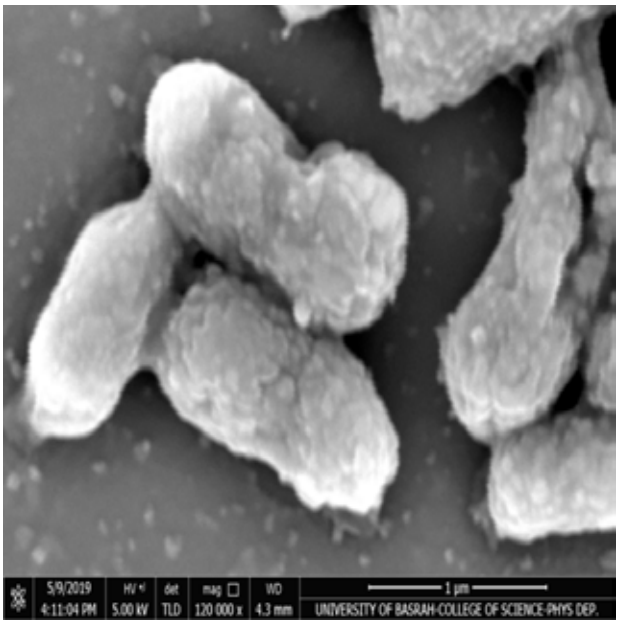
Calculate cell number: determine cells per milliliter by the following calculation:

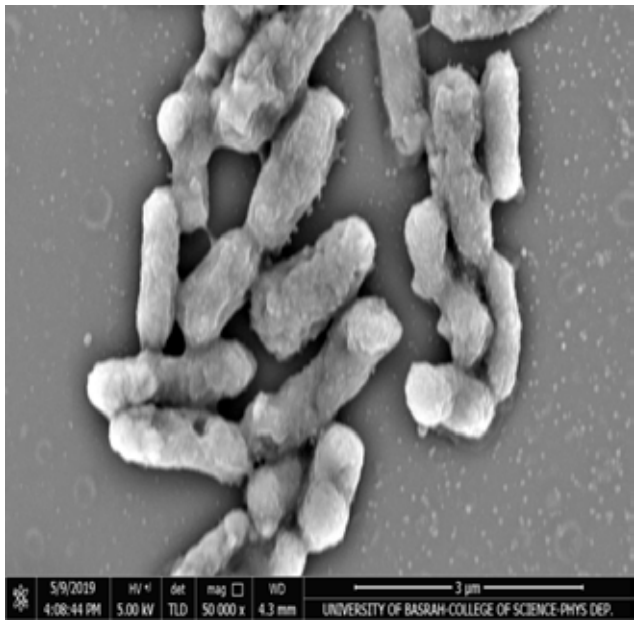
Cells/mL = average count each square × dilution factor × 10^4 total cells=Cells/mL × total unique volume of cell suspension from which sample was occupied. The number 10^4 is the volume correction factor for the hemocytometer: each square is 1× 1 mm also the depth is 0.1 mm.

Results and Discussion

The results of screening the highest and best bacterial virulence factors isolates for producing OMV showed that isolate number five 5 is the best for the ability to produce OMV Figure (3-6) and (3-7) with an average diameter of 61.08 – 103.2 nm.

Isolation OMV: The results of screening the highest and best bacterial virulence factors isolates for producing OMV showed that isolate number five 5 is the best for the ability to produce OMV Figure (1 & 2) with an average diameter of 61.08 – 103.2 nm.





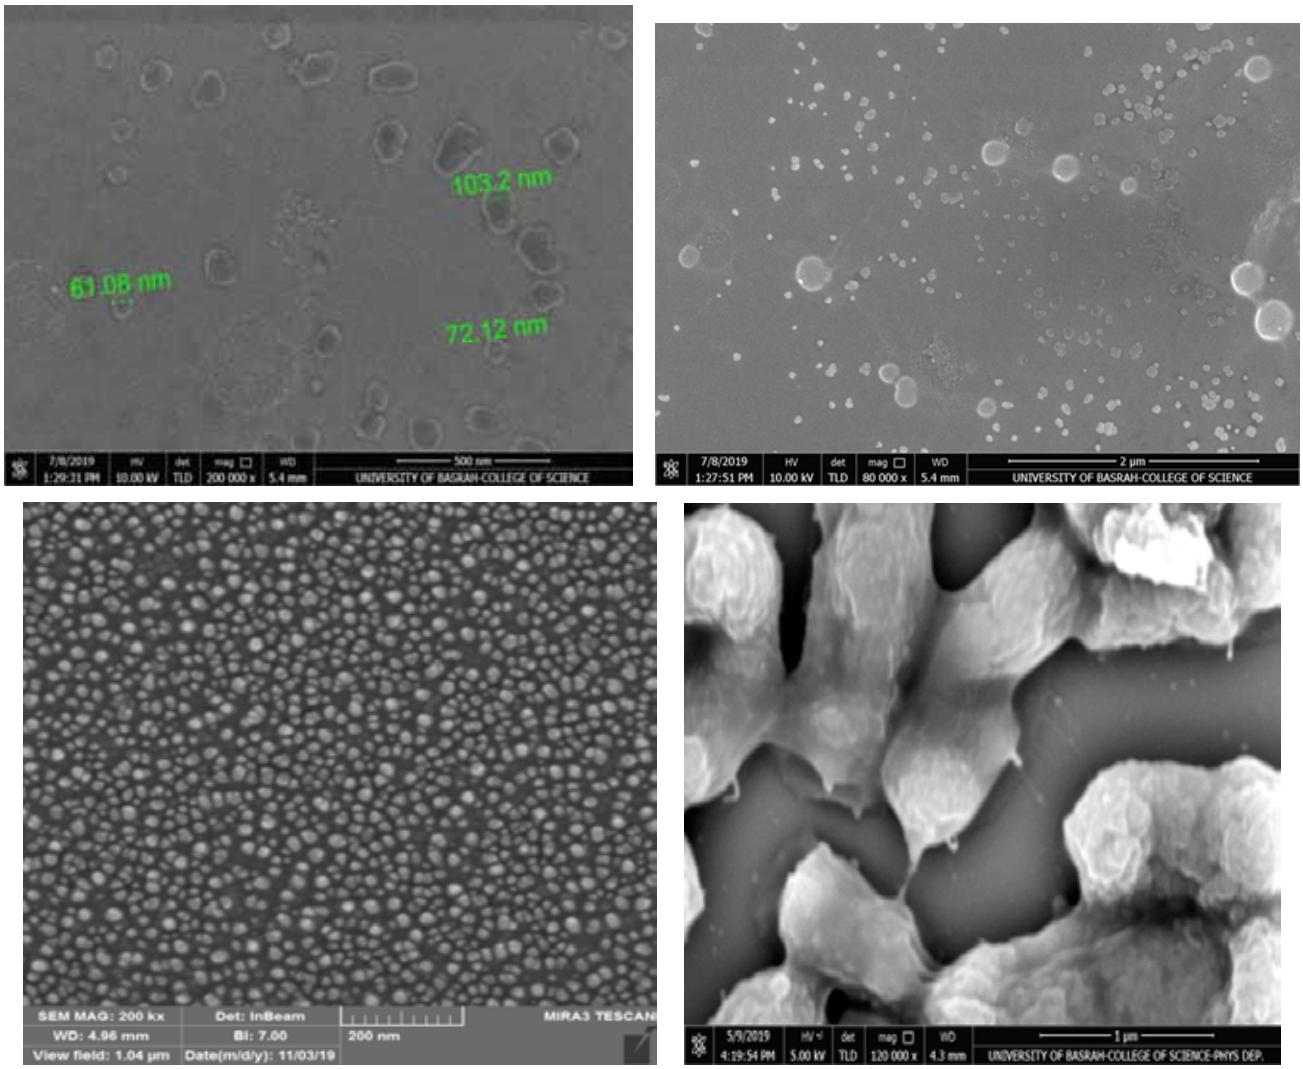


Figure (1): SEM shows the ability of isolate no. 5 to produce outer membrane vesicles (OMV)

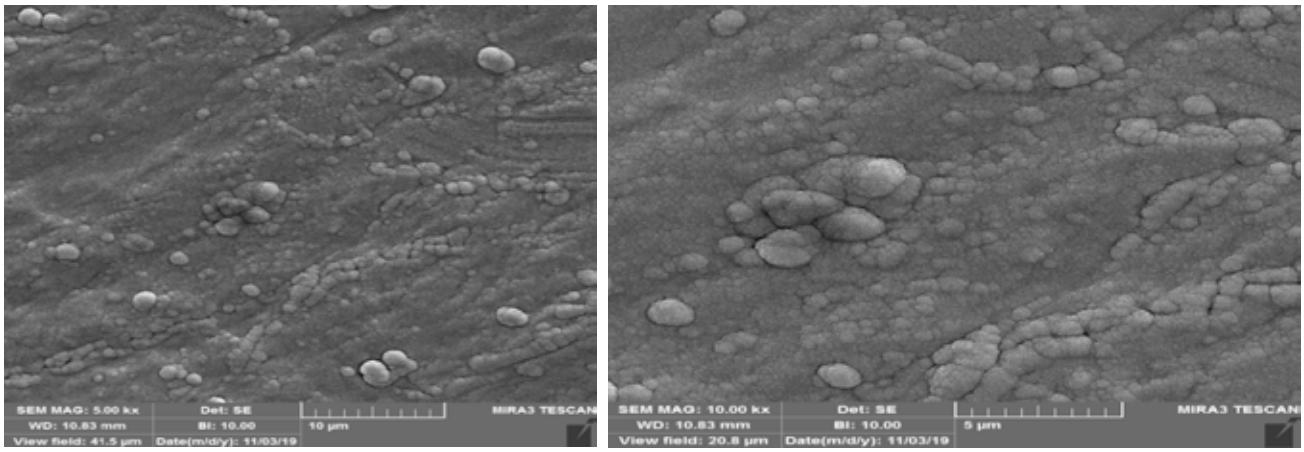

Figure (2): SEM shows the ability of isolate no. 5 to produce outer membrane vesicles(OMVs) by gel filtration chromatography method

Kim *et al* . (2017) have shown both *E. coli* wild type and mutant bacteria-derived OMVs have nano-dimensional lipid-bilayer vesicular structures, both *E.coli* of which showed with an average diameter of 38.6±3.6 and 38.7±4.2 nm along with the wild-type *E. coli*, OMVs had a higher range of production. OMV *E.coli*, giving an extra advantage of OMVs, as naturally generated OMVs have low productivity issues[12].

Behrouzi *et al.,* (2018) showed that the extracted OMV was 20–75 nm from the disease strain, whereas the OMV was 45–270 nm from the non-pathogenic strain[13]. Rolhion *et al*., (2005) showed that the pathogenic strain may produce significantly smaller vesicles than the non-pathogenic strain[14], they demonstrated that adequate-invasivity *Escherichia coli* strain LF82 can invade the cultivated intestinal epithelial cells recovered from chronic injury of a patient with Crohn9s disease. Anand and Chaudhuri., (2016) have shown that both pathogenic and nonpathogenic bacteria are made of outer membrane vesicles (OMVs) (50-250 nm in diameter) as the canonical result of secretion[15].

Table (1): Percentage of cell viability MCF-7cancer cell line to E.coli Outer Membrane Vesicles (OMV) at different concentrations

Row Stats	X Title	A		B	
		MCF-7		WRL68	
	X	Mean ±SD	N	Mean ±SD	N
1	400.000	44.414±5.048	3	76.196±3.855	3
2	200.000	44.421±9.090	3	85.957±2.609	3
3	100.000	54.553±1.860	3	93.596±2.100	3
4	50.000	59.568±0.821	3	95.332±1.183	3
5	25.000	72.801±0.904	3	95.216±0.821	3
6	12.500	85.687±4.186	3	95.949±1.028	3

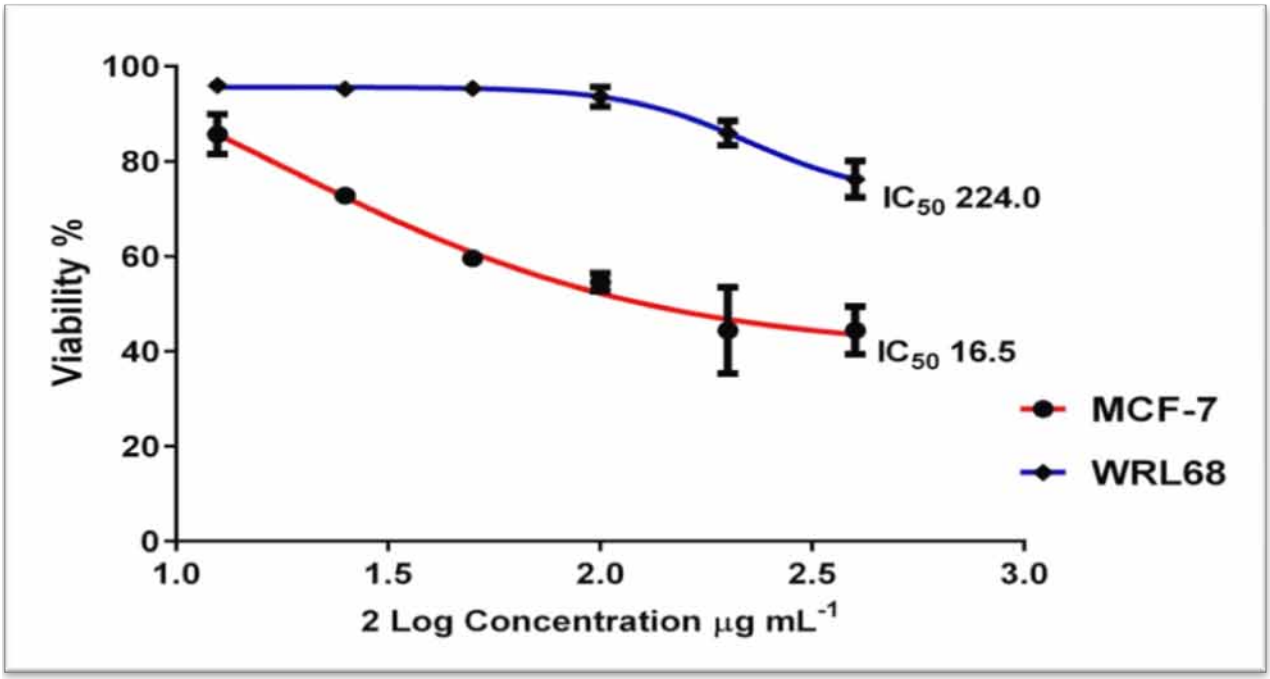

Figure (3): Shows Cytotoxic activity of isolate no.5 outer membrane vesicles against Breast cancer (MCF-7) using MTT test after 24 h. and 37o C.

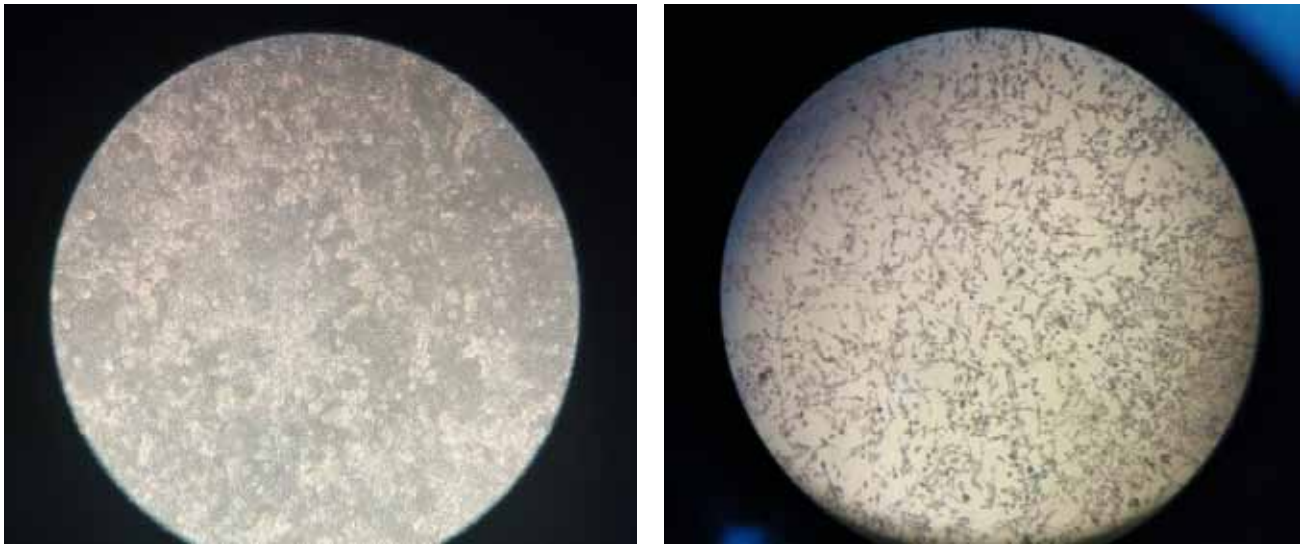
The IC50 which is the half- maximal inhibitory concentration for cell growth constructing adose response curve was measured. outer membrane vesicles showed IC50 16.5 µg/ml compared with WRL68 showed IC50 224µg/ml.

At a concentration of 12.5 µg/ml, 85.687% cell viability was observed after treatment with OMVs. However, cell viability reached to 44.414% using 400Mg/ml concentration with OMVs.

Zhang *et al*.,2019 demonstrated in many studies the propensity for immunization with OMV components can be caused by OMV **(16).** Toxins can act as adhesives for OMVs and thus enable vesicles to enter cells via the endocytic pathway through a receptor. The host cell input could also be supplemented by common components of vesicles, such as outer membrane protein A (OmpA), this adhesive is fully activated in the OMV membrane rather than as a mixture of purified vesicle components, when it is presented. OMVs are sized (20-200 nm) and can present a variety of surface antigens in a native conformed that enables them to be introduced to lymph vessels and taken up by APCs. The natural features of OMVs like immunogenicity, the ability to act as self-adjuvants, and the ability of immune cells also make them appealing for use as pathogenic bacterial vaccinations.



(a) **(b)**

Figure (4): Showed the (a) untreated MCF-7 tumors cell mass showing the proliferating tumor cell (b) treated MCF-7 tumors cell showing massive area of MCF-7

Bélteky *et al.,* (2019) showed thatcell viability assays on human A549 adenocarcinoma as well as on non-cancerous MRC-5 fibroblast cells**(17).** The aggregation dependent toxicity of both AgNP samples was investigated at nanoparticle concentrations corresponding to the respective cell line-specific IC50 (A549: IC50AgNPC =72.2±4.1 ppm; IC50AgNPGT =63.1±3.8 ppm; MRC-5: IC50AgNPC =17.6±3.0 ppm; IC50AgNPGT =1.3±0.2 ppm).

Nazir *et al.,* (2011) reported that for both cell lines Human cancer cell lines HT144 (malignant melanoma of skin) and H157 (squamous cell lung carcinoma) against silver nanoparticles, cytotoxic activity was observed**(18).** The 50% inhibition dose of growth (ID50) at 3.6 µM was observed. It was further observed that the nanoparticles had an immediate effect as observed under the Inverted Light Microscope following treatment with silver nanoparticles. There was a clear morphological change in cells under the microscope when they lost their attached nature and got rounded.

Conclusion

In *vitro* experiment showed the OMV optimum cytotoxic activity against breast cancer(MCF- 7) cell line by MTT method, the result showed 44.414% cell viability.

The Predictive Value of Serum Progesterone and Estrogen Recepters as Diagnostic Tool for Premature Ovarian Failure

Mahmood Khalil Ibraheem[1], Mutazsabahahmied[2], Firas Shawqi Algburi[3], Amina Hamed Alobaidi[4]

[1]Clinical Biochemistry Specialist, Tikrit University College of Medicine, Tikrit Iraq, [2]Assistant Professor, Tikrit University College of Medicine, Tikrit Iraq, [3]Assistant Professor, Tikrit University College of Science, Tikrit Iraq, [4]Assistant Professor, Kirkuk University College of Veterinary Medicine, Kirkuk

Abstract

Background: Premature ovarian insufficiency (POI) is a delicate medical problem in young women. This condition is not unchangeable and permanent but is associated with intermittent and unpredictable ovarian activity, resulting in low conception rate. Over the period of 8 years, the evaluation of secondary amenorrhea was conducted in 90 patients below the age of 40 who wished to restore fertility and is characterized by irregular or absent periods and reduced fertility. Symptoms include those associated with the natural menopause (night sweats and vaginal dryness), and with the long-term adverse effects of estrogen deficiency (osteoporosis and cardiovascular disease): The latter is believed to explain the shorter life expectancy associated with POI.

Aim: To illustrate the predictive value of progesterone receptors (PRs), estrogen receptors (ERs), progesterone (PRG), estradiol (E2), Lulilizing hormones (LH), Follicle stimulating hormones (FSH) and Anti mullerian hormones (AMH) serum levels as diagnostic approach for POI.

Method: Sixty (60) women with idiopathic POF with thirty (30) women as control groups were included in the study. Baseline investigation in all subjects included serum progesterone receptors(PRs), estrogen receptors(ERs), progesterone (PRG), estradiol (E2), Lulilizing hormones (LH), Follicle stimulating hormones (FSH) and Anti mullerian hormones (AMH) levels were estimated using appropriate assays in biochemistry laboratory.

Results: There was statistically significant differences in the serum progesterone receptors, estrogen receptors, progesterone, estradiol, LH, FSH and AMH in POI cases when compared with healthy control (P=<0.05).

Conclusion: These results indicate that serum progesterone and estrogen receptors levels, is high in POI cases as a result of lack progesterone and estradiol hormones as a result of loss negative feedback inhibition,this result may be used to primary diagnosis of premature ovarian failure.

Keywords: *Premature ovarian failure (POF), Anti mullarian hormones(AMH), progesterone receptors (PRs), Estrogen receptors (ERs).*

Introduction

Premature ovarian insufficiency (POI) is an early event in the reproductive life span with a significant impact on several dimensions of women's well-being and general health[(1)]. It affects 1% of women under age 40 years, 0.1% of women under age 30 years, and 0.01% of women under 20 years of age[(2)]. POI prevalence appears to vary by ethnicity, being higher in women from African and Latin American countries[(3)]. Such terminology describes the spectrum of conditions associated with the loss of ovarian function prior to the natural age of menopause. It includes both spontaneous POI and those situations in which POI derives from iatrogenic interventions such as radiation therapy, chemotherapy, or surgery. Women with POI may

display established premature menopause or present with intermittent residual ovarian function[4]. The premature hormonal deficiency may be of unknown origin or may be the result of several etiologies, including genetic, autoimmune, metabolic, and infective causes, which lead to ovarian follicular dysfunction or depletion of functional primordial follicles[5] . Spontaneous early menopause affects approximately another 5% of women between ages 40 and 45 years[6] . Moreover, even though the rate of bilateral oophorectomies routinely performed at the time of hysterectomy is declining, a significantly high number of women still enter menopause earlier due to bilateral oophorectomy performed for treatment of ovarian pathology or for prophylactic purpose in women genetically predisposed to breast and ovarian cancer[7] . The percentage of cancer survivors has also increased over time because of improved success in the treatment of cancer in children, adolescents, and reproductive-age women[8] . Therefore, early hormonal deprivation occurs in a large number of women and the short-term and long-term consequences are variable, depending mainly on age at onset and type of POI[9,10]. Importantly, these consequences may include the burden of infertility and the management of fertility preservation[11]. POI is usually diagnosed when two follicle stimulating hormone levels in the menopausal range (>30 U/l), at least 1 month apart in the setting of 4–6 months of amenorrhea, are documented[12]. A timely diagnosis and a tailored hormonal treatment at least until the average age at natural menopause occurring around 50 years are mandatory to relieve menopausal symptoms, and to prevent osteoporosis, cardiovascular risks, and neurocognitive disorders[13] and the increased risk of overall mortality in women with early experience of menopause[14]. On the other hand, POI requires adequate counseling at multiple levels, including psychosocial and sexual consequences, because there is an acceleration of the aging process. Indeed, hormonal replacement is not always entirely able to relieve the multitude of implications for women who have to move forward with their own lives in a POI state[15].

Cytosol estrogen and progesterone receptors are present in many organs including the breasts, endometrium, myometrium, cervix, fallopian tubes and ovaries. The ovaries are not only a source of estrogen and progesterone but they appear to be targets for these hormones[16,17]. Estrogen is considered a primary culprit in the development of ovarian cancer as 70% of ovarian cancers express estrogen receptors (ERs), whereas progesterone and itsreceptor are protective against ovarian cancer[18,19]. In patients with cancers of the breast and endometrium the relationship between tumor estrogen and progesterone receptor (PR) levels and prognosis is well documented. However, the clinical significance of ER and PR content in ovarian carcinomas has not been well established[16,20].Anti-Müllerian hormone (AMH), also known as Müllerian inhibiting substance (MIS) or factor (MIF), has well defined roles in male sex differentiation. Across the female reproductive lifespan the role of AMH has, however, only more recently come to light. AMH is produced by granulosa cells (GCs) in small, growing ovarian follicles, and plays an important role in folliculogenesis. AMH correlates to functional ovarian reserve, and is, therefore, used as a diagnostic and prognostic marker in infertility and in reproductive disorders like polycystic ovary syndrome (PCOS) [21], and primary ovarian insufficiency (POI) [22]. Understanding AMH actions may, therefore, provide insights into follicular development under normal as well as pathophysiological conditions.

Recent studies have indicated that follicular growth is regulated by subtle interactions between gonadotropins (FSH and LH) and local factors produced by the theca and granulosa cells [23]. FSH receptors are expressed in granulosa cells at the primary follicle stage, and they are required for follicular development into the pre-antral stage [24]. FSH activity also increased the primordial pool and enhanced the early follicle stock [25]. LH triggers granulosa wall dissociation and cumulus expansion as well as oocyte nuclear maturation [23].

Materials and Method

Study population and sample collection: The Women included in the present study were gathered from those attending Obstetrics and Gynecology Clinic in Kalar General Hospital, Kalar. The study conducted during the period from June 2019 to January 2020 and total of 60 POF women and 30 apparently healthy matched were included in the study. In this study, the eligibility criteria for POF cases included: (1) under 40 years of age at the first time of diagnosis; (2) amenorrhea for at least 4 months; (3) an increased FSH level >25 IU/L on two occasions >4 weeks apart; (4) patients with known causes of POF (such as karyotypic abnormalities, ovarian surgery, and autoimmune diseases etc.) were excluded. The eligibility criteria for the controls included: (1) healthy women with regular menstrual cycles; (2) without hormonal therapy in the last six months; (3)

without endocrine system diseases, such as polycystic ovary syndrome, thyroid, and hyperprolactinemia etc. Peripheral blood of patients was collected at the time of interview with a structured questionnaire. Venous blood of patient women was collected so that the control . The blood was centrifuged immediately at 3000 r/min for 10 min, and the serum was collected in a polypropylene tube. The samples were stored at 80 C for further chemical analysis and hormone measurement.

Biochemical analysis: The serum progesterone receptors (PRs), estrogen receptors (ERs), Lulilizing hormones (LH), Follicle stimulating hormones (FSH) and Anti mullerian hormones (AMH) progesterone(PRG), estradiol (E2), levels were measured by an automated Roche Modular Analytics E411 immunoassay system (Roche Diagnostics, Mannheim, Germany). Inter and intra-assay coefficient of variations (CVs) for all the tested hormones was less than 10%.

Statistical analysis: The obtained data were analyzed using IBM SPSS statistical package (version 20). Student's t test was applied to calculate significance of differences between patients and controls groups.

Results

Determination the serum progesterone and estrogen receptors: The results of the present study showed significant elevation (P<0.05) in the mean serum level of progesterone receptor in women with POI (4.14±0.42 ng/ml), when compared to control group (2.44±0.33 ng/ml). The serum level of estradiol receptor demonstrated significant elevation in POI cases (4969.92±271.51 pg/ml),when compared to control group (551.17±59.91 pg/ml), Table (1) .

Table (1): Serum progesterone and estrogen receptors in patient cases and controls

Parameter	Patient			Control			P
	Mean±Se	Max	Min	Mean±Se	Max	Min	
PRs ng/ml	4.14±0.42	13.27	0.11	2.44±0.33	8.32	0.15	0.001
ERs pg/ml	4969.92±271.51	8000	360	551.17±59.9	1198	50	0.003

Determination the serum LH, FSH and AMH: The LH and FSH mean serum levels were significantly (P<0.05) higher in women with POI,(43.36 ±3.01, 62.15±3.98 mIu/ml) as compared to controls (6.06±0.40, 6.00±0.31 mIu/ml,) respectively. However, AMH mean serum level (0.16±0.03 ng/ml) was significantly (P<0.05) lower in women with POI than that in controls (2.72 ±0.16), Table (2).

Table (2): Serum LH,FSH and AMH in patient cases and controls

Parameter	Patient			Control			P
	Mean±Se	Max	Min	Mean±Se	Max	Min	
LH mIu/ml	43.36 ±3.01	100.87	10.23	6.06±0.40	9.79	3.12	S
FSH mIu/ml	62.15±3.98	181.32	22.28	6.00±0.31	11.15	2.97	S
AMH ng\ml	0.16±0.03	0.91	0.01	2.72±0.16	4.55	1.29	S

Determination the serum progesterone and estradiol: Both Estradiol and progesterone mean serum values were significantly (P<0.05) lower in women with POI (8.75±0.75 pg/ml, 0.23±0.03 ng/ml) than in controls (56.06±4.11 pg/ml, 0.60±0.04 ng/ml) respectively, Table (3).

Table (3): Serum progesterone and estradiolin patient cases & cotrole

Parameter	Patient			Control			P
	Mean±Se	Max	Min	Mean±Se	Max	Min	
Estrogen pg\ml	8.75±0.75	19.99	0.32	56.06±4.11	102.11	22.36	0.002
Pregesterone ng\ml	0.23±0.03	0.95	0.01	0.60±0.04	0.99	0.24	0.003

Discussion

In the present study the mean serum level of progesterone (PR) and estradiol receptor (ER) was significantly higher in women with POI as compared to controls. This result was conflicting with the result of Kalpokas, Irene, et al[26]. The high levels of progesterone (PR) and estradiol receptors (ER) may be attributed to low serum levels of progesterone and estradiol which were as a result of ovarian dysfunction to produce this hormones. Additionally, the present study indicated a higher significant serum levels of FSH and LH in women with POI than in normal controls. Thus high serum levels of FSH and LH in clinical settings must take in consideration POI as the underlying aetiology. Reduced serum level of AMH in women added another tool for the diagnosis of POI. The result of present study was in agreement with the finding reported by YE, Xiaoqing, et al[27]. The high levels of LH and FSH may be as a result of loss the negative feedback inhibition that induced by progesterone and estradiol hormones.

The mean value of serum progesterone showed lower significant difference in POI cases when compared with healthy control. The present was in agreement with that reported by Czyzyk, Adam, et al[28] and Bemardi, F., et al.[29]. The low serum levels of progesterone and estradiol may be attributed to failure of the ovary to produce them.

Conclusions

Women with POI patient demonstrated significantly high mean serum levels of progesterone and estrogen receptors than healthy control, suggesting possibility of their use as biomarkers for the diagnosis of POI.

The Predictive Value of Osteocalcin, Granulin, Cathepsin K and Some Other Biomarkers in Women with Premature Ovarian Failure

Mahmood Khalil Ibraheem[1], Mutazsabahahmied[2], Firas Shawqi Algburi[3], Amina Hamed Alobaidi[4]

[1]Clinical Biochemistry Specialist, Tikrit University College of Medicine, Tikrit Iraq, [2]Assistant Professor, Tikrit University College of Medicine, Tikrit Iraq, [3]Assistant Professor, Tikrit University College of Science, Tikrit Iraq, [4]Assistant Professor, Kirkuk University College of Veterinary Medicine, Kirkuk

Abstract

Background: Premature ovarian failure (POF), often and misleadingly referred to as 'premature menopause', is defined as a loss of ovarian activity before the age of 40 years and is characterized by irregular or absent periods and reduced fertility. Symptoms include those associated with the natural menopause (night sweats and vaginal dryness), and with the long-term adverse effects of estrogen deficiency (osteoporosis and cardiovascular disease): the latter is believed to explain the shorter life expectancy associated with POF.

Aim: To determinethe predictive value of serum osteocalcin(OC), granulin(GRN), cathepsin k (CTK), vitamin D, parathyroid hormones (PTH), calcium and phosphrus as biomarkers for POF.

Method: Sixty (60) women with idiopathic POF with thirty (30) women as control groups were included in the study. Baseline investigation in all subjects included serum Osteocalcin(OC), granulin(GRN), cathepsin k (CTK), vitamin D, parathyroid hormones (PTH), calcium and phosphrus levels were estimated using the appropriate assays for each.

Results: The mean serum levels of Osteocalcin, Ganulin,Parathyroid hormones,vitamin D and phosphorus, were significantly higher in women with POF,when compared to healthy controls (P=<0.05). However, mean serum levels of cathepsin k and calcium in POF group were non significant differences,when compared to healthy controls.

Conclusion: Osteocalcin and granulin serum levels may be used as new biomarker for the diagnosis of premature ovarian failure.

Introduction

Premature Ovarian Insufficiency (POI) can be spontaneous or iatrogenic and is defined as loss of ovarian function with development of hypergonadotropic hypogonadism in women under the age of 40 years [(1)]. Spontaneous POI affects approximately 1% of women and is associated with genetic defects, autoimmune disorders, environmental factors and infections, but is most commonly idiopathic [(2,3)]. Iatrogenic POI can occur secondary to surgical intervention (E.g. bilateral oophorectomy), chemotherapy and/or radiotherapy [(2,4)]. The effects of oestrogen deficiency include menopausal symptoms such as: vasomotor symptoms, insomnia, mood lability, and vulvo-vaginal atrophy. Longer-term consequences of POI include an increased risk of cardiovascular disease and mortality, accelerated cognitive impairment, infertility and osteoporosis [(2,4–6)].

Osteocalcin (OC), a bone-specific protein synthesized by the osteoblasts in bone, is the major non-collagen protein in the bone matrix. It has a molecular weight of 5,800 Da and contains 49 amino acids, including 3 gamma carboxyl glutamic acid residues that facilitate the binding of OC to hydroxyapatite in bone . The serum OC level, a sensitive marker of bone production, is associated

with a high bone turnover rate and decreased BMD, and correlates well with histomorphometric indices of bone formation[7]. Granulins are a large family of disulfide-rich proteins with diverse biological functions including wound healing, cell growth and proliferation modulation, and angiogenesis[8].Cathepsin K is a papain-like cysteine protease member of the cathepsin family of lysosomal proteases, a family categorized as consisting of cysteine (cathepsins B, C, F, H, K, L, O, S, V, X, and W), aspartate (cathepsins D and E), or serine (cathepsins A and G) proteases depending on the active site amino acid which mediates each member's catalytic activity[9]. An important aspect of cathepsin biology is based on their cellular localization. While cathepsins have greatest activity in acidic environments such as occurs along the endosomal lysosomal continuum, cysteine cathepsins secretion into the extracellular space has also been shown to occur under normal physiologic conditions including skeletal remodeling, wound repair, and prohormone processing[10] .

Vitamin D is synthesized from 7-dehydrocholesterol in the skin via UV-B radiation from the sun. This is an inactive form of vitamin D and requires two enzymatic hydroxylation reactions before activation. These are 25-hydroxylation and 1-a-hydroxylation [11]. While the first reaction takes place mainly in the liver with 25-hydroxylase, the second one occurs primarily in the kidneys with 1-a-hydroxylase (1,25-dihydroxyvitamin D [1,25(OH)2D3]) . This form of vitamin D has a high affinity for binding to vitamin D receptors in target tissue [12]. Renal 1-a-hydroxylase enzyme works under the control of sex hormones and endocrine factors [13]. Vitamin D is a major regulator of calcium phosphorus homeostasis and bone health. Recently, a number of non classical target organs including reproductive ones have been defined for vitamin D. This compilation study explores the potential effects of vitamin D on female reproductive functions. Vitamin D receptors are present in various tissue such as the immune system, endocrine system, and reproductive system [13]. vitamin D receptors are present in both the cytoplasm or nucleus of granulosa cells in ovaries [14]. The presence of vitamin D receptors in female reproductive tissue suggests that vitamin D may have a role in female reproductive functions.

Patient and Method

Study population and sample collection: The Women included in the present study were gathered from those attending Obstetrics and Gynecology Clinic in Kalar General Hospital, Kalar. The study conducted during the period from June 2019 to January 2020 and total of 60 POF women and 30 apparently healthy matched were included in the study.In this study, the eligibility criteria for POF cases included: (1) under 40 years of age at the first time of diagnosis; (2) amenorrhea for at least 4 months; (3) an increased FSH level >25 IU/L on two occasions >4 weeks apart; (4) patients with known causes of POF (such as karyotypic abnormalities, ovarian surgery, and autoimmune diseases etc.) were excluded. The eligibility criteria for the controls included: (1) healthy women with regular menstrual cycles; (2) without hormonal therapy in the last six months; (3) without endocrine system diseases, such as polycystic ovary syndrome, thyroid, and hyperprolactinemia etc. Peripheral blood of patients was collected at the time of interview with a structured questionnaire. Venous blood of patient women was collected so that the control . The blood was centrifuged immediately at 3000 r/min for 10 min, and the serum was collected in a polypropylene tube. The samples were stored at 80 C for further chemical analysis and hormone measurement.

Biochemical analysis: The serum osteocalcin, granulin, cathepsin k,vitamin D and PTH levels were measured by an automated Roche Modular Analytics E411 immunoassay system (Roche Diagnostics, Mannheim, Germany). Inter and intra-assay coefficient of variations (CVs) for all the tested hormones was less than 10%. Total calcium and phosphorus,were determined by Roche Cobas C111 Automatic Biochem Station (Roche Diagnostics, Germany).

Statistical analysis: The obtained data were analyzed using IBM SPSS statistical package (version 20). Student's t test was applied to calculate significance of differences between patients and controls groups.

Results

Determination the serum osteocalcin, granulin and cathepsin k: Mean serum level of osteocalcininpatient (47.35± 5.35 ng/ml) was significantly elevated (P=0.001)as compared with the concentration in the normal controls (17.21± 3.07 ng/ml). However, the mean serum level of Cathepsin K in patient group (0.27± 0.05 ng/ml) was not significantly (P=0.69) differ from that in control group (0.24± 0.07 ng/ml). While,a significant elevation (P=0.002)in the mean serum level of Granulin in patients (7.87± 0.53ng/ml) than in controls (5.44± 0.56 ng/ml), Table (1).

Table (1): Serum Biochemical hormones in patient cases & control

Parameter	Patient			Control			P
	Mean±Se	Min	Max	Mean±Se	Min	Max	
Osteocalcin ng\ml	47.35± 5.35	0.54	130.98	17.21± 3.07	0.54	60.21	00.001
Cathepsin K ng\ml	0.27± 0.05	0.01	1.61	0.24± 0.07	0.02	2.16	0.691
Granulin ng\ml	7.87± 0.53	2.55	20.00	5.44± 0.56	1.80	16.25	0.002

Determination the serum PTH, vitamin D,calcium and phosphorus: The Mean serum levels of parathyroid hormones and vitamin D were significantly lower (P<0.01) in patient (35.42±1.34,12.43±0.90 ng/ml), when compared with controls (46.53±1.77, 20.88±1.99 ng/ml) respectively. While the mean serum level of calcium showed a nonsignificant (P>0.05) in patient cases (9.63±0.07), when compared with control group (9.85±0.09), while the serum level of phosphorus demonstrated significant elevation (P=0.001),in patient cases (1.47±0.02), when compared with control group (1.34±0.02), Table (2) .

Table (2) : Serum bone hormones and maniralin patient cases & controle

Parameter	Patient			Control			P
	Mean±Se	Max	Min	Mean±Se	Max	Min	
PTH ng/ml	35.42±1.34	56.98	15.16	46.53±1.77	62.43	28.69	0.001
Vitamin D ng/ml	12.43±0.90	33.12	3.08	20.88±1.99	41.21	5.36	0.003
Calcium mg/dl	9.63±0.07	10.98	8.22	9.85±0.09	10.73	8.81	0.06
Phosphurse mmol/l	1.47±0.02	1.74	1.22	1.34±0.02	1.53	1.16	0.001

Discussion

In the present study, the mean serum osteocalcin level showed a statistically significant increase in women with POI when compared with apparently healthy control. This finding agreed the study of Singh, Sudhir; etal[15]. Additionally, the mean serum granulin level in POI cases was significantly increased in women with POF. This result in disagreement with that reported by Kan, Ozgur;etal[16]. While the mean serum value of cathepsin k did not shows a significant difference between patients and controls group.

Womens with POF show significant mean serum level of parathyroid hormones than in controls. In addition, VitD deficiency to be significantly more prevalent among POI patients than in controls. as well as the levels of phosphorus showing significantly highermean serum value in women with POI than in controls group. However, calcium mean serum level was not significantly different in women with POI as compared to controls group. This result in contrast with that reported by Ersoy, Ebru, et al [17]as they found no significant difference between Caucasian women POI (n=48) as compared to Caucasian women as controls group.

The present study shows no significant difference in the mean serum levels of vitD, PTH, phosphorus and calcium in women with POI as compared with controls. However, Kurabayashi, etal[18], reported a significant difference in serum PTH levels and non significant in the levels of serum calcium and phosphorus. Their finding was in agreement with the levels of PTH and conflicting with the levels of calcium and phosphorus when compared to controls group.

Conclusions

Women with POI demonstrated significantly higher serum osteocalcin and granulin level than healthy control, suggesting their use as biomarker for the diagnosis premature ovrian insufficiency .

Conflict of Interest: Nil

Abstract

Endometrial carcinoma is the second most common gynecologic cancer worldwide. Hyperplasia is a precursor to endometrioid adenocarcinoma. There are few studies on the association of HPV with endometrial adenocarcinoma.

Aim of the Study: To determine the relation of HPV with premalignant and malignant endometrial lesions.

Patients and Method: This study achieved on a total number of 90 patients with histopathological examination revealing endometrial hyperplasia in 30 patient, endometrial carcinoma in 30 patient in addition to 30 cases who underwent hystrectomy, for all patients detection of HR-HPV done by RT-PCR.

Results: The HR-HPV positivity was recorded in 23 patients. For the studied cases with endometrial carcinoma, endometrial hyperplasia and controls the positivity rates were about (16.7%), (36.7%) and (23.3%) respectively. Highest rate of HR-HPV positivity for the studied patients was found in the age group (45-49). Highest rate of HR-HPV positivity in cases with endometrial carcinoma was reported in older age groups [(45-49) and (50-54)], compared to endometrial hyperplasia and controls [(40-44) and (45-49)]. The HR-HPV positivity was most frequently observed in cases with well-differentiated (22.2%). Higher HR-HPV positivity rate was reported in the hyperplasia without atypia.

Conclusion: No role of HR-HPV in the pathogenesis of endometrial carcinoma.

Keywords: *HPV, endometrial carcinoma, hyperplasia.*

Introduction

Endometrial carcinoma is the most common gynecologic cancer in high-income countries and the second most common gynecologic cancer worldwide when both high and low-income countries are considered[(1)]. In Iraq although it is not within the top ten cancers and it account for 0.56% of total malignant tumor[(2)]. Endometrial cancer is often detectable in the early stages due to the nature of the disease with the 5-year survival rate of 85-91%. About 73% of patients with endometrial cancer are diagnosed in stage I. It is, therefore, very important to identify risk factors followed by primary diagnostic interventions to modify the factors effective on cancer[(3-8)]. Human papilloma virus is one of the most obvious risk factors for cancer[(9)]. Since its recognition as the cause of cervical cancer, this infectious agent has been the focus of intensive researches[(10)].Human papilloma virus is the most common sexually transmitted infection worldwide. It is also the causative agent for 1/3 of all the viral induced tumors and responsible for (5%) of human cancers[(11)]. Human papilloma virus is subdivided into two major

subgroups, namely the low-risk HPVs which are mainly associated with development of warts and benign lesions and high-risk HPVs (e.g 16, 18, 31, 33, 45, 51, 52, 56, 58, 59, 68, 73 & 82) which are considered the main drivers of high-grade lesions and cancers"[12,13,14].

Material and Method

This case-controlled observational study achieved during the period from January 2018 to January 2020 through which a total number of 90 patients were recuruited between 30-71 years of age, who were admitted to the department of Gynecology and Obstetrics in Azadi teaching hospital and private hospitals in Kirkuk city for whom hystrectomy was done for various indications after full clinical assessment with histopathological examination of the hystrectomy specimens and were divided into three groups according to the results of the histopathology consisting of30 patints with endometrial hyperplasia,30 patients with endometrial carcinomain addition to 30 cases with normal endometrium who underwent hystrectomy for catastrophic obstetricalemergencies or for other benign conditions related to tubes, ovaries and uterine corpus like uterine prolapse and leiomyomasas a control group. For all the cases a full history was taken, general and pelvic examination was done, Pap smear was performed in addition to the routine laboratory investigations prior to surgery. Patients with previous history of malignant disease involving the genetal tract or history of vulvar, vaginal or cervical HPV related lesions, intraepithelial neoplasia and carcinoma or abnormal pap smear results were excluded from the study.

Tissue sections were obtained from these patientsbiopsy specimens following hystrectomy in the histopathology laboratories. The histopathological types of endometrial carcinoma and endometrial hyperplasia were classified according to WHO classification[17] and the endometrial carcinoma was staged according to FIGO satging system.For the three groupsof endometrial carcinoma, hyperplasia and controls the detection of 12 types of HR-HPV DNA (types16, 18, 31, 33, 35,39, 45, 51, 52, 56, 58 & 59) using real time polymerase chain reaction in molecular laboratory was done. The variables were analyzed using stratified chi-square and Fisher's exact tests. A statistical test considered significant when the p-value was ≤ 0.05.

Findings: The clinico-pathological data of the studied cases are summarized in table (1). the studied patients were categorized into nine groups according to the age. The mean age of participants was (53.96) years and the median was (56) years. There was no patient younger than 30 years or older than 71 years.

Most of endometrial carcinomas were in the age groups (65-69) years of age (9 cases), with absence of any cases in the age groups below 39 years while the endometrial hyperplasia cases were mostly distributed between the age groups (40-44), (45-49), (50-54) & (55-59) years .

All of endometrial carcinoma were of endometrioid type either well, moderately or poorly differentiated type. The well-differentiated endometrial carcinoma were presented in(60%) of cases,while moderate & poorly differentiated tumors were present in (33.3%) and (6.7%)of patientswith carcinoma respectively, no any squamous differentiation was denoted in this study.

Of the 30 cases of endometrial hyperplasia, 18 (60%) of cases were hyperplasia without atypia while 12 (40%) of cases were atypical hyperplasia/endometrioid intraepithelial neoplasia as shown in (table 1).

Table 1: Endometrial histology pattern according to the age groups.

Endometrial histology		**30-34**	**35-39**	**40-44**	**45-49**	**50-54**	**55-59**	**60-64**	**65-69**	**70+**	**Total**

Total		**5**	**6**	**12**	**13**	**12**	**15**	**12**	**12**	**3**	**90**

Overall HR-HPV positivity was recorded in 25.6% (in 23 cases) of the patients included in the study. For the studied cases with endometrial carcinoma, endometrial hyperplasia and controls the positivity rates were about (16.7%), (36.7%) and (23.3%) respectively. Although the HR-HPV positivity appear higher in endometrial hyperplasia group but the analysis did not identify any statistically significant difference between the three groups as shown in table (2).

Table 2: Frequency distribution of HR-HPV in studied groups.

Studied Groups	HR-HPV (+) No. (%)	HR-HPV (-) No (%)	Total	X^2	P-value
Endometrial carcinoma	5 (16.7)	25 (83.3)	30	3.2706	0.194894
Endometrial hyperplasia	11 (36.7)	19 (63.3)	30		
Control	7 (23.3)	23 (76.7)	30		
Total	**23 (25.6)**	**67 (74.7)**	**90**		

Table (3) shows the distribution of HR-HPV positive cases in the three groups of endometrial carcinoma, hyperplasia and controls according to the age groups. Overall the highest rate of HR-HPV positivity for the studied patients was found in the age group (45-49). In cases with endometrial carcinoma higher rate of HR-HPV positivity was reported in older age groups[(45-49) and (50-54)], compared to endometrial hyperplasia and controls[(40-44) and (45-49)], however this difference in the distribution of HR-HPV positivity according to age groups in the three studied groups was statistically unsignificant.

Table 3: Distribution of positive HR-HPV cases in different age groups .

*Fisher-exact test. Regarding the association of HR-HPV positivity with the grade (differentiation) of endometrial carcinoma, the HR-HPV positivity was most frequently observed in cases with well-differentiated (22.2%) compared to moderate and poorly-differentiated tumors,however this difference was statistically not significantas shown in table (4).

Table 4: Frequency distribution of HR-HPV positivity in different grades of endometrial carcinoma.

	Grade of differentiation	HR-HPV (+) No. (%)	HR-HPV (-) No (%)	Total No. (%)	X^2	p-value
Endometrial carcinoma	Well-differentiated	4 (22.2%)	14(77.8%)	18 (100)	0.6547	0.418442
	Moderately-differentiated	1 (10%)	9(90)	10 (100)		
	Poorly-differentiated	0 (0.0%)	2(100%)	2 (100)		
Total		**5 (16.7)**	**25 (83.3)**	**30 (100)**		

In the current study 25 patients with endometrial carcinoma were of stage I and 5 patients were of stage II cancer and no cases with stage III and IV carcinoma were reported. In addition our data analysis did not observe any statistically significant differences between HR-HPV positivity and tumor staging as shown in table (5).

Table 5: Frequency distribution of HR-HPV in different stages of endometrial carcinoma.

	Stage (FIGO)	HR-HPV (+) No. (%)	HR-HPV (-) No (%)	Total No. (%)	X^2	p-value
Endometrial carcinoma	I	4 (16)	21 (84)	25 (83.3)	0.048	0 .82658
	II	1 (20)	4 (80)	5 (16.7)		
	III	0 (0.0)	0 (0.0)	0 (0.0)		
	IV	0 (0.0)	0 (0.0)	0 (0.0)		
Total		**5 (16.7)**	**25 (83.3)**	**30 (100)**		

In the correlation of HR-HPV positivity with the type of endometrial hyperplasia, higher HR-HPV positivity rate was reported in the hyperplasia without atypiacompared to cases withatypical hyperplasia/endometrioid intraepithelial neoplasia however it was statistically non siginificantas shown in table (6).

Table 6: Frequency distribution of HR-HPV in different types of endometrial hyperplasia.

	Type of hyperplasia	HR-HPV (+) No. (%)	HR-HPV (-) No (%)	Total No. (%)	X^2	P-value
Endometrial hyperplasia	Hyperplasia without atypia	7 (38.8)	11(61.1)	18 (100)	0.0957	0 .75706
	Atypical hyperplasia/endometrioid intraepithelial neoplasia	4 (33.3)	8 (66.7)	12 (100)		
Total		**11 (36.7)**	**19 (63.3)**	**30 (100)**		

Discussion

In the present study, the mean age for endometrial cancer cases was (57.6 yrs). Which was comparable with those reported worldwide revealing that endometrial carcinoma is usually affectingfemales over fifty years of age[18,19] also consistent with other local study[20].

All the cases of endometrial carcinoma in our study were of endometrioid type with no any squamous differentiation was denoted. It is not clear "whether HPV infections can provide morphological changes in the endometrial glandular type epithelium" as far till now "koilocytic changes" have only been reported in the squamous cell carcinoma, adenosquamous carcinoma or squamoid component of some endometrial carcinomas. Based on these changes, "HPV considered not only a traveler but can also stimulate squamous metaplasia in the endometrium"[21].

Regarding histopathological tumor differentiation (grade), in the present study we found that the most prominent grade among endometrial carcinoma cases wasthe well-differentiated (60%), followed by (33%) and (6.7%) for moderate & poorly differentiated respectively this was comparableto results of studies from other countries that reported well-differentiated carcinoma in

(77%) of cases compared to (21%) and (3%) for moderate and poorly differentiated tumors respectively[22,23]While it was inconsistence with the findings of other national investigator[20] observinga well-differentiated carcinoma in just (3.3%) with (60%), (36.7%) in moderate and poorly-differentiated tumors respectivly. The reason for this discrepancy may be related to the different sample size included in the studies.

Sixity percent of endometrial hyperplasia in the current study were without atypia while 40% were of atypical endometrial hyperplasia/endometrioid intraepithelial neoplasia type.

The correlation between HPV positivity and age groups in our work show overall, the highest rate of HR-HPV positivity for the patients studied was found in the age group (45-49) (30.4 %). In cases of endometrial carcinoma, higher levels of HR-HPV positivity have been identified in older age groups [(45-49) and (50-54)] relative to endometrial hyperplasia and controls [(40-44) and (45-49)], but this disparity in the distribution of HR-HPV positivity by age groups has been recorded, but unfortunately we didn't found any study to compare these datas.

In the current work, HR-HPV was detected in all studied groups including endometrial carcinoma, endometrial hyperplasia and controls, with higher frequency among endometrial hyperplasia (36.7%), and to a lesser extent in the control (23.3%) and endometrial carcinoma (16.7%). These figures are close to those reportedin Japanese and Brazelian women[26]

and comparable with the results of other studies recording low rate of HR-HPV positivity among patients with carcinoma suggesting non-significant association between HR-HPV infection and endometrial carcinoma[27,28,29] and even failure of detection of HR-HPV in endometrial carcinoma group in other studies[30,31,32] .

On the contrary other scientific investigators showed different resultsreporting higher incidence of HR-HPV positivity (63.3%-87.5%) in endometrial carcinoma patients[20, 25]. This discrepancy may be attributed to several factors including the actual methodology such asusing different tissue preparation techniques in these studies like 'frozen section' or'the choice of different detection method for HPV with high false positive results like CISH (chromogenic in situ hybridization) and southern blot hybridization analysis'compared with the high-sensitivity detection method that is PCR[33] used in the current study.In addition to the difference in the studied populations in relation to non appraisal risk factors (low socioeconomic status, multiple sexual partners, interaction with other sexually transmitted infection, smoking) andto the different HPV genotype observed among popultions in the different countries. Similarly in a recent study from a neighbour country held by Mohammed et al analyzing the association of HPV16 and 18 with the risk of development of invasive cervical and endometrial carcinoma observed a higher rate of HPV positivity (mainly HPV-18) in cases with endometrial carcinoma (60%) compared to controls (29.4%)[34] again this discripency with our study may be the impact of heterogeneity among the studied groups with regard to age and histological types of endometrial carcinoma and absence of squamous elements (adenocarcinoma with squamous differentiation and squamous cell carcinoma) in any cases of our series.

In the present study although higher HR-HPV positive cases found in endometrial carcinoma with well-differentiated tumors, there was no significant association between HPV positivity and tumor grade. In addition we failed to find any significant association of HPV infection with the progression and stage of the disease. This is consistent with observations of other studies[20,35, 36] finding that the presence of HPV in endometrial neoplasm was unrelated to histopathological differentiation, prognostic features and patient survival.

During the current study a higher HPV positive rate was observed in cases of "endometrial hyperplasia without atypia" (38.8%)compared to "atypical hyperplasia/endometrioid intraepithelial neoplasia" (33.3%)despite that the difference was not statistically significant. Given that HPV infection is speculated to preceed the progressionto cancer, it is intersting that HPV was detected with less frequency in endometrial hyperplasia at risk of progressing to endometrial carcinoma, namely atypical hyperplasia/endometrioid intraepithelial neoplasia, than those not known to bear such development risk, namely hyperplasia without atypia. This clearly means that HPV can not trigger the oncogenic events atthe endometrium through the sequence of"atypical hyperplasia-neoplasia". In other ward we can say that HR-HPV may play a little carcinogenic effectand this needs other factors like "life style, hormonal, genetic, environmental & immune deficient state" for progression into malignancy. Consistently a lowerrate of HR-HPV infection

in"atypical hyperplasia" were reported earlier in other studies[37,38].

Conclusion

In conclusion these findings may suggest a limited or no role of HR-HPV in the pathogenesis of endometrial carcinoma at least those without squamous elements as the columnar epithelium of the endometrium may not be a convenient host for HR-HPV replication, maturation and neoplastic transformation process.

Differences between Bribery and Gratification: A Review of Anti-Corruption Act of Indonesia

Mahrus Ali[1], Al Halim[2], WahyuPriyanka Nata Permana[3]

[1]Senior Lecturer of Criminal Law Department, Faculty of Law Universitas Islam Indonesia and alumni of Diponegoro University, Indonesia, [2]Doctorat Program Student in Law Diponegoro University, Indonesia and a Public Notary, [3]Lecturer of Law of Criminal Procedure Department, Faculty of Law Universitas Islam Indonesia

Abstract

This study analyzes the concepts of bribery and gratification and the distinguishing parameters between them as regulated in several Articles of the Anti-Corruption Law. This involved the application of the normative legal research supported by court decisions to clarify these differences. The results of this study showed that bribery requires a meeting of mind between the bribe givers and bribe recipients which is not found in gratification. The reporting mechanism and the reversal burden of proof do not apply to bribery while Operation Catching Hand does not apply to gratification due to its inability to satisfy the provisions of Article 1 point 19 of the Criminal Procedure Code. Criminal sanctions are also imposed on both the giver and the recipient of a bribe while the act of a giver in gratification is not considered as a criminal offense. The study also found the wrong application of these essential differences in court decisions.

Keywords: *Meeting of mind, reversal burden of proof, caught hand, report mechanism.*

Introduction

Law Number 31 of 1999 and 20 of 2001 concerning Corruption (hereinafter called Anti-corruption Law) regulates 7 types of criminal acts of corruption including those associated with state financial losses, embezzlement in office, bribery, extortion, conflicts of interest in procurement, fraud, and gratification. In comparison with the others, the formulation of bribery offenses in the Anti-Corruption Law is at most regulated in Articles 5, 6, 11, 12 a, b, c, and d as well as Article 13. Moreover, the data released by the Corruption Eradication Commission (KPK) between 2014-2019 shows that 65% of corruption cases in Indonesia are bribery.[1] The Catching Hand (OTT) conducted by the KPK from 2016-2019 totaling 87 times was also all related to bribery.[2]

Corresponding Author:

e-mail: mahrus_ali@uii.ac.id

The Anti-Corruption Law does not provide a specific meaning or clear parameters related to the act of bribery despite its frequent occurrence and regulation in several offenses. This, therefore, affects the handling of bribery cases both by the KPK, the police, the prosecutor's office, and the court.[3] It also shifts the establishment of a legal norm from the legislators to law enforcement by providing them the power to declare an action as a bribe.[4]

This study was, therefore, conducted to explore the general concepts and parameters determining an act as a bribery and to analyze the difference between the concept and gratification. This is necessary due to the fact that the Anti-Corruption Law also prohibits the acceptance of gratuities. Some court decisions related to bribery and gratification cases were also reviewed and the result of this study is considered crucial and important for law enforcement official in applying bribery legal norms while handling corruption cases.

Method

A normative legal research method was used to particularly examine the legal norms on bribery and gratification in the Anti-Corruption Law as promulgated

in Law Number 31 1999 and 20 of 2001 concerning Suppression of Corruption, Indonesia. These provisions were used as the primary source of this study using a statute and conceptual approach. Literature study as well as court decisions were also used to collect data based on the assumption that the essential natures and parameters between bribery and gratification as defined by scholars need to be clearly distinguished. The data were analyzed qualitatively through data reduction by focusing on the Articles of bribery and gratification in the Anti-Corruption Law after which findings were presented and conclusions were drawn.

Results and Discussion

The Nature of Bribery: Bribery is generally defined as 'the abuse of public office for private gain'.[5] It specifically means giving or promising a state administrator or public servant some certain privileges[6] due to the favor obtainable from the position[7] and has also been equated with the positional offense.[8] This study was, however, limited to public positions without the inclusion of the private sector[9] due to the fact that the Anti-Corruption Law does not include bribery in the private sector as a corruption criminal act[10] in line with the 2003 United Nations Convention against Corruption ratified by Indonesia with Law Number 7 of 2006.

The bribery offense in the Anti-Corruption Law is characterized by several natures such as the meeting of mind between the bribe giver and recipient. This means that bribe is not established except the two parties have the will and are aware of the action. This, in economics, requires the activities of supply and demand between them.[11] This means bribery case necessitates the use of Article 55 paragraph (1) of Criminal Code specifically concerning participation to crime (*medeplegen)* that requires two pieces of evidence of intention; intentional cooperation to commit an offense and performance of an offense together committed internationally.[12] It is, therefore, not appropriate to convict only the giver or recipient of a bribe. For example, in the Century Bank scandalous corruption case, the panel of judges convicted Budi Mulia, a former Governor of Central Bank of Indonesia, for participating in the act in a quo case based on Article 55 paragraph (1) of Criminal Code while Boediono, a former Vice President of Indonesia and the senior Governor at the time, was not suspected or even convicted even though the verdict proves that the century bailout decision can only be taken collectively and collegially.

The evil intention to conduct a prohibited act usually happens before a bribe offense is committed through the use of an object such as a gift or promise. The author, however, feels it is inappropriate to describe a gift as a bribery object due to the fact that it is allowed but proposed the use of the term 'something' instead which is further defined as anything of economic value. It is not necessary that the recipient has the bribery object in possession before a case is established as long as such an individual has sufficient control over the item. Promises are not in the form of goods but are generally related to actions of the giver in response to an activity conducted by the recipient. The bribe giver can be anyone including individuals, corporations, public servants, advocates, judges, or even state administrators while the recipients are limited to civil servants, state administrators, advocates, and judges.[13] This is necessary considering the fact that bribe is related to the position of the recipient which is usually public as observed with public servants or state administrators not doing anything in their position or found using their authority or position to conduct some activities.

The prohibited acts conducted by the bribe giver include 'giving or promising something to the public servants or state administrators' (Article 5 paragraph 1 letter a),' giving something to civil servants or state administrators' (Article 5 paragraph 1 letter b), 'giving or promising something to an advocate '(Article 6 paragraph 1 letter a),' giving or promising something to a judge '(Article 6 paragraph 1 letter b)', and 'giving gifts or promises to civil servants keeping in mind the power or authority attached to the position or his position' (Article 13). Meanwhile, the prohibited conduct for the recipients is 'accepting gifts or promises' (Article 5 paragraph 2), 'judges or advocates accepting gifts or promises' (Article 6 paragraph 2), 'public servants or state administrators receiving gifts or promises despite knowing they are provided in order to influence their decisions or actions is contrary to their obligations' (Article 12 letter a), 'public servants or state administrators receiving gifts even though they reasonably suspect the gifts are meant to influence their professional conduct is contrary to their obligations' (Article 12 letter b), 'the judge receiving a gift or promise' (Article 12 letter c), and 'the advocate receiving a gift or promise' (Article 12 letter d). Article 12 letter a focuses on the bribe provided to the civil servants or state administrators to conduct a certain act while letter b emphasizes those provided after the action has been conducted.

The reversal burden of proof does not apply in bribery cases and this means neither the bribe giver nor the recipient is obliged to prove that the gift or promise has nothing to do with the public position of the recipient since it is the responsibility of the public prosecutor.[14] It is, however, possible to have catch hands/ caught operations (OTT) in bribes offenses as observed in KPK[15] where they are implemented in several corruption cases which are almost impossible to solve using conventional method. Even though it is possible to have OTT in bribery offenses, those conducted by KPK do not actually violate the four criteria of being caught red-handed as shown in Article 1 number 19 of Law Number 8 of 1981 concerning the Criminal Procedure Code (KUHAP). The criteria includes arresting a person, while committing a crime, immediately after the crime is committed, third, based on the confirmation of the general public, and the moment an object allegedly used in committing a crime indicates the perpetrator participated or assisted in the process.[16]

In a case of bribery offense, OTT is in the form of a promise to a civil servant or organizer to receive favor based on the position of such an individual contrary to obligations. For example, a defendant promises a judge a sum of Rp. 2 billion to acquit such person in a corruption case, bribery is established when there is an agreement between them. It is important to note that the offense is completed on the day where the agreement was made, assuming March 30, 2020, even though the promise was fulfilled on July 23, 2020, after the defendant has been acquitted by the judge, and KPK implemented OTT against both the defendant and the judge. The four criteria of being caught red-handed in Article 1 number 19 of the Criminal Procedure Code have not been met, therefore, the process is declared as illegal OTT due to the existence of 4 months between the period the offense was committed and OTT was implemented by KPK.

Gratification vs Bribery

Gratification is determined to be an offense in Article 12B of the Anti-Corruption Law formulated to include the following:

1. Every gratification to a civil servant or a state administrator is considered a bribe as long as it relates to the position and contrary to the obligations or duties of such individual with the following conditions:

a. In the amount of IDR 10,000,000.00 (ten million rupiahs) or more with proofs the gratuity is not a bribe made according to the recipient;

b. The value less than IDR 10,000,000.00 (ten million rupiahs) with proofs the bribery is conducted by the public prosecutor.

2. Criminal punishment for civil servants or state administrators as referred to in paragraph (1) is life imprisonment or imprisonment for a minimum of 4 (four) years and a maximum of 20 (twenty) years, and a minimum fine of IDR 200,000,000.00 (two hundred million rupiahs) and a maximum of IDR 1,000,000,000.00 (one billion rupiahs).

This article defines 'gratification' as a gift in the broadest sense including the provision of money, goods, rebates (discounts), commissions, loans without interest, travel tickets, lodging facilities, tourist trips, free medical treatment, and other facilities which are received both domestically and abroad or conducted using electronic or non-electronic means. The acceptance of gratuities by civil servants or state administrators by virtue of their position and against their obligations or duties is known as gratification. There is usually no meeting of mind between the gratuity giver and the public servants or state administrators as the recipients. The existence of a meeting of mind makes the gift a bribe with the gratification objects broadly as previously explained in Article 12B paragraph (1).

The gratuity recipient is obliged to prove the gift received is not a bribe and has nothing to do with the position not contrary to the obligation if the value is IDR. 10,000,000 or more. Such cases also involve provisions or mechanisms of reporting as confirmed by Article 12C paragraph (1), (2), and (3) that the offense in Article 12B paragraph (1) does not apply if the recipient reports the gratification received to the Corruption Eradication Commission (KPK) no later than 30 (thirty) working days from the date where the gratuity is received to determine the gratuity belong to the recipient or the state.

The provision of Article 12C eliminates criminal prosecution against civil servants or State administrators receiving gratuities. It means that acceptance of gratuity itself is an offense but the prosecution process depends on whether or not a report has been filed by the recipient to the KPK no later than 30 working days from the date it was received after which the commission determines either the gratuity belongs to the recipient or the state. Even though the Anti-Corruption Law interprets

gratification broadly, it does not include sexual relations services provided by a person to a public servant or state administrator known as sexual gratification due to its ability to cause problems as well as the impracticality of determining either the action belongs to the recipient or state. Does the inclusion of sexual service in the meaning or form of gratification makes KPK confiscate 'women's goods' as the property of the State and then auction it off? This is, of course, impossible and causes women dignity. Therefore, gratification needs to be limited to the material forms and types.

Another sign of gratuity is the emergence of evil intention precisely after civil servants or state administrators receive a gift because of their position.[17] They are, however, allowed to report such gist within a 30-day work period to avoid being prosecuted based on Catching Hands Operation (OTT). KPK is not authorized to conduct OTT on corruption cases related to the acceptance of gratuities due to the fact that the four criteria of being caught red-handed previously described are not satisfied. For example, a civil servant receives gratuity between April 3 and 4, 2020 and, 30 working days later, the Corruption Eradication Commission is not authorized to conduct OTT due to the provision of Article 12C paragraph (1) and 12B paragraph (1) Anti-Corruption Law which prohibit the KPK to conduct OTT after 30 working days of receiving gratuities because it contradicts the criteria previously explained. To understand more clearly, the following table shows the difference between bribery and gratification:

Table 1: Gratuity vs. Bribery

Element	Gratuity	Bribery
Perpetrators/Actor	Civil servants/State administrators	Public servants/State administrators/individuals/advocates/ corporation/private employees
Meeting of mind	No	Yes
Bad intention	After receiving gratuity	Before a bribe occurs
Reporting mechanism	The provisions/mechanisms of reporting to the KPK apply	The provisions/mechanisms of reporting are not applicable
Reversal burden of the proof	Apply	Not apply
OTT	Impossible	Possible

The data are processed by the authors: In the gratification case of Nur Alam, a former Governor of Southeast Sulawesi, the verdict of the first instance court, appeal, and casation stated that Nur Alam was proven to have received a gratuity considered a bribe from Richcorp International Ltd in the amount of IDR. 40,268,792,850 from illegal grounds and not reported to the KPK within the prescribed time limit. The decision was based on several legal considerations. The money borrowed by the defendant personally from Chen Linzecertainly opened the opportunity for a conflict of interest to the defendant as the Southeast Sulawesi Governor. Besides, sending money to the defendant to buy an insurance policy at AXA Mandiri on behalf of the defendant using his biological children as beneficiaries also proves that the money is not a Chen Linze's investment to advance Southeast Sulawesi but from Richcorp International Ltd for the defendant. In addition, all cancellation/disbursement of the three AXA Mandiri insurance policies on behalf of the defendant has been accommodated in the Non-Customer Giro (GNC) account of IDR 30,481,436,261.00. At the defendant's request, the money was transferred to the account of Timbel Mas Abadi Ltd. gradually with each transaction below the nominal value of IDR 500,000,000 to avoid suspicion from PPATK. Finally, the money in the Sultra Timbel Mas Abadi Ltd. account, at the defendant's request to Bank Mandiri, was also transferred in batches with the value less than IDR 500,000,000 to avoid suspicion from PPATK with the destination account being Untung Anaugi Ltd, Gino Valentino Ltd, and Bososi Pratama Ltd.[18]

According to the researchers, the money received by the defendant was not a gratuity or a bribe and the defendant's actions are purely considered a civil law in the form of investment placements and personal loans. It is strengthened by several facts that investment Agreement No. CI/NA/IA/2010/001 of 19 August 2010 conducted by Richcorp International Ltd and the

defendant in a personal capacity. Provisional Fund Provision Agreement No. PPDS/RC/NA/2010/002 dated August 19, 2010. Moreover, based on the investment agreement and personal loan in the amount of IDR 40,268,792,850, the defendant apparently returned the money to Richcorp International Ltd as observed from these two pieces of evidence. First, evidence of money transfers from Giofedi Rauf to Richcorp International Ltd totaling IDR 15,000,000,000 dated May 30, 2013, IDR 15,000,000,000 dated June 3, 2013, and IDR 10. 750.000.000 dated June 4, 2013. A letter dated June 10, 2013, from Richcorp International Ltd to Geofedi Rauf regarding evidence of receipt of money transferred by the defendant in the amount of IDR. 40,750,229,110. This shows that the defendant returned the money to Richcorp International Ltd before the investigation was conducted by KPK. The money was also returned in accordance with the contents of Investment Agreement No. CI/NA/IA/2010/001 dated August 19, 2010, between Richcorp International Ltd and the defendant is in a personal capacity and Agreement of Temporary Funds Provision No. PPDS/RC/NA/2010/002 dated 19 August 2010.[19] This, therefore, means there is no connection between the defendant's position as the Southeast Sulawesi Governor and transactions. It is important to note that it is only possible to establish gratification as long as it is related to the defendant's position.

Conclusion

Bribery and gratuity are *malversations*. Meanwhile, in bribery, the bribe giver and receiver need to agree to commit a crime before it happens and the existence of the word 'agreed' becomes the basis for the crime imposed on both of them. The Anti-Corruption Law shows the givers can be anybody from any background while the recipients are limited only to certain performers. Moreover, the OTT usually conducted by KPK are all related to bribery cases. It was also discovered that reversal burden of proof and reporting mechanism apply only to gratuities and this means that the recipients have 30 working days after gratification has been received to report to the KPK to avoid criminal prosecution. Failure to report means that the recipient is corrupt.

Study to Assess the Level of Stress among Nursing Students

Mandeep Kaur[1], Kanika Guleria[2], Anisha[3]

[1]Nursing Tutor, Chitkara School of Health Sciences, Chitkara University, Punjab, India, [2]Assistant Professor, Chitkara School of Health Sciences, Chitkara University, Punjab, India, [3]Nursing Tutor, Chitkara School of Health Sciences, Chitkara University, Punjab, India

Abstract

Stress is a state created by amendment in atmosphere that is damaging to the person's equilibrium and is mostly prevalent in nursing students. The study aims to measure the stress level of nursing students. Sample size consisted of 63 nursing students of GNM 1st year and B.Sc.(N) Post basic 1st year chosen by convenience non-probability sampling technique and informed consent were taken from subjects. The UN Management stress tool was used to collect data which was taken from UNO Management Booklet of series. The results of the study has revealed that 97% of GNM 1st year students and 67% of Post Basic B.Sc. Nursing students were in moderate stress. The stress level is high in GNM 1st year students as compare to post basic BSc Nursing 1st year. Mean stress score of Post Basic B.Sc.(N) 1st year and GNM 1st year was 17 ± 2.3 & 23 ± 3.5.

Keywords: *Prevalence, Stress, Nursing Students.*

Introduction

Stress is produced by varying environment. It disturbs the mental balance of any person. Nursing is training is one of the most stressing training. Numerous studies have shown that there are many reasons of stress throughout nursing training. The prevalent sources of stress felt by students and faculty that comprises curriculum requirements, assignments and examinations and combining clinical work with studies.[1]

According to the Oxford University, it is a state of affair involving on physical or mental energy. We can define stress as private state that is produced by physical requirements on the body or by atmosphere and social state of affairs that are evaluated as probably harmful, not under control or surpassing our resources for coping. Seyle has defined stress as excessive burning of energy resources.

Stress is a big problem in the society. 75% of bodily disease are said to be due to stress. There are many stressors like transitions in life, money problems, pressure of day-to-day life, no leisure time, problems in relationships and domestic problems. Nursing students face both academic as well as professional stress during their training period.[2] Academic stress is that stress which is faced by students during academic period. One study suggested that stress is linked with the type of institution in which the nursing student studies. For instance, Curriculum pattern of private college can be different from Government nursing College.[3] Professional stress is that which is caused during job.

According to "UN Management Booklet" stress is of three types:

1. Basic stress: It is a minor stress which include in day-to-day situation that tension, frustration, anger & irritation.
2. Cumulative stress: It is a result of strain occurs too often, more severe and stays for longer period.
3. Traumatic stress: This stress threatens physically or psychologically.

Stress can have a positive and negative aspect, when it is positive it acts as motivator for growth but when it

is negative, it causes illness. Academic stress becomes serious mental health problem. Nursing students are important and beneficial human assists. Detection ofstress is extremely important as it can be the reason of low productivity, decreased quality of life and suicidal thoughts which are due to examination, assignments submission, and assessment.

According to study done on nursing students in public university, more than 50% subjects had stress symptoms. This stress decreases quality of life of students.[4]

The study conducted on 455 nursing students in Nursing college, Brazil revealed that 64% of students were having stress[5].

Study done at PGIMER Chandigarh on 43 Nursing students, revealed that the moderate stress level was 99.2 among 5 students, mild stress 72.33 among 21 students and no stress is 46.42 among 17 students. 11.62% subjects experienced moderate stress and 48.83% experienced mild stress, 39.53% experienced no stress.[6]

According to, one more study done at Seth Medical College to assess level of stress among medical students. Results of their study has shown that majority of students perceived 73% stress and high stress level was stress found in 2nd year rather in 1st or 3rd year.[7]

In the present scenario, stress has become a big problem especially among students. This condition can be witnessed among nursing students, so researcher has conducted a study to find out the stress level of nursing students of Nursing college of Punjab.

Subjects and Method

A descriptive research design was adopted for the study. Study was conducted at Kular College of Nursing, Kishangarh. The sample of 63 students was chosen by convenience sampling technique. All the nursing students who were ready to give informed consent were included in the study. Those who didnot give informed consent or who were not accessible at the time of compilation of data were excluded from the study. This study was approved by Advisory Committee of Nursing College and participants were included in the study after taking permission from Principal of College and students were assured of confidentiality. A structured Performa containing socio demographic data including the basic information such as age, sex, marital status, nursing course, subjects was distributed to the participants. A standard questionnaire tool was taken from UNO Management of Stress *Management*: In this tool, 10 questions were given to assess stress and it had maximum score of 30 and minimum score of 15. Score upto 15 considered normal, 15 – 25 considered Moderate Stress level and 25 – 30 considered Severe Stress level. The descriptive and inferential statistical measures used for analysis for identifying the result of study.

Results

Ninety-seven percent of the study population was Female and three percent were Male. Maximum respondents were from the rural background. 75% from rural area and 25% from urban area. Only 8%of subjects were married and rest 92% were unmarried. The subjects of 18 years of age or less than 18 years had more stress than subjects of morethan 18-years-of-age. (Table 1).

Table 1: Socio demographic variables of the subjects from both the groups. N=63

Demographic Variables	N	%
Age		
<18 or 18	20	32%
19-22	24	38%
23 or >23	19	30%
Marital status		
Married	6	8%
Unmarried	57	92%
Sex		
Male	2	3%
Female	61	97%
Resident		
Rural	47	75%
Urban	16	25%
Classes		
GNM	36	57%
Post Basic B.Sc.(N)	27	43%

Table 1 depicted that, more than half of the subjects (38%) were from age group of 19-22. Majority of the females (97%) were unmarried (92%). Majority of the subjects (75%) were from rural area. More than half of the subjects (57%) were from GNM 1st year.

Table 2: Mean score of stress levels among GNM 1st year and B.Sc (N) Post basic 1st year students

Classes	GNM 1st year	Post Basic B.Sc. Nursing 1st year
Mild stress	1 (3%)	9 (33%)
Moderate stress	35 (97%)	18 (67%)
Mean ± SD	23 ± 3.5	17 ± 2.3

Table 2 depicted that moderate stress (97%) was more in GNM 1st year students and rest of the subjects had mild stress with a mean score of 23 ± 3.5 whereas in B.Sc (N) Post Basic 1st Year, more than half of subjects (67%) had moderate stress and rest of the subjects had mild stress with a mean score 17 ± 2.3. The G.N.M 1st year subjects were having more stress than B.Sc. (N) Post Basic 1st Year as indicated by the higher mean score.

Prevalence of Stress: About 97% GNM 1st year students and 67% B.Sc (N) Post basic 1st year students had Moderate stress level. Mean stress score of GNM 1st year students came out 23 ± 3.5 and Mean stress score of Post basic 1st year students was 17 ± 2.3. The finding shows that the level of moderate stress is higher than mild stress & there is no case of severe stress. (Table 2 & Figure 1).

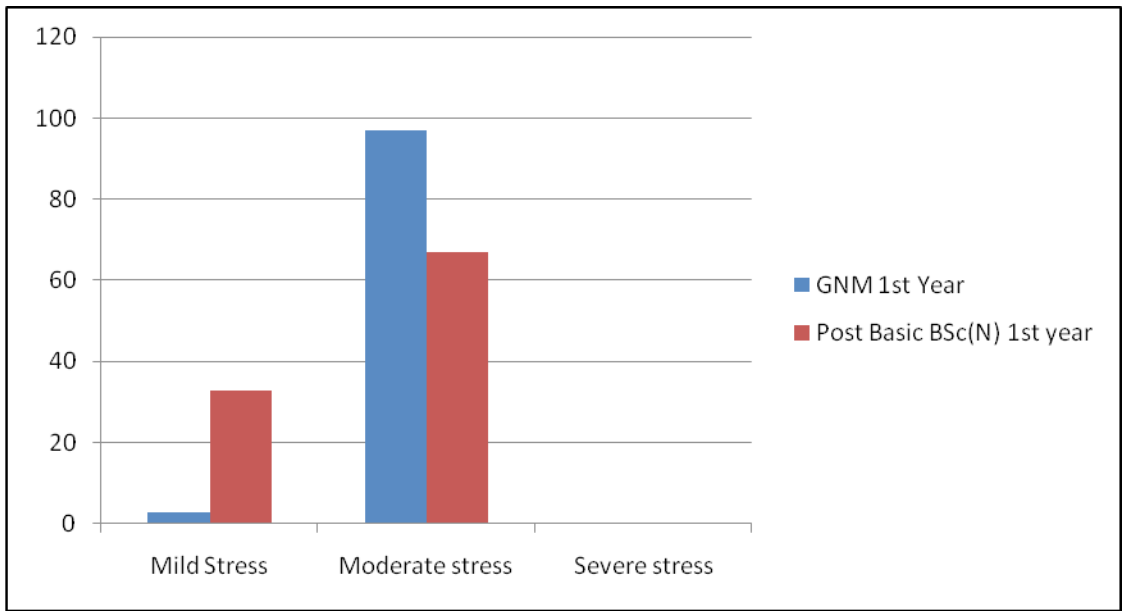

Figure 1: Percentage distribution of stress level among both groups.

Figure 1 depicts that 97% subjects of GNM 1st year and 67% subjects of Post basic B.Sc.(N) 1st year had moderate stress. And 3% subjects of GNM 1st year and 33% of Post Basic BSc (N) 1st year had mild stress. None of the subjects has severe stress.

Table 3: Association between stress scores and selected demographic variables.

Demographic variables	Mild stress	Moderate stress	df	Table value	Chi square	p-value
Age						
<18 or 18	1	19				
19-22	7	17	2	5.99	5.3536S	0.0687
23 or >23	2	17				
Marital status						
Married	4	2	1	3.84	12.812s	0.002
Unmarried	6	51				

Demographic variables	Mild stress	Moderate stress	df	Table value	Chi square	p-value
Sex						
Male	1	1	1	3.84	1.8015^{NS}	0.1794
Female	9	52				
Resident						
Rural	9	38	1	3.84	1.4873^{NS}	0.2226
Urban	1	15				
Classes						
GNM	1	35	1	3.84	10.7873^{S}	0.0009
Post Basic B.Sc.(N)	9	18				

Table 3 shows that the association between stress scores and socio demographic variable such as age, marital status and classes found significant, as calculated value is greater than tabulated value at the p level of significance < 0.05. It means stress scores were associated with age and marital status. And the association between stress scores and socio demographic variables such as sex and gender found non-significant, as calculated value is less than tabulated value at the p level of significance <0.05.

Discussion

The present study showed that level of moderate stress was higher than mild stress. The level of moderate stress among 35 students of GNM 1St year was 97% percentage and 67% among 18 students of B.Sc (N) Post basic 1st year. According to one study conducted among nursing students in Kathmandu university to assess the academic stress, the result came out with 75% students with academic stress [8].Similar result was found in one study done on Nursing workers. It was a comparative study to determine job related stress, stress reaction, coping strategies adopted by nursing personnel working in critical and non-critical unit of selected hospital of Delhi. It was found that percentage of moderate stress was higher that is 59.65% than mild stress 22.81%. Most of them felt troubles in participation in social life due to institute's timings, living away from home, lack of time for self- study, strict rules and regulation in the hospital, unable to get leisure time for recreation. The finding of the research showed that the moderate stress was more in the age group of 18 or less than 18 (95%) as compare to other age group. Similar result was found in one study done on nursing students of B.Sc Nursing 1st year at PGI Chandigarh. The results of the study has shown that the stress level was greater in the age group of 17 – 22 years & level of moderate stress was higher than mild stress. Mean of moderate stress is 99.2 & 72.33 in mild stress.

Conclusion

Stress has become a never ending, continuous & prevalent condition in today's world. Preset generation is marked as generation of stress. Everyone experiences various forms of stress in their lives. Stress has become very common among the students. In the present research, attempt was made to determine the stress among nursing students in Nursing College, Punjab following a descriptive design. This study has tried to assess the mental well-being or the lack thereof, of the students undergoing nursing training. The fact that these students are finding the subjects difficult, living in hostels, doing shift duties in hospitals, academic workload is reflected in the significantly higher incidence of stress that they experience, as compared to the general population. We suggest that an induction program at the start of the nursing course, and positive mental health training can go a long way toward reducing strain of nursing students and can provide betterment to their professional and personal well-being.

Acknowledgement: The researchers would like to express their special thanks to Mrs Aditya Sharma, Former Principal of Kular College of Nursing for permitting us to perform the study and all the participants of this study for their valuable responses.

Financial Support & Sponsorship: Nil

Conflict of Interest: There are no conflict of interest

Ethical Clearance: Taken from the ethical and research committee of Kular College of Nursing.

Methodical Learning on Organ Donation: Effect on Students Knowledge and Attitude

Maninder Singh[1], Manpreet Kaur Grewal[1], Amanpreet Kaur[1], Yamini Chopra[2], Aarti Bhatt[2], Tenzin Choden[2], Manisha Sharma[2]

[1]Assitant Professor, [2]B.Sc Nursing 4th Year Student, Chitkara School of Health Sciences, Chitkara University, Punjab, India

Abstract

Introduction: Organ donation provides the recipient with a second chance to live. Inappropriate knowledge and attitude of individuals to organ donation are one of the most important barriers for organ donation.

Aims and Objectives: To determine the effectiveness of structured teaching program on knowledge and attitude regarding organ donation among students.

Study Design: Pre-experimental one group pre-test and post-test.

Study Variables: Age, Religion, Habitat, Family type,Education stream, and Information source.

Result and Discussion: It was found that after a structured teaching program knowledge level of students in post-test was increased that is 66% adequate knowledge whereas 34% of participants have moderate knowledge. Also, in pre-test 89% of the student had poor attitude and 79% student had satisfactory attitude in post-test. Significant association between the level scoreof knowledge with an information source had been found.

Conclusion: In the present study, a marked increase in knowledge and change in the attitude level of the students has been observed during the post test.

Keywords: *Organ donation, knowledge, attitude.*

Introduction

Organ Donation is the caring demonstration of giving one's organs to someone else, who is in critical need of those organs. It is characterized by the WHO as "giving human cells, tissues, and organs proposed for human applications". Giving an organ can prompt sparing as well as improving the quality of life of someone else. Shockingly, the quantity of individuals that need an organ incredibly outperforms the quantity of genuine givers.[1]

In the world, India's organ donation rate is the lowest rate that is 0.86 per million. In India, 500,000 individuals need organ transplantation every year and a large number of them pass on because of an absence of organs accessible for transplantation. [2] Lack of mindfulness alongside myths and misguided judgments adds to the low level of organ donation. Young adults address the inevitable destiny of society and effect family members and partners. A bit of good data on the young adults in this issue, not just method a constructive faculty disposition towards organ donation yet it can in like manner be the choosing part for supporting gifts when faced with the death of a relative.[3]

Along these lines, there is an incredible requirement for expanding mindfulness about the significance of organ donation and the lawful arrangements identified with it. Understudies are youngsters who spread information, deprived for mindfulness as a rule open intrigue. So an organized instructing program was intended to be regulated among the University understudies to expand the information level by mediations.

Aims and Objectives:

1. To assess the mean pre and post-test of Knowledge and attitude score regarding organ donation.
2. To determine the effectiveness of structured teaching program on the mean knowledge and attitude scores.
3. To determine the association between knowledge and attitude regarding organ donation with selected socio-demographic variables.
4. To find out the relationship between knowledge and attitude regarding organ donation among students.

Material and Method

Study Design: This was a Pre-experimental one group pre-test and post-test study conducted on 100 students studying at Chitkara University, Punjab, India. Sampling technique used for the data collection is Purposive sampling Technique. Structured knowledge Questionnaire used for assessing the knowledge of students and 3 point Likert's scale was used for assessing the Attitude of the students. First Pre-test was conducted on students after that organized instructing programme was administered to the students immediately after this. Post-test had been conducted after 7 days and the collected data was analyzed with the help of SPSS.

Inclusion Criteria: Students who were studying at Chitkara University and want to be a part in study.

Exclusion Criteria: Those were not present during data collection.

Study Variables: The variables were Age, Religion, Gender, Family type, Education stream, Habitat, Information source.

Results and Discussion

The total 100 students were participated in structured teaching program regarding organ donation at Chitkara University Punjab. Table-1 depictsmaximum (90%) students were in the age of 18-21 years, followed by age up to -22 years (10%).Majority of the sample were found to be females (76%) whereas males were (24%). In religion wise distribution it was found that there were Hindu (57%), Muslim (6%) and Christian (4%).In relation to family it was found to be nuclear (65%) and joint (29%) and single parents (6%).Data presented in above table shows greater (73%) of students were form urban whereas (27%) rural area. Regarding previous board of school more than half (69%) of students were done schooling from private whereas (31%) were done from government. In case of experience of organ donation data presented in above table shows lesser have (7%) have experience of organ donation and greater have no personal/family experience of organ donation (93%). Table show bulk of students haven't attended any organ donation program previously (81%) and (19%) have attended. The sample were found to be getting information from internet/mass media (46%) and friends/family and health personnel (23%) and any other (8%).

Table 1: Frequency distribution of the level of knowledge of participants in pre-test & post-test. N=100

	Inadequate Knowledge (0-6)	Moderate Knowledge (7-12)	Adequate Knowledge (13-17)	Mean Score	SD
Pre Test	1(1%)	62(62%)	37(37%)	11.96	2.146
Post Test	0(0%)	34(34%)	66(66%)	12.91	1.531

Table 1 shows that there is difference between posttest mean (12.91) and pretest mean (11.96) knowledge regarding organ donation.

Table 2: Association between Knowledge levels with demographic variables N=100

Demographic Variables		Pre-Test Knowledge			Chi Test	P Value
Variables	**Options**	**Adequate Knowledge**	**Moderate Knowledge**	**Inadequate Knowledge**		
Gender	Male	12	12	0	2.492	0.288^{NS}
	Female	25	50	1		
Age (in years)	18 Years	6	15	0	5.985	0.649^{NS}
	19 Years	14	26	0		
	20 Years	13	15	1		
	21 Years	3	6	0		
	22 Years	1	0	0		
Religion	Hindu	19	38	0	3.968	0.681^{NS}
	Muslim	2	4	0		
	Christian	1	3	0		
	Sikh	15	17	1		
Family type	Joint Family	11	17	1	3.659	0.454^{NS}
	Nuclear Family	25	40	0		
	Single Parent	1	5	0		
Habitat	Urban	25	47	1	1.172	0.557^{NS}
	Rural	12	15	0		
Previous board of school	Government	10	21	0	0.961	0.618^{NS}
	Private	27	41	1		
Personal/family experience of organ donation	Yes	3	4	0	0.174	0.917^{NS}
	No	34	58	1		
Have you attended any organ donation program previously	Yes	6	12	1	4.455	0.108^{NS}
	No	31	50	0		
Information source of organ donation	Friends/family	7	16	0	14.799	0.022*

NS= non-significant at $p<0.05$ level

Table 2 describes that chi square test for association with the gender ($\chi2=2.492$), with age ($\chi2=5.985$), with religion ($\chi2=3.968$), with type of family ($\chi2=3.659$), with habitat ($\chi2=1.172$), with previous board of school, ($\chi2=0.961$) with personal/family experience of organ donation ($\chi2=0.174$), with have you attended any organ donation program previously related to knowledge ($\chi2=4.455$) and association with information of organ donation ($\chi2=14.799$).

The chi square value describes a significant association between level of knowledge score and information source ($p<0.05$). There is no significant association between level of knowledge score and other socio demographics profile.

Table 3: Association between attitude score with their socio demographic variables of the subjects N=100

Demographic Variables		**Pre-Test Attitude**			**Chi Test**	**P Value**
Variables	**Options**	**Poor Attitude**	**Satisfactory Attitude**	**Good Attitude**		
Gender	Male	19	5		3.119	0.07^{NS}
	Female	70	6			
Age (in years)	18 Years	19	2		1.606	0.808^{NS}
	19 Years	35	5			
	20 Years	25	4			
	21 Years	9	0			
	22 Years	1	0			
Religion	Hindu	52	5		3.883	0.274^{NS}
	Muslim	4	2			
	Christian	4	0			
	Sikh	29	4			
Family type	Joint Family	24	5		2.103	0.349^{NS}
	Nuclear Family	59	6			
	Single Parent	6	0			
Habitat	Urban	65	8		0.000	0.983^{NS}
	Rural	24	3			
Previous board of school	Government	25	6		3.203	0.073^{NS}
	Private	64	5			
Personal/family experience of organ donation	Yes	5	2		2.374	0.123^{NS}
	No	84	9			
Have you attended any organ donation program previously	Yes	18	1		0.789	0.375^{NS}
	No	71	10			
Information source of organ donation	Friends/family	23	0		5.405	0.144^{NS}

NS= non-significant at $p<0.05$ level

Table 3 delineates that chi square test for association with the gender ($\chi2$ =3.119), with age ($\chi2$=1.606) with religion ($\chi2$=3.883), with type of family ($\chi2$=2.103), with habitat ($\chi2$=0.000), with previous board of school, ($\chi2$=3.203) with personal/family experience of organ donation ($\chi2$=2.374), with have you attended any organ donation program previously related to knowledge ($\chi2$=0.789) and association with information source of organ donation ($\chi2$=5.405).

The chi square value shows there is no any significant association between attitude score and other socio demographic profile.

Table 4: Relationship between knowledge and attitude regarding organ donation among subjects N=100

Pair 1	vs	Pair 1	r value	P value
Pre Knowledge	vs	Pre Attitude	0.025	0.803
Post Knowledge	vs	Post Attitude	0.244*	0.015

*Correlation is significant at the 0.01 level (2-tailed).

Table 4 illustrates that there has been no relationship between pre knowledge and pre attitude but there is relationship between post knowledge and post attitude knowledge after structured teaching program.

Conclusion

Based on the present study knowledge level of students increases after structured teaching and also change in attitude level. There was significant association between level score of knowledge with information source whereas no statistically significant association was found with demographic variables.

Variation in Sleep Pattern Due to Lockdown among Collegiate Students

Manisha Bhandari[1], Rabab Kaur[2]

[1]Student, Galgotias University, [2]Assistant Professor, Galgotias University, Plot No. 2, Yamuna Expy, Opposite, Buddha International Circuit, Sector 17A, Greater Noida, Uttar Pradesh 203201

Abstract

Background: Due to the vast spread of corona virus, lockdown was announced in many countries, and hence many people are facing psychological, physical, economic and social changes. Students at the college experience a variety of sleep problems which can have a direct effect on academic success, health and mood. Sleep disruption and excessive daytime sleep are common problems for students.

Subject and Method: 141 college students between the age of 17 to 24 were taken from various colleges. The structured Pittsburgh Sleep Quality Index was used and was circulated amongst students through Google forms and the sleep log, and demographic sheet was used to test sleep length, daytime sleepiness and related sleep issues.

Study Design: A cross sectional study.

Results: The result, on the basis of the sleep pattern of college students, was classified into 5 categories: (healthy sleep pattern, mild, moderate, severe and worst). 53.90% out of 141 respondents o had healthy sleep pattern range (0-5), 39.71% had mild sleep pattern range (6-10), 4.96% out of 141 respondents had moderate sleep pattern range (11-15), and 1.41% out of 141 respondents had severe sleep pattern range (16-20).

Conclusion: In our study we found that during the lockdown majority of college students had a healthy sleep pattern and least of the college students had a severe sleep pattern range.

Keywords: *Pittsburgh Sleep Quality Index, Coronavirus, Lockdown, sleep pattern, college students.*

Introduction

Sleep is a physiological process that can alternate with internal and external stimulation between conscious stage and unconscious stage[1]. Sleep absorbs about one third of our lives and thus it plays a crucial role which is key to emotional, physical development and stability. A good sleep is needed for better growth and stability, if there is lack of sleep than it may decrease physical and mental capacities along with mental problem such as anxiety and depression, therefore sleep loss has tremendous impact on both society as well as individuals[2]. Now days the second most common symptom of mental distress is commonly known as sleep disturbance, according to many surveys now days one third of college students reports difficultly in sleeping[3]. Now days insufficient sleep and irregular sleep wake schedule among the college student are becoming major health problem, which is directly related to decrease the quality of life, due to the hectic schedules college student suffer from sleep disturbance, fatigue and mood change[4]. Many research show that there is high chance of sleep disturbance in college student than the general population[5].

Sleep disturbance for college students is directly associated with cognition, academic performance, emotional, intelligence, psychological and physical health. Still no research is available on the impact of sleep quality on college student's health and well-being. The main factor for sleep disturbance to the college students are all nightery parties, late-night studying and social obligation, work and alcohol/or drug abuse[8] . It's hard to fall asleep earlier in the evening for the college

students because they cannot wake up early. In addition, the college students sleep pattern is characterized by inadequate length of sleep, delayed onset of sleep and frequency of napping during the day that directly affect the study[9].

The world health organization (WHO) confirmed in January 2020 the outbreak of a new corona disease, Covid-19 which had already reported that there is a potential high risk of covid-19 spreading to the entire world[10]. As a consequence of the spread of covid-19 disease, almost all countries form formulated the guidelines which include isolating, lockdown quarantining and social distancing at these times. Lockdown is the concept used for separation, or restriction of movement of the community during an epidemic of infectious disease. Because of a dramatic rise in covid19 incidents the government imposed an immediate lockdown to prevent the disease from spreading across the population[11]. Nowadays, the current situation is facing negative effect on many factors which influence sleep quality and almost all people are experiencing major changes in their daily life[12]. In lockdown college students increased the use of digital media to alter sleep habits at bedtime. The increased sleep pattern leads to higher levels of depression, anxiety, and stress in many people [13]. Sleep issue can be significant concern for all during the lockdown, but some individuals are at higher risk of experiencing sleep problems than others. Women experience poor sleep and insomnia more often than men. In addition, students can depend on their phone with the likelihood of mobile phones, which directly affects the sleep pattern. According to the national sleep foundation in the U.S. 2011 task force, 50 percent of young adults use their cell phones and the internet before they sleep. The improper use of computers and mobile devices in the bedroom thus delays bedtime and the raise time [14] .

Methodology

This chapter discusses the process used for the analysis which provides explanation of the topics used in data collection and analysis and procedures. The research Sample consisted of 141 College Students based on the structured questionnaire respondents.

The subject of this study was 141 college students. The primary data was collected from college students by using stratified random sampling method. Universe of this present study was the college students in lockdown, India . Besides that, all of them were between 17 to 24 years of age. The data has been collected through college students by structured questionnaires using online Google form.

Inclusion Criteria:

1. Gender- male and female
2. College students
3. Subject should be between 17 to 24 years
4. Able to understand Hindi and English language
5. Individuals who were cooperative
6. Young healthy individuals

Exclusion Criteria:

1. Students with neurological issued
2. Non-cooperative subjects

Result

In this survey study 141 subjects participated and answered all the questions of sleep quality questionnaire and also provided detailed demographic information including name, age, gender, contact number, address, and contact details for email.

The Pittsburgh sleep quality index (PSQI) was used. Table 1 shows subjective sleep quality and according to it 32.6% out of 141 respondents, sleep quality rate is very good, 48.9% out of 141 respondents, sleep quality rate is fairly good, 13.4% out of 141 respondents, sleep quality rate is fairly bad and 5 % out of 141 respondents, sleep quality rate is very bad. According to table 2 30.4% out of 141 respondents took less than 15 minutes to sleep at night, 42.5% out of 141 respondents took 16 -30 minutes to sleep at night, 14.1% out of 141 respondents took 31-60 minutes to sleep at night and 12.7% out of 141 respondents took more than 60 minutes to sleep at night. Table 2.1 shows that 56.7% out of 141 respondents had trouble sleeping in the past month because they could not sleep within 30 minutes, 17.02% out of 141 respondents had trouble sleeping less than once a week because they could not get sleep within 30 minutes, 14.8% out of 141 respondents had trouble sleeping once or twice a week because they could not get sleep within 30 minutes and 11.3% out of 141 respondents had trouble sleeping three or more times a week because they could not sleep within 30 minutes.

In table 2 and figure 2 we calculated the component in which we analyzed the responses of question 2 and 5a.

For component 3, 3 43.9% out of 141 respondents got 7 hours or more hours of actual sleep at night, 48.3% out of 141 respondents got 6 to 7 hours of actual sleep at night. 5.6% out of 141 respondents got 5 to 6 hours of actual sleep at night and 2.1 % out of 141 respondents received 5 hours of real night-time sleep. For component 4, sleep effectiveness of sleep is determined by using formula (hours slept ÷ hours in bed)×100. For component 5, 14.1% out of 141 respondents had sleep disturbance during the past month, 69.9% out of 141 respondents had sleep disturbance less than once a week, 16.3% out of 141 respondents had sleep disturbance once or twice a week and 0% out of 141 respondents had sleep disruption three times or more.

The component 6 shows that 83.6% out of 141 respondents have taken sleep medicine during past month, 9.21% out of 141 took sleep medicine less than once a week, 6.38% out of 141 took sleep medicine once or twice a week and 0.70% out of 141 took sleep medicine three or more times a week. For component 7, 64.5% out of 141 respondents had trouble staying awake in the last month, 19.1% out of 141 respondents had trouble staying awake less than once a week, 12.7% out of 141 respondents had trouble staying awake less than once or twice a week and 3.5% out of 141 respondents had difficulty staying awake three or more days a week. Table 7.1 reveals that 51.0% out of 141 respondents had no issue at all in maintaining enthusiasm for doing things, 29.7% out of 141 respondents had only a very slight problem, 16.3% out of 141 respondents had somewhat of a problem and 2.8% out of 141 respondents had a very major problem.

Table 1: Quality of Subjective sleep and Latency sleep

Frequency (N)	Percentage	Sleep Quality Response	Component Score
46	32.6%	Very good	0
69	48.9%	Fairly good	1
19	13.4 %	Fairly bad	2
7	5%	Very bad	3
Frequency (N)	**Percentage %**	**Time to fall asleep**	**Component score**
43	30.4 %	≤ 15 minutes	0
60	42.5 %	16-30 minutes	1
20	14.1 %	31-60 minutes	2
18	12.7 %	>60 minutes	3

According to Table 1: 32.6% out of 141 respondents, sleep quality rate is very good, 48.9% out of 141 respondents sleep quality rate is fairly good, 13.4% out of 141 respondents sleep quality rate is fairly bad and 5 % out of 141 respondents sleep quality response, the percentage is very low.

30.4% out of 141 respondents take time to sleep at night in ≤ 15 minutes, 42.5% out of 141 respondents take time to sleep at night in 16 -30 minutes, 14.1% out of 141 respondents take time to sleep at night in 31-60 minutes, 12.7% out of 141 respondents take time to sleep at night in > 60 minutes.

Table 2: Duration of sleep

How many hours you have got to sleep at night during the last month?

Frequency	Percentage %	Sleep duration	Component score 3
62	43.9%	≥ 7 hours	0
68	48.3%	6-7 hours	1
8	5.6%	5-6 hours	2
3	2.1%	5 hours	3

According to Table 2: Among the 141 responses, 43.9% receive 7 hours among actual night-time sleep, 48.3% receive 6 to 7 hours of actual night-time sleep. Among the 141 responses, 5.6% receive 5 to 6 hours among real sleep at night and 2.1% receive 5 hours of actual night-time sleep.

Table 3: Sleep efficiency

Frequency (N)	Sleep efficiency	Component 4 score
101	>85%	0
15	75-84%	1
16	65-74%	2
9	<65%	3

According to **Table 3** sleep efficiency is calculated by using formula (hours slept ÷ hours in bed)×100

Table 4: Sleep disorder and use of medication for sleep

Frequency	Percentage	Sleep disturbance	Component 5 score
20	14.1%	Not during pass month	0
98	69.9%	Less than once in a week	1
23	16.3%	Twice or once a week	2
0	0	Three or more times per week	3
Frequency (N)	**Percentage %**	**Use of medication for sleep**	**Component Score**
118	83.6%	Not in the past month	0
13	9.21	Less than one week	1
9	6.38	Once or two times a week	2
1	0.7%	Three or more times per week	3

According to Table 4: 14.1% have sleep disturbance not during pass month, 69.9% out of have sleep disturbance less than once a week, 16.3% out of have sleep disturbance once or twice a week and 0% out have sleep disturbance have occurred three or more times per a week.

83.6% have taken sleep medicine not during past month, 9.21% have taken sleep medicine less than once a week, 6.38% have taken sleep medicine once or twice a week and 0.70% have taken sleep medicine three or more times per week.

Table 5: Dysfunction on the day

Frequency (N)	Percentage %	Over the past few month, how often have you had trouble staying awake while driving, eating, or socializing?	Score
91	64.5%	Not during the last month	0
27	19.1%	Less than one week	1
18	12.7%	Once or two times a week	2
5	3.5%	Three or more times per week	3

According to Table 5: 64.5% have trouble staying awake not during the past month, 19.1% have trouble staying awake less than once a week, 12.7% have trouble staying awake once or two times a week and 3.5% have trouble staying up three or more times per week.

Global PSQI Score: A total of seven components

Table 6

Frequency (N)	Percentage %	Range (0-21)	Sleep Quality
76	53.90%	0-5	Healthy
56	39.71%	6-10	Mild
7	4.96%	11-15	Moderate
2	1.41%	16-20	Severe
0	0%	21-25	Worst

According to the global PSQI score: 53.90% have healthy sleep quality,39.71% have mild sleep quality,4.96% have moderate sleep quality and 1.41% have severe sleep quality.

Result

Global PSQI Score: Sum of seven components: According to the global PSQI score 53.90% out of 141 respondents of college student have healthy sleep pattern, 39.71% have mild sleep pattern,4.96% have moderate sleep pattern and 1.41% have severe sleep pattern.

Discussion

We investigated variation of the college students sleep pattern during lockdown in cross- sectional study. As expected, during lockdown college students sleep pattern may be changed. The information of the results must consider the limitations of the study mainly depend on self- reports regarding sleep schedule. The COVID-19 pandemic has created damaged millions of people to live under strict blackout conditions and people who go to bed and wake up late, spend more time in bed and record a poorer standard of sleep as well. Decreased sleep quality was stronger with high levels of depression, anxiety, and stress. Loss of sleep among college students poses a serious risk to academic performance, both physical and emotional health. For the study, a total of 141 college students were chosen, they were evaluated for the parameters of inclusion and exclusion criteria. College student sleep pattern is tested on the basis of the result of PSQI they were put under the five groups namely 1) Good Sleep quality, 2) Mild Sleep quality,3) moderate Sleep quality, 4) Extreme Sleep quality, and 5) Worst Sleep quality.

In our study one questionnaire is used to determine the sleep pattern of college students during lockdown. The questionnaire instruction analyzed the results. There are seven component scores in the scoring PSQI, each score 0 (no difficulty) to 3 (severe difficulty).Scores of the components are summed up to generate a global score (0 to 21) higher score mean poorer quality of sleep. Good and satisfied sleep is not only central to sound body health, but is also of primary importance to cognitive and social activities. Learning plays a significant part in learning and memory process for the students.

In our analysis we identified the characteristics of socio-demographic and lifestyle, nighttime behaviors and sleep habits and their results. Besides low sleep quality students also showed poor quality of sleep. Table 1 reveals that 32.6% out of 141 response of college have very good sleep pattern and 5% out of 141 responses have very disturbed sleep pattern. Poor sleep quality has been associated with negative moods reported to be significantly higher by themselves. Table 2 shows 42.5% out of 141 response of college student take 16 to 30-minute times to sleep at nights. 12.7% out of 141 response take more than 60 minutes to sleep at night so we should stick to the same sleep schedule and wake up time even on the weekends, so that it can help us sleep at right time. Comparing the previous study, we found that 43.9% had more than 7 hours of real night sleep and 16.3% had once or twice a week disrupted sleep. Sleep medicine is taken once or twice a week by 6.38% students.

According to this research we found global PSQI score is used to sum the seven components. In the current study, data shows that during lockdown majority of the college student had healthy sleep pattern (53.90%) range of the PSQI (0 -5), 39.71 % had mild sleep pattern range of the PSQI (6-10), 4.96% had moderate sleep pattern range of the PSQI (11-15) and 1.41 % had severe sleep pattern range of the PSQI (16-20).

Limitations of the study:

- One of the limitations of this study is small sample size, study was of short duration, the interval between the age group is less and study is done on young healthy individuals only.
- Another drawback was that this analysis consisted of a one- time study, so it is difficult to determine the connection between sleep disturbance and poor sleep quality.

Recommendations:

- This analysis can be carried out on a larger sample size.
- The period of research can be longer.
- There may be variations in the age group used for study.

Conclusion

We assume there is need for more research into sleep cycle and their effect on the working. There should be a study of students with good sleep habits. Sleep requirements differ according to individual needs. Some need more than 7 hours of effective sleep, other may need as little as 5 hours of sleep. Further research can identify factors in lifestyle which promote good quality of sleep.

In the current study we found that during lockdown period most students had a healthy sleep pattern. Sleep disorder can have a huge effect on people lives. These findings support that there is no variation of sleep pattern during lockdown. Healthy sleep pattern decreases the anxiety, tension, depression and stress .

Patient's Knowledge and Satisfaction with health Care of a Tertiary Care Hospital Situated in Rural area of Northern India (Haryana)

Manisha Rani[1], Jyoti Phougat[2], Manpreet Kaur[3]

[1]Former Assistant Professor, Pediatric Nursing Department, Maharishi Markandeshwar Institute of Nursing, Maharishi Markandeshwar (Deemed to be University), Mullana, Haryana, India (At Present: Nursing Officer Deputed as Nursing Tutor, Pediatric Nursing Department, Nursing College, All India Institute of Medical Sciences (AIIMS) Bhopal (M.P.), India), [2]Assistant Professor, Pediatric Nursing Department, M.M. Institute of Nursing, MMDU, Mullana, Haryana, India, [3]Assistant Professor, OBG Nursing Department, M.M. Institute of Nursing, MMDU, Mullana, Haryana, India

Abstract

Background: Nowadays health care quality is a universal concern. The most appropriate method to measure a client's experiences about available hospital services is a patient satisfaction survey. Present study aimed to assess patient's knowledge and satisfaction regarding health care.

Method: 330 patients were selected by purposive sampling technique attending various outdoor and indoor departments of the selected hospital. Self-structured checklist and three-point rating scale each containing a total 50 sets of items used to assess knowledge and satisfaction. The reliability coefficient for the knowledge tool was 0.87 by KR 20 and satisfaction was found 0.85 by Cronbach's Alpha.

Result: Study results showed that more than half (52.4%) and (60.6%) patients had very good level of knowledge and 76.4% & 67.5% of patients were satisfied with overall health care. Item wise distribution of satisfaction among patients reveals that "physician gave follow up instructions to the patient properly (78.2%)", "OPD card facility (78.2%)," and "hospital food facility for patients (75.2%)" was found ranked 1st with the highest satisfaction, whereas "Free of cost availability of drugs", "long queues during OPD card registration process" was found ranked lowest. A significant low positive correlation found between mean knowledge and satisfaction scores regarding health care services as evident by computed 'r' value (0.38).

Conclusion: Using these necessary responses from the patients, various shortcomings can be pointed out and notify to hospital administration for improvement of the health care.

Keywords: *Knowledge, satisfaction, Health care, Tertiary care hospital.*

Introduction

Satisfaction, like quality, is multifaceted construct[20]. Satisfaction of clients premised on multifarious strands in a health care organization. Client's expectancy and his perception with health care and services are directly congruent[21]. Among all the method, assessment of client's satisfaction is the vital for the evaluation of Excellencies in a health care organization. It is important to assess the satisfaction rate of the services which will evaluate whether the services are useful or not[22]. In the recent epoch, many dimensions together with behaviour of employees,patient staff interaction along with administration issues of the hospital and diagnostic services are crucial aspects of patient satisfaction[23]. A happy patient has higher adherence to treatment

protocols and goes for routine follow up for his ill health[24]. Pragmatic evidences confirm that majority of health care organizations in India are measly involved in the assessment of satisfaction rate. The long queues in the OPD areas, little and unkempt waiting areas, poor condition of bathrooms, unsympathetic approach of health care workers bear articulate testimony to the current fact. Entire considerations make the assessment of patient's satisfaction with health system even highly necessary[25]. In recent years, patients have become a lot conscious to their rights and cognizant regarding their health. They demand best health care in each facet. Patient's feels unsatisfied when services received by them are not according to their expectations[26]. Developed countries have many research studies and literatures on satisfaction of patients with health care services but this number is very less in case of developing countries including India. Satisfaction assessment will offer valuable and exclusive insights into routine health care in hospital. It is broadly accepted as an autonomous dimension of quality of care as analysis of patient satisfaction includes "internal" (inward-looking) aspects of hospitalization, which frequently stay unrecorded, like communication, warmth or interaction7. Satisfaction of patient regarding health care facility situated in a rural area is of vital significance for providing quality services to patients, so keeping this point in consideration; the present research study was conducted to assess patient's knowledge and satisfaction with heath care of a tertiary care hospital situated in a rural area of Northern India (Haryana).

Material and Method

Study Design and Study Area: This was a cross-sectional study based on a descriptive survey design conducted in a tertiary care center situated in the rural area of northern India. The hospital is a center for undergraduate and postgraduate medical teaching and has an operational strength of 940 beds. Patients are mainly seen in the Outpatient Department causality unit and special clinics. It receives patients from within Haryana, and the neighboring states of India (Uttar Pradesh, Himachal, Punjab, and Chandigarh). The majority of patients are indigenous Hindu, although the Muslim and Sikh ethnic groups also constitute a substantial proportion of the clientele. Clients with various occupational backgrounds like farmers, private, and govt. service holders, businessmen, etc get the benefit of services present over here.

Written informed consent was obtained from all the participants before starting the study. Data for the study was collected from clients in OPD (Out Patient Department) andIPDs i.e.admitted in medicine, surgery, orthopedics, neurosurgery, and gynecology ward of MMIMS & R hospital Mullana, Ambala, Haryana.

SampleSize and Sampling Technique: Using a Non-probability Purposive sampling technique a sample size of 330 was taken to detect the knowledge and satisfaction among the study participants regarding health care. However, patients referred or advised for or admitted to the Intensive care unit/cardiac care unit/ emergency with conditions related to psychiatry or maternity, and those with critical health issues were excluded.

Tools and Technique of Data Collection: A structured knowledge checklist and rating scale were prepared to assess the knowledge and satisfaction regarding health careamong outdoor and indoor patients. Both toolconsisted of 50 items each divided into 2 parts according to areas of hospital services-physician services and basic services i.e OPD services, Diagnostic services, Admission & discharge services, Laundry and food services, Drug availability and administration.

In knowledge tool each item consist maximum 1 score and minimum score 0. The score obtained by the indoor patient were arbitrarily categorized into four levels- Very good (>75%), Good (61-75%), Average (50-60%), Poor (<50%).

Rating scale for level of satisfaction had a score of 3 point i.e., satisfied score as 3, partially satisfied as 2, dissatisfied as 1. The score obtained by the indoor patient were arbitrarily categorized into three levels -: Satisfied (>75%), partially satisfied (50-75%), Dissatisfied (<50%).

Reliability of the structured knowledge checklist and Rating scale was computed using Kudar Richardson 20 (KR-20) and Cronbach alpha method which was found 0.83 and 0.80 respectively. The tool was found valid, reliable, and feasible for the purpose of the study. Both tools were validated by 8 experts in the various nursing fields. An interview technique was used to collect the data of the present study.

Statistical analysis Collected data were entered into Microsoft Excel software and data cleansing was performed. Data were analyzed using SPSS

IBM Statistics version 20. Descriptive statistics were generated using mean, standard deviation (SD), frequency, and percentages. Analytical statistics like correlation coefficient and Chi-square test was used to see correlation and association. The value of $P < 0.05$ was considered statistically significant.

Results

Description of sample characteristics: Frequency and percentage distribution was computed to describe the sample characteristics of the sample. The baseline sample characteristics of the participants showed that 47.9% patients were females and 52.1% were males and as regard to the religion 61.4%,26.7% patients was Hindu and Muslim respectively, 11.6% was Sikh, and 0.3% belong to Christian religion.

Less than half, (35.2%) patients were having education upto primary school and, (3.6%) were having senior secondary education. Family income of 46.1% patients was Rs <5000 and only 5.5% were having Rs >20,001 & above per month. More than half patients (51.5%) were from joint family, and other 48.2% were from nuclear family. As regard to previous hospitalization 52.1%were admitted previously in hospital and 47.9% were not admitted previously and as regard to the type of hospital 32.4% admitted in private hospitals previously and 19.7% admitted in government hospitals. More than half(68.8%) have less than 2 visits in hospital previously and, 3.9% has more than 4 visits. Nearly half number of patients, (42.4%) had 1-4 days length of stay and, 9.7% had more than 12 days length of stay in the hospital.

Area wise frequency and percentage of levels of knowledge among indoor patients regarding health care services: More than half (52.4%) & (60.6%) patients were having very good level of knowledge and 7.2% & 6% were with below average knowledge regarding availability of physician services and basic services i.e OPD services, Diagnostic services, Admission & discharge services, Laundry and food services, Drug availability and administration respectively.

Frequency and percentage of level of satisfaction regarding Physician services, and basic services: - Findings shows that more than half (76.4%) (67.5%) patients were satisfied with physician services and basic services (OPD services, Diagnostic services, Admission & discharge services, Laundry and food services, Drug availability and administration) of hospital respectively. (as shown in figure 1).

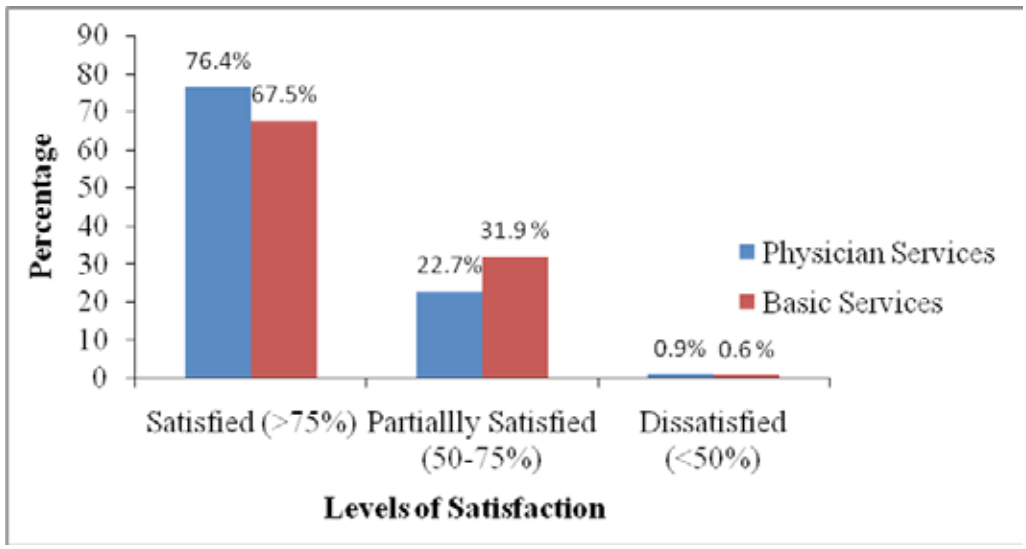

Figure 1: Bar Graph Showing the Percentage of Level of Satisfaction among Indoor Patients Regarding Physician Services and Basic Services

Item wise distribution of level of satisfaction among patients regarding physician services: Results reveal the frequency, percentage and rank order of level of satisfaction regarding various physician services. Among these, "gave follow up instructions to the patient properly" was found 78.2% ranked 1st, "favoured patients over other." was found 50.6% ranked lowest as shown in table no. 1

Table No. 1: Item Wise Distribution of Level of Satisfaction among Patients Regarding Physician Services N=330

Item wise distribution of satisfaction among patients regarding Laundry & food services and Drug availability and administration: Frequency, percentage and rank order of satisfaction regarding Laundry and food services reveals that satisfaction for "Hospital food facility for patients (75.2%), Availability of clean bed sheets, Pillow and Blanket ranked (60%) ranked first and 2nd respectively whereas "Availability of laundry for washing personal clothing (33.4%)" ranked lowest as hospital is not having laundry facility for washing personal clothing.

For Drug availability and administration, item wise distribution of satisfaction revealed that Patients were highly satisfied with "Administration of drug on right patient at right time (69.1%)" whereas "Free of cost availability of drugs (16.7%)" found at lowest rank.

A significant low positive correlation was found between mean knowledge and satisfaction scores of indoor patients regarding nursing services and physical infrastructure as evident by computed 'r' value of (0.38).

Chi square value showing the association of knowledge score regarding availability of health care services of hospital with selected sample characteristics: Results of Chi square association indicates that type of family (10.47) and present medical conditions (5.99) was found statically significant at 0.05 level which indicate that rate of scoring of knowledge was dependent on type of family and present medical condition, as most of the patient who belonged to joint family have more level of knowledge as they received information from family members and their relatives and the patient with acute illness were more oriented and able to receive information regarding available health care services.

The finding also revealed age, gender, religion, marital status, education, occupation, family income per month, number of visits, previous hospitalization was found statistically non significant at 0.05 level.

Chi square value showing the association of satisfaction score regarding availability of health care services with selected sample characteristics: A chi square association with level of satisfaction indicates that Religion (20.96), occupation (9.79), and type of hospital (6.48) were found statistically significant at 0.05 levels which indicate that satisfaction was dependent on religion, occupation and type of hospital previously admitted. The findings also revealed that age, gender, type of family, marital status, education, family income per month, number of visits, previous hospitalization was found statistically non significant at 0.05 level.

Discussion

Results of our study shows that 76.4%patients have overall satisfaction regarding physician services. Among these, "gave follow up instructions to the patient properly" was found 78.2% ranked 1st, these results were found to be consistent with the study conducted by Kumari R to determine the areas and causes of low satisfaction among the patients and suggest method for improvement. Result shows that the overall satisfaction regarding the doctor-patient communication was more than 60% at health care facilities but for examination and consultation by physician was less than 60%[27]

Findings of our study revealed that satisfaction for "listening the problem told by patient" was found 64.8%, more than half patients (64.5%) were satisfied with waiting area with sitting arrangements in OPD area where as very less patients were satisfied with cleanliness of toilets(33.5%), These results were found to be consistent with the study conducted byAntenehAsefa(2014)reveals that according to71% patients, health care providers were very polite with patients, 64%said that there was convenient environment to ask question/s, 66% were satisfied with comfort of waiting area[28]. Study result also coincide with another study conducted by Kumari R, according to this less than half patients were satisfied with availability (44.7%) andcleanliness of the toilets (31.3%), for availability of seats in waiting area satisfaction rate was high(81.4%)8

Findings of our study further revealed that more than half (79.1%) patients were satisfied with Sample collection in Laboratory, according to 57.6% patients, admission process was satisfactory. Hospital food facility was satisfactory for 75.2% patients. 69.1% found "Administration of drug on right patient at right time" process acceptable. These results were found to be consistent with the study conducted by Bishwalata R (2020), findings reveals that (51.7%) found the waiting time and admission procedures acceptable, around 55.7% patients said that they always received medication in a timely manner. For 37.2% of the patients, all scheduled investigations were not done in the hospital. (24.9%)expressed dissatisfaction with the quality of the foodserved.[29]

Stress in Working Women Due to Lockdown: A Cross Sectional Survey

Manjeet Singh[1], Rabab Kaur[2]

[1]Student, Galgotias University, [2]Assistant Professor, Galgotias University, Plot No. 2, Yamuna Expy, Opposite, Buddha International Circuit, Sector 17A, Greater Noida, Uttar Pradesh 203201

Abstract

Background and Purpose: Due to the vast spread of coronavirus, the lockdown has been announced in many countries, and hence many people are facing psychological, physical, economic and social issues. It has targeted all the population but this study focuses on the increased amount of perceived stress on women who are undergoing work from home pattern of occupation.

Methodology: Sample comprised of 110 working women. The structured questionnaire, Perceived Stress Questionnaire, was circulated through online google forms. Along with stress, demographic sheet was used to study stress in working women due to lock down.

Result: The outcome, view of the respondents based on feeling of anxiety of working ladies was classified into 3 categories (Mild, Moderate, Severe) and range. 7 persons of respondents are in 0.01 - 0.40 range i.e. 6.36%, 101 persons of respondents are in 0.40 – 0.70 range i.e. 91.81%, 2 persons of respondents are in 0.70 – 1.00 range i.e. 1.81%.

Conclusion: In this investigation we found that a large population of the females are under moderate pressure and are overstressed while carrying out work from home.

Introduction

'Stress' word has been subordinate from material science and mechanics where it is particularly portrayed as physical weight applied upon, and between different bits of body, when bending occurs as conclusive item it is called strain.[1] Stress is a disagreeable and widespread experience which is influences every one of us in various manners and at various occasions in the present supercharged working environment. Ladies are additionally almost certain than men to be unfavorably influenced by mental clutters. Employment stress is characterized as the hurtful enthusiastic and physical reaction which happens because of prerequisites of the activity don't coordinate the abilities, assets, or requirements of the laborer. It is extensive proof that the worry because of double job of ladies at a work spot and home and that innate in contrarily impacts their personal satisfaction.[2]

After freedom, ladies in India have made some amazing progress. From only a master homemaker/ housewife, she not just has gained aptitudes and capacities to being an ideal housewife however being at same level with their companion or life accomplice. Presently, ladies need to catch up their fantasy vocation and this is the new proliferation of working ladies.[3,1] The Industrial Revolution to some degree was fuelled by the financial need of numerous ladies, single and wedded, they are found pursued work outside their home. Generally, ladies secured positions in local assistance, piece workshops, and material manufacturing plants. They are likewise worked in the coal mineshafts. For a few, the Industrial Revolution gave free wages, portability and a superior way of life.[4] In India, post globalization, there is unmistakable changes in perspectives of ladies and the general public's viewpoint towards them. In the course of recent decades that has been a continuous acknowledgment of work jobs in ladies. Over the globe, ladies are venturing out of the security of their homes to confront difficulties of more up to date sorts.[5] Along

these lines doing obligations and duties both at home and working environment overstrains a wedded working lady, in this manner prompting different mental issues like job struggle, work strain, mental weariness, stress, uneasiness, disappointment, sadness, outrage, fears, and other social and passionate pain. These issues can intelligently influence the psychological prosperity of working ladies and all the more so in wedded working ladies.[6]

Lockdown, a term routinely utilized as proxy for "mass isolate", is normally founded on "stay-at-home" or "safe house set up" laws given by an open (either national or provincial) government or authority, for forcing social removing and subsequently constraining or totally canceling the development of the populace inside and outside a particular zone. It is consequently generally utilized with respect to balancing a progressing episode, ordering occupants to remain inside their homes, aside from doing basic exercises (wellbeing visits, keeping an eye on a helpless individual, buying prescriptions, food and drinks) or giving basic work (for example medicinal services and social consideration areas, police and military, firefighting, water and power flexibly, basic assembling). Other insignificant exercises are thus halted or done from home.[7] In a male driven culture like India it is as yet acknowledged that a man is the fundamental supplier of his family. But Indian women have started working outside their home yet simultaneously they have far to go both socially, socially and fiscally, to get productive attitudinal changes in the mindset of people.[8] Anxiety, stress and oppressive indications are normal in a combination of mental states (Kvaal et al. 2005). In connection with men, women are will undoubtedly make strain issue over their future (Bruce et al. 2012; Mclean and Hofmann 2012). According to the US National comorbidity review, the lifetime inescapability rates for any apprehension issue were 19.2% for men and 30.5% for women (Mclean and Hofmann 2012).[9] The conventional arrangement of male prevalence or male overwhelmed cultural set up makes various difficulties ladies at their work place. It is an inborn conviction that ladies' work capacity and productivity is lesser than men. The youthful female age has changed the intrinsic male centric structure on ladies in the general public that was getting common until the finish of the twentieth century in India.[10] We conjectured that more significant levels of pressure and more manifestations of wretchedness or tension would be related with expanded normal cortisol levels and a smoothed diurnal cortisol design.[11] At the point when everything is said in done, women are practically sure than men to experience physical appearances of worry, for instance, shortcoming, instability, cerebral agonies, and wretchedness. Women are furthermore more likely than men to adjust to work stress with bothersome practices, for instance, helpless dietary examples.[12] A significant issue in exploring the pressure issue connection is the contiguity between upsetting occasions and turmoil.[13] The lockdown – in full power as we compose – limits 1.3 billion individuals from leaving their homes. Transport administrations are suspended, instructive organizations are shut, and manufacturing plants are closed down. This is in accordance with the measures forced in most European nations and in the United States, however the sheer size of the measure – as on account of most approaches in India – is threatening.[14]

Methodology

This chapter discussed the process used for the analysis which provides explanation of the topics used in data collection and analysis. A Cross- Sectional Survey was carried out. Sample size of 110 working females were taken. The data has been collected through structured questionnaire using online google form by working women. Stratified random sampling method.

Inclusion Criteria:

1. Gender - Females
2. Age – 25 to 60 years
3. Able to understand English

Exclusion Criteria:

1. Pregnant women
2. People who have difficulty in understanding English or other communication issues
3. The population having any neurological issues

Data Analysis: The essential information was gathered by conveying a poll among the working ladies by means of google structure, the individuals who are adhered at home because of lockdown in India. The investigation was led between April-May 2020. Information were gathered by various angles identified with the work environment, factors adding to pressure, indications and outcomes of stress and diverse adapting methodologies received by working ladies to manage pressure.[1]

Understanding of Data: The understanding of the information was investigated through rate as information has been accumulated from 110 respondents. It was done in the accompanying way:

Table 1 Age assumes a significant job in worry among working ladies. The age of the respondents is arranged into three classifications. Table 4.1 shows that out of 110 respondents, 81% are in the age gathering of 30-40, 14.4% are in the age gathering of 40-50, 4.5% are in the age gathering of 50-60.

Table 1: Age group of females

Age	No. of Respondents	Percentage (in %)
25-40	89	81
40-50	16	14.4
50-60	5	4.5
Total	**110**	**99.9**

Table 2: Mental and physiological side effects of worry among working ladies in Lockdown

Total	Stress Symptoms	Almost	Sometimes	Often	Usually
110	You feel rested	15	75	17	3
110	You feel you are doing things you really like	24	38	45	3
110	You feel calm	32	48	26	4
110	You are full of energy	17	48	39	6
110	You feel safe and protected	19	46	31	14
110	You enjoy yourself	18	42	39	11
110	You are lighthearted	11	55	35	9
110	You have enough time for yourself	13	52	36	9

Table 2 shows the consequence of information gathered from 110 respondents based on mental and physiological manifestations of worry among working ladies. 13.63% respondents said that they feel rested because of stress, while 68.18% said that occasionally and 15.45% feel regularly and 2.72% normally. 3.63% respondents said that they typically feel issue of quiet.

Table 3: Qualification of women

Qualification	Number of women	Percentage (in %)
Teacher	45	40.9
Engineer	18	16.3
Private limited company	30	27.2
Other service(s)	17	15.4
Total	110	100

Table 3 shows the view of the respondents based on their capability. It is characterized into 4 classes. 40.9% of respondents are instructors, 16.3% of respondents are engineer, 27.2% of respondents are private constrained organization and rest 15.4% have other expert help.

Table 4: Stress Level of Working Women

Description	Range	Person	Percentage (in %)
Mild	0.01-0.40	7	6.36
Moderate	0.40-0.70	101	91.81
Severe	0.70-1.00	0	1.81
Total		**110**	**99.9**

Table 4 shows the outcome, view of the respondents based on anxiety of working ladies. It is arranged into 3 classes (Mild, Moderate, Severe) and go. 7 man of respondents are in 0.01 - 0.40 territory and 6.36%, 101 man of respondents are in 0.40 – 0.70 territory and 91.81%, 2 man of respondents are in 0.70 – 1.00 territory and 1.81%.

Discussion

In the current investigation, while the privately settled working women uncovered more satisfaction than working women, the past scored lower on certainty (both saw and socially observed), which shows that working from home could be both liberating and restricting. Though privately arranged working ensured versatility,

it impacted the women's needs to develop themselves full-time into their callings, harden their financial self-rule and not wait behind their companions, which were as strong as that of their working accomplices (Rani, 1976). It was found that family stress, family difficulty, and work-family work over-trouble can transform into a grave issue for the working woman and can have a negative impact upon her general prosperity, work execution, and occupation satisfaction.[4] An investigation on data innovation area working ladies which utilized authoritative job pressure scale detailed higher feeling of anxiety as the age expanded, a finding rather than our examination. To restrict the apprehension issue, there should be a fine agreement between the quality and whole of information one needs to extend. Information from unconfirmed sources and web-based life stages make sure to cause furious and make you annoyed. Obliging on the web life use can in like manner be a guide to our mind and enthusiastic health.[19] This examination shows that high paces of depression, anxiety, insomnia and perceived pressure, with young ladies having higher chances of embracing a psychological well-being result. These results were related with various COVID-19-related hazard factors, including being under isolate, having a friend or family member perished by COVID-19, the working movement stopped because of lockdown gauges, or encountering other upsetting occasions (for example working, budgetary, relationship or lodging issues) because of the pandemic or lockdown measures.[20]

Limitations of the study:

1. Small sample size
2. Study was for a short span of time
3. The study was only a one-time survey

Recommendations:

1. This study can be performed on a larger sample size
2. The duration of the study can be longer

Conclusion

Work related pressure is a major task for working ladies in the lockdown. As quantities of working ladies are expanding in training area, they need to manage difficulties like long working hours, job challenges, lack of oversight, poor relationship with partners, remaining task at hand, role struggle, lack of chance for development and progression and occupation disappointment. Also, it isn't just critical to distinguish reasons of pressure and to bargain with them however to empower solid work and diminished dangerous parts of work. Instructive establishments need toconsider the requests of adjusting worry among working ladies to make nature increasingly steady, which will be useful to hold gifted, able and experienced working ladies. The board must work for preparing and instructing, coaching, consistent picking up, directing, open doors for profession improvement, procedures of time the board to deal with their outstanding task at hand at home along with work spot to inspire them to take higher duties. The fundamental discoveries of the study show that all the respondents have trouble because of individual and hierarchical sources. Dealing with the everyday home exercises, kid care and caring for the family individuals are the central point which cause trouble among the working school ladies.[1]

Integration of Health Education and Cultural Value of Bimanesse Called "Maja Labo Dahu" toward the Intention to Stop Smoking of Smoker Student at Bima District-Indonesia

Martiningsih[1], Nurul Inayati[2], Rini Hendari[1], Ade Wulandari[1]

[1]Mater of Science Nursing, Department of Medical Surgery Nursing Department, Mataram Health Polytechnic (Poltekkes Mataram), Bima 84112, West Nusa Tenggara-Indonesia, [2]Master of Health Analyst, Mataram Health Politechnic (Poltekkes Mataram), Mataram 83232, West Nusa Tenggara-Indonesia

Abstract

Socio-cultural elements may affect someone to follow or leave a behavior. Cultural values in the Bima District-West Nusa Tenggara Province community that are in line with health behavior are the cultural values called "Maja Labo Dahu/MLD", "Maja" means self-aware and "dahu" means carefulness. This study aims to determine the effect of integrating the cultural value of "MLD" and health education toward the intention of high school student to stop smoking in Bima district . This study is a quasy experiment with pre-post-test with control group design with purposiv sampling on 60 students of 5 Senior High School in Bima district. Self report was used to analyze the intention to stop smoking. Data analysis was examined by using Pairred T-Test. The results showed 86.7% had strong intention to stop smoking and 13.3% had weak intention. The mean standard pre-post deviation in the treatment group was 4,633 ± 8,046 with a p-value <0.001. It can be concluded that there was a significant effect of interventions integrating MLD cultural values and health education toward the intention of student to stop smoking. Therefore, "Smoking session" efforts are required by considering elements of local culture and family resources.

Keywords: *Education, Cultural Values, Intention to Stop Smoking.*

Introduction

The overview Smoking behavior of adolescents in our country is very worrying. One-fifth of Indonesia's population aged between 13-15 years have smoked and have tried cigarettes for the first time at the age of less than 10 years. Three out of five Indonesian students aged 13-15 have been exposed to cigarette advertisements and can easily buy cigarettes[1]. In the world, smoking is the highest cause of death and disability, because smoking is the main behavioral risk factor associated with Cerebro Vascular Desease (CVD) besides hypertension, unhealthy diets, high cholesterol and air pollution[2]. Based on this, it is important for the government to try to stop the increase in new smokers/prevent the addition of new smokers if we want to reduce the number of teenage smoking and educate the younger generation about the effects/dangers of smoking.

It is important to make collaboration in order to educate young people such as students. The government through the Ministry of Health of the Republic of Indonesia with the youth health program has made various efforts but needs to be supported by various parties. The research suggests the need to promote health prevention of early smoking behavior among adolescents including involving the school. This becomes the basis for the need for literacy to bring up the intention to stop smoking for adolescents who have/just started smoking[3]. In line with research on high school students in the district of Bima,

Phone Number: 081237327111

the number of high school students who smoke is around 15% of the population. This figure is quite high besides it confirmed by the fact that the majority of teenagers start smoking since junior high school/junior high school and even elementary school/elementary school[4]. Therefore prevention of risk behavior and changing risk behavior into health-supporting behavior through education, especially for adolescents/adolescence, is important in the long-term preventive effort that is sustainable and synergizes with programs that support health and consider the elements of local cultural values.

Bimanesse society define culture as something that is associated with behavior, in this case health behavior is the cultural value of "*Maja LaboDahu*/ MLD". MLD cultural value contains two components which are interrelated and complementary[5]. Based on this, this study was conducted to analyze the effect of the integration of health education and the cultural value of Bimanesse culture *"Maja Labo Dahu"* on the intention to stop smoking in high school student smokers.

Materials and Method

This research was a quasi-experimental conducted in the district of Bima West Nusa Tenggara Province in August-September 2019. The respondents were the 10-12 grader of high school students from 3 state high schools, 1 vocational high school, 1 madrasa aliyah (Islamic high school) and the sample selection was purposive sampling with a total of 60 respondents divided into two groups. The treatment group was given health education using a booklet entitled "Self Confidence and Achievement without Smoking" which contained the integration of health eduaction about the health hazards of smoking and the cultural value of MLD (ISBN 978-623-91626-7-2) while in the control group provided health education using the booklet of the Ministry of Health of the Republic of Indonesia in 2017 entitle "Healthy Living without Cigarettes". Health education in each group was carried out for 4 meetings (1 meeting/week). The evaluation of quit smoking intention variables used quitting intention questionnaire and self report on smoking behavior. The research instrument consisted of 24 question items on the Linkert scale and validity and reliability tests were conducted. The results of the validity of the quitting intention questionnaire used in this study were 0.855>0.4227 with a Cronbach's Alphareability test value of 0.734. Processing and data analysis used SPSS 16 software with pairred T Test.

Results and Discussion

Results: Characteristics all respondents were male as many as 60 people (100%) from locations in 5 High Schools (SMA). The others variables can be seen in the table below:

Table 1. Characteristics of age and Risk Factor CVD Based on history of Alcohol use and family smoker Based on Groupbased on group (n = 60)

Characteristics	Treatment group (n=30)		Control group (n=30)	
	n	%	n	%
Age, year				
15	8	26.7	4	13.3
16	15	50.0	12	40.0
17	6	20.0	12	40.0
18	1	3.3	2	6.7
Age; mean standard deviation, min-max, median (year)	16	0.79	15-18	16
Do you have family member that is addicted of smoking?				
No	15	50	14	46.7
Yes	15	50	16	53.3

Based on the data in table 1 all respondents with an average age of 16 years (age range 15-18 years). CVD risk in the treatment group: based on alcohol use behavior 30% had tried and used alcohol and 53.3% had families smoked.

Table 2. The intension of quitting of smoking before and after giving education on treatment and control group (n = 60)

Variabel	Treatment group (n=30)				Control group (n=30)			
	Pre		Post		Pre		Post	
	n	%	N	%	n	%	n	%
The intension to quit of smoking								
Less	12	40	4	13.3	14	46.7	9	30
Good	18	60	26	86.7	16	53.3	21	70

Based on table 2. in the treatment group before MLD education showed that 12 people (40%) had less intention to stop smoking and 18 people (60%) had good smoking cessation intentions whereas after MLD education there were still 4 (13.3%) with intention to quit smoking less smoking and 26 people (86.7%) with good smoking cessation intentions.

Table 3. Distribution of mean the intension quit smoking of smoker student before and after giving education on treatment and control group in DISTRICT of Bima (n = 60).

The intension quit smoking	Mean,SD	Min-Max	Mean pre-post, SD	95% CI	p-value
Treatment Group					
• Pre	76.27±5.452	65-88	4.633±8.046	74.23 – 78.30	<0.001
• Post	80.85±6.063	60-90		78.47 – 83.00	
Control Group					
• Pre	76.21±6.772	63-88	4.467±6.425	73.81-78.61	0.005
• Post	80.73±6.379	56-91		78.59-83.11	

Based on table 3, it shows that the difference in the mean of the first and second measurements in the treatment group is 4,467 with a standard deviation of 8.046. The p-value is< 0.001, so it can be concluded that there is a significant difference between pre and post education measurements in groups that get health education integrated with MLD cultural values.

Discussion

In this study, risky behavior in intervened adolescents is smoking behavior by integrating the cultural values of MLD and health education "No smoking" so that it is expected that adolescents have the knowledge and awareness which further becomes a stimulus and has a strong intention to stop smoking. Findings The results of this study indicate that integrated health education with local cultural values in this case MLD cultural values have a significant influence on the strong intention to stop smoking in high school students in the district of Bima. This study is as relatively same as the results of Herawati, et al., 2017 research which suggests the need for health promotion of adolescents who have/just started smoking. Thus, it is the basis for the need of literacy to bring up the intention to quit smoking. In line with the research of Akmal, et al., 2016 in high school students in the district of Bima entitle "Attitudes Influencing the Intention to Stop Smoking in High Schools students in the district of Bima" which suggest the need some efforts to prevent risk behaviors or change risk behaviors into health-supporting behaviors including through education especially in adolescents/adolescence. This becomes important in the long-term preventive efforts that continue to be sustainable and synergize with programs that support health and consider local cultural value elements.

The results of the bivariate analysis of the intention to quit smoking before the MLD education of adolescents with the intention to quit smoking less as much as 40% while after the MLD education decreased to 13.3% compared to the control group before the education of adolescents with the intention to quit smoking less as much as 46.7% while after education decreased to 30%.

This shows that although there was a similar decline, there were more smokers in the treatment group who had stronger smoking cessation intentions than in the control group. This means that health education integrated with the local cultural value of "MLD" which is the cultural value of the Bimanesse society influences the emergence of intentions and increases motivation to quit smoking. In accordance with the results of research that a person will follow or leave a behavior influenced by socio-cultural elements and a strong intention to stop smoking is influenced by subjective norms that are believed by individuals[4].

Based on the Big Indonesian Dictionary/KBBI published by the Ministry of National Education, being ashamed means feeling very uncomfortable (despicable, inferior, etc.) for doing something that is not good (not right, different from the habit) and afraid that can be interpreted as piety; reluctant, not brave (doing something that is not appropriate[6]. The meaning according to KBBI is in line with the meaning of the word MLD in the Bimanesse society. The word "Maja" means shame and "Dahu" means Afraid. If we review the above words semantically or meaningfully, "Maja" (shame) means that people or people of Bima will be ashamed when doing something outside of God's corridor, whether it is crime, sin, etc. whether related to humans or to God. "Dahu" (afraid), almost have the same interpretation process as the word Shame. Equally afraid when committing a crime or badness. In adolescent smokers who get integrated health education states that education with a health hazard approach to the effects of smoking alone is not enough to sensitize because of a sense "Excessive confidence" in his health status and adolescent age, so an additional approach cultural values as general values that apply in social life and society are more easily accepted and obeyed.

Characteristics of smoking behavior in this study 83.3%, were active smokers in the last 6 months with the age of the firstly smoking started at the age of 10 years -14 years and 16.7% started smoking at the age of less than 10 years. This is consistent with the results of research related to smoking behavior in Indonesia according to the Global Youth Tobacco Survey/GYTS, (WHO, 2015) that every year there are 16.4 million new smokers age between 10 and 19 years. So efforts to reduce the number of teenage smokers, prevent new smokers and educate young people about the effects and dangers of smoking are very important to save Indonesia's future generations from cardiovascular epidemics[7]. The age of first smoking at the age of 16-18 years, significantly increases the risk of the incidence of hypertension independently (people who smoke for the first time at the age of 16-18 years will immediately become regular smokers, ie people who smoke at least 1 cigarette/days, not smoking anymore as a trial and error. According to the results of research that shows that as much as 51.3% of CVD sufferers mostly start smoking at the age of adolescents. Based on these findings it is necessary to implement policies to promote healthy lifestyles in children and adolescents is very important for the prevention of CVD Healthy behavior is learned from childhood and continues into adulthood[8].

In addition, it is necessary to strive to increase the role of the government in carrying out a strategy of cultural approach that is safe and acceptable to the community[9] and working with educational institutions and increasing the accessibility of adolescents to health promotion programs carried out using community approaches in educational institutions that proven to have a positive effect on changes in adolescent health behaviors[10]. The results of other studies indicate that Fear and Embarrassment or "Maja Labo Dahu" are values that need to be integrated in Education teaching materials. This will complement each other's successful educational process in schools[5]. In the end all of the above efforts are expected to have a positive effect with changes in adolescent health behavior.

Conclusion

Integrated the cultural values "MLD" and health education about the dangers of smoking affect the strong intention to stop smoking in high school students. Integrated and programmed education based on local cultural values in high school as an effort to initiate the intention to quit smoking influences giving stronger stimulation to increase smoking cessation intention so as to then can encourage efforts to to Intention Quit Smoking and avoid risky behavior among adolescents. Continued efforts are needed in the literacy of the prevention of smoking behavior in adolescents at an earlier age level (elementary school and junior high school) taking into account local cultural elements and the resources available at school.

Application of Poskestren as Health Promotion Strategy for Improving Clean and Healthy Behavior of Pesantren in East Java Province

Maygi Restu Yang Esa[1], Muhammad Baharuddin Wisudawan Putra[2], Diyah Werdiningtyas, S.Gz[3]

[1]Undergraduate Student in Department Health Policy and Administration, Faculty of Public Health, Universitas Airlangga, Surabaya, Indonesia, [2]Undergraduate student in Department Health Promotion and Behavior, Faculty of Public Health, Universitas Airlangga, Surabaya, Indonesia, [3]Government employees in Sub Sector of Health Promotion and Community Empowerment, Field of Public Health, Health Department of East Java Province, Indonesia

Abstract

Islamic boarding schools (Pesantren) are Islamic educational institutions in Indonesia. The Ministry of Health of the Republic of Indonesia has launched a concept to encourage people to care about their health, namely the Clean and Healthy Behavior (PHBS). Islamic boarding schools also have health problems so they need attention in efforts to improve public health. The health effort undertaken at the Pesantren is Poskestren (Pesantren Health Care). Based on the Health Department Data of East Java Provincial (2019), there are 3,965 islamic boarding schools with 1,284 Poskestren in East Java province. Poskestren can be a solution in solving health problems in Pesantren. Therefore the Poskestren must be arranged properly. In health promotion there are health promotion strategies which consist of advocacy, community development, community empowerment and partnerships. This health promotion strategy can be a reference in the implementation of the Poskestren in Pesantren.

Keywords: *Pesantren, Poskestren, PHBS, Health Promotion Strategy.*

Introduction

Islamic boarding schools (Pesantren) are Islamic educational institutions in Indonesia. Pesatren can be said as one of the centers of gathering people who live together and carry out activities together so that it can be said to be an environment that is at risk of disease transmission. The highest diseases that can occur in pesantren include scabies, ARI, and gastritis.(1) This can occur due to personal hygiene and poor environmental sanitation.

The Government of Indonesia through the Ministry of Health has launched ten indicators of clean and healthy behavior (PHBS). PHBS covers five settings, one of which is PHBS in schools/educational institutions. Pesantren as one type of educational institution needs special attention in the implementation of PHBS as an effort to improve the health status of residents in their environment.

Community empowerment is one of the health promotion strategies. Poskestren is a manifestation of community-based health efforts (UKBM) carried out in Pesantren. Poskestren prioritizes promotive and preventive services without neglecting the curative and rehabilitative aspects with the guidance of the Primary health care (Puskesmas).

Based on the Health Department Data of East Java Province (2019), there are 3,965 boarding schools with 1,284 Poskestren in East Java province. The Governor of East Java Province launched the East Java Santri Healthy and Blessing Program (SAJADAH) which is an effort to assist the Pesantren. The aim is to increase the level of independence of the Poskestren and PHBS in the pesantren environment. This assistance involved various sectors ranging from the pesantren community, the health office, the puskesmas and other partnerships.

Based on the description above, the researchers conducted a study related to the effectiveness of the

Poskestren assistance program in increasing PHBS in the Pesantren of East Java Province.

Method

This research uses quantitative research method with a secondary data analysis approach. This study uses data sourced from Health Department of East Java Provinceand also the policy for the implementation of the Pesantren assistance program. Data processing in this study used the test of two non-parametric paired samples with the Wilcoxon test. Secondary data used ordinal scale by looking at the PHBS classification data before and after getting the Pesantren assistance program.

Result

Overview of the Achievement of the Poskestren Assistance Program (SAJADAH) in East Java Province: According to Health Department Data of East Java Province (2019), East Java Province has 3,965 Pesantren with 1,284 Poskestren. This shows that there are 32.38% of pesantren that have Poskestren. The following is a comparison chart of the number of pesantren and the number of Poskestren in the District/ City of East Java Province:

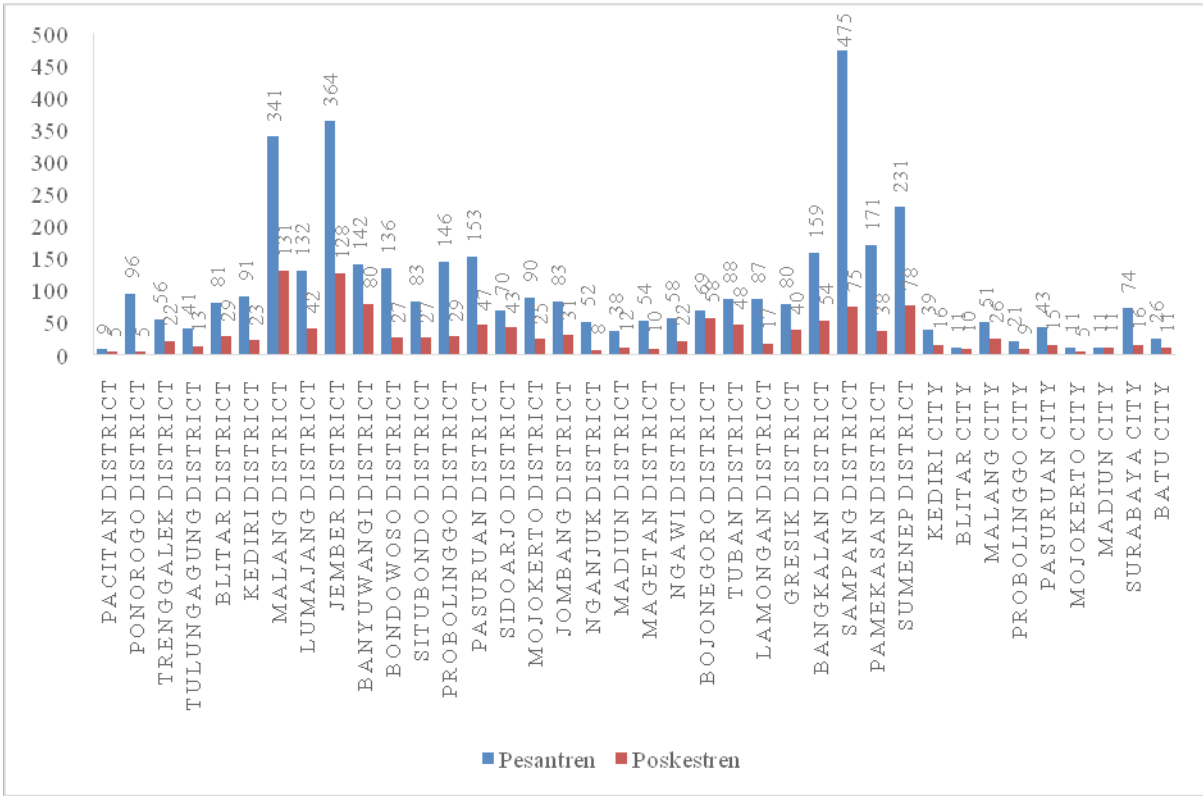

Figure 1. Number of Pesantren and Poskestren in District/City in East Java Province in 2019

Figure 1 shows that not all pesantren have Poskestren. This shows that health efforts in Pesantren in each region have not been running optimally. For example in Sampang District which has 475 Pesantren but only has 75 Poskestren (15.79% of the total number of Pesantren).

PHBS scores were collected to find out the Poskestren classification. There are four classifications. The first classification is the Poskestren which has a value of one to five. The second classification is the Poskestren which has a value of six to ten. The third classification is the Poskestren which has values of eleven to fifteen. And the fourth classification has a value of sixteen to eighteen. Following are the success rates in (%) of the Poskestren assistance program for improving the classification of PHBS in East Java Province in 2019:

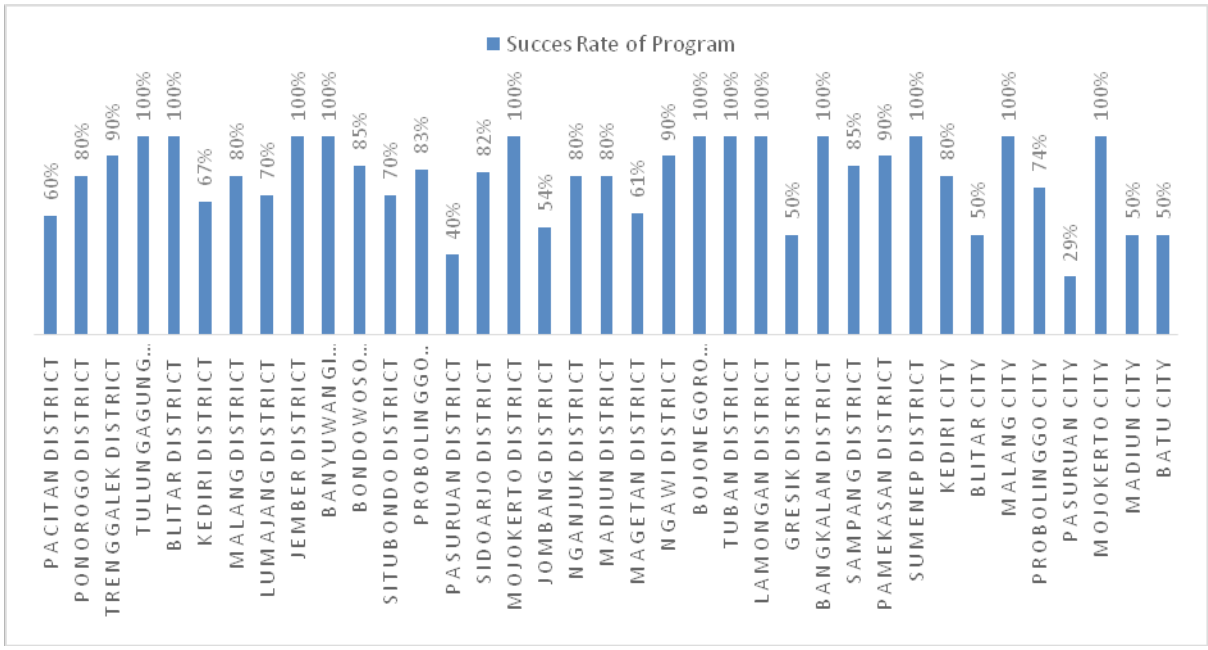

Figure 2. The Success Rate of the Poskestren Assistance Program Against PHBS in East Java Province in 2019

Figure 2 shows that there are 12 districts or cities that have increased PHBS by 100% with the Poskestren Assistance Program. There are only two districts or cities that have not reached a success rate of 50%. The processed data shows that the data are not normally distributed (sig 0.0000 <α 0.05) so that the difference test for two Non Parametric Paired samples (Wilcoxon Test) is used. The Wilcoxon test results are sig 0,000 <<α 0.05. It can be concluded that there are differences in Clean and Healthy Behavior (PHBS) between before the Poskestren Assistance Program and after the Poskestren Assistance Program. This shows that the assistance program for Poskestren was effective and succeeded in increasing PHBS in Pesantren.

Discussion

Poskestren as a Health Promotion Strategy in Pesantren: There is a relationship between the role of the poskestren and the Personal Hygiene behavior of adolescent santri in Al-Ghazaalie Islamic Boarding School Kranjingan, Sumbersari District, Jember District. [3]. But there are also many other factors that influence this behavior.

Another study said that the health status of santri in a Pesantren that has a Poskestren is in a fairly good category consisting of three health sub-variables namely physical health in the good category (100%), mental health in the pretty good category (63%), and health the social category is quite good with a percentage of 43.8%.[10] Therefore, every Pesantren needs to establish a Poskestren because if the Poskestren is run well, the health of the santri will improve, especially at the level of implementation of the Clean and Healthy Behavior (PHBS) of the santri.

Poskestren is present as one of the health promotion strategies in Pesantren. However, the existence of the Poskestren cannot guarantee that PHBS in the pesantren is good. A strategy is needed to run the Poskestren. The strategy in question is a health promotion strategy.

Health promotion strategies are based on the complexity of the nature of people's behavior. Based on the Decree of the Minister of Health No. 1114/MENKES/SK/VII/2005 concerning Guidelines for Implementing Health Promotion in the Regions, health promotion is an effort to increase the community's capacity through learning from, by, for and with the comunity, so that they can help themselves, and develop community-based activities, in accordance with local socio-culture and supported by health-oriented public policies.

To achieve the above objectives, the health promotion strategy implemented at the Poskestren contains four aspects.

1. **Advocacy:** Advocacy is an approach and motivation towards certain parties which is calculated to be able to support the successful development of PHBS both in material and non material aspects. The parties involved are both formal and informal community leaders who generally act as resource persons (opinion leaders), or policy makers (norms) or funders. Other certain parties can also be in the form of society or mass media that can create a conducive atmosphere, public opinion and encouragement of the creation of community PHBS.

   The factors influencing the success of the poskestren were knowledge, participation, motivation & support, leadership, community potential, cooperation, and policy.[7] While the failure factors in the Poskestren program were weak community participation and the emergence of a dependency towards the Ministry of Health assistance and District Health Office. This shows that Poskestren's internal commitment and external support for Poskestren affect the success of the Poskestren itself.

   Policy is an example of the commitment of policy makers in an issue. Some regulations have been established by the government in the procurement of Poskestren as an effort to improve the degree of public health, especially in the pesantren environment.

   Supporting regulations and policies include:

   1. Regulation of the Minister of Health of the Republic of Indonesia Number 1 of 2013 concerning Guidelines for Organizing and Developing Poskestren which are guidelines for implementing Poskestren.
   2. Joint Decree of the Minister of Health, Minister of Religion, and Minister of Home Affairs Number 1067/Menkes/SKB/VIII/2002, Number 385 of 2002, and Number 37 of 2002 concerning Improvement of the Health of Pesantren and Other Religious Institutions
   3. Joint Decree of the Minister of National Education, Minister of Health, Minister of Religion, and Minister of Home Affairs Number 1/U/SKB/2003, Number 1067/Menkes/SKB/VII/2003, Number MA/230A/2003, and Number 26 of 2003 about the Development and Development of School Health Enterprises.
   4. Minister of Health Regulation No. 2269/Menkes/Per/XI/2011 concerning Guidelines for the Development of Clean and Healthy Behavior (State Gazette of the Republic of Indonesia Number 755, 2011) which states that Pesantren are one of the targets of PHBS in educational institutions.
   5. The program issued by the Governor of East Java in the form of SAJADAH which is an effort to assist Poskestren in East Java Pesantren.

2. **Social Support:** Community development is an effort to create a social environment that encourages individuals in community members to want to do the behavior that is introduced. Individual community members will be more motivated to engage in introduced behavior if community leaders or influential people in the environment approve or support the introduced behavior.

   To achieve the objectives of fostering and enhancing the functions and performance of the Poskestren, the Puskesmas carries out several activities as the person responsible for the Poskestren in its area. The puskesmas started the formation of the Poskestren by coordinating with the leaders or managers of the Pesantren to approach it. This approach aims to prepare members of the pesantren so that they are willing to support the implementation of the Poskestren. Furthermore, the Self-Inspection Survey (SMD) was conducted involving members of the Pesantren. Puskesmas staff, and related stakeholders. The purpose of SMD is to recognize and identify health problems in the pesantren environment so that they can be considered in what interventions to take. The Puskesmas will also provide guidance and monitoring to help manage the Poskestren on a regular basis.

   Improving services at the Poskestren must be based on the health needs of the pesantren community. Therefore there needs to be support for the availability and skills of the Poskestren resources. The Puskesmas assisted with the Pesantren apparatus will also form a Poskestren cadre called SantriHusada. SantriHusada together with the manager of the Poskestren who will later become the spearhead in moving the pesantren community to care about health. This will be the embryo of empowering the Pesantren community by developing and empowering the potential or resources of the Pesantren itself.

Based on the Wilcoxon test it was stated that there were differences in PHBS between before and after the Poskestren assistance program (SAJADAH). This is consistent with a research that there is a significant relationship between self-sanitation and environmental sanitation socialization innovations through poskestren with santri attitudes towards sanitation.[11]Socialization of self and environmental sanitation through poskestren is in the high category where socialization provides knowledge about self sanitation and the environment for students. In addition, socialization makes students more active in implementing cooperation in maintaining personal hygiene and the environment of the pesantren where they live and study.

3. **Community Empowerment:** In health promotion, community empowerment is a very important part. Empowerment is the process of providing information to health promotion targets continuously and continuously following the development of targets, and the process of helping targets to change from not knowing to knowing (knowledge aspects), from knowing to being willing (attitude aspects), and from wanting to be able (practice aspects) carry out the introduced behavior. Therefore success in empowerment is to make the target understand and realize that something (a health problem) is a problem for him and for the community so that it leads to the application of the introduced behavior.

   Poskestren can be a facility for pesantren communities to obtain health information. Through the managers of the Poskestren and SantriHusada, information can be given continuously and continuously. This is because they live together directly so they understand the development of health problems in Pesantren. Health information from the Puskesmas and other health media is expected to be received by the Poskestren Manager and SantriHusada which can then be passed on to the Pesantren community. The puskesmas will also conduct regular training with the aim of implementing the Poskestren to provide information and intervention to the pesantren community appropriately.

4. **Partnership:** Partnerships must be promoted well in order to support the other three aspects of health promotion strategies. The partnership is based on the principles of equality, openness and mutual benefit. Partnerships with other individuals or groups will enable the implementation of the Poskestren to be even better.

   Partners from Poskestren can support the implementation of Poskestren by providing resource assistance. The resources provided can be in the form of financial resources, materials, information, coaching and training. Stakeholders who can be an opportunity to become a Poskestren partner include Government Agencies or Institutions such as ministries of religion and health, Community Leaders, Community Organizations/NGOs, Business or private sector and Universities.

   The government as the policy maker can play a role in formulating health-oriented policies to support health activities and programs in Pesantren. The government can also provide facilities in the form of cross-sector meeting and discussion. This can enable and assist Poskestren to establish broader partners.

   Community leaders and organizations involved such as in the religious field can be a companion to the Poskestren. Human resource assistance can help in health improvement programs run by the Poskestren. This is because the Poskestren, Pesantren and Community Leaders/Community Organizations have emotional closeness to the Pesantren community. So that health programs or interventions carried out in solving health problems can be received with an appropriate approach.

   The business or private sector has obligations related to social responsibility (CSR). Increasing the role of CSR can be an opportunity to improve the degree of public health. Businesses or the private sector can be involved in health promotion efforts such as involvement and assistance with the implementation of the Poskestren.

   Higher education in Indonesia has Tri Darma Higher Education as its basic principle. One of the Tri Darma of Higher Education is “Community Service”. The role of tertiary institutions is very clear to be able to make people equal in solving problems in their environment. The academic community can help the community through education and research to develop solutions or appropriate interventions for a problem. This can be an alternative for Poskestren to obtain information and human resources sources in intervening in health problems in Pesantren.

Conclusion

The results of the Poskestren analysis as a health promotion strategy in the East Java Pesantren can be summarized as follows:

1. Poskestren Assistance Program (SAJADAH) is effective and has succeeded in increasing PHBS in Pesantren in East Java Province.
2. Advocacy becomes very important in health interventions by involving policy makers to make regulations and health-oriented references. The establishment of the Poskestren is based on health problems that often occur in Pesantren boarding schools.
3. Community Development becomes important to provide facilities to the Poskestren in its implementation. Starting from the preparation, planning, organizing and control stages.
4. Poskestren becomes a place for Pesantren community to manage their potential to improve the health status of Pesantren community. Therefore, Community Empowerment through Poskestren must be fostered and developed continuously to promote health and reduce morbidity.
5. Partnerships are needed to optimize the implementation of the Poskestren itself.

Recommendation:

1. Promoting the Poskestren program based on the Health Promotion Strategy and the needs of the pesantren community in the Pesantren of East Java Province.
2. The government and the person responsible for the Poskestren should bridge the Poskestren with the Business World or Private partnership.

Conflict of Interest: The authors have no conflict of interest with the material presented in this paper

Perception of Successful Aging in Nursing Students

Mihyeon Seong

Department of Nursing, Changshin University. Assistant Professor, RN, MSN, PhD

Abstract

The purpose of this study is to apply Q methodologies to identify and understand the type of successful aging perception in nursing students. The study organized the Q population through in-depth interviews to select 21 Q samples that could represent the Q population by coordination with two professors and researchers familiar with the Q methodology, and 49 nursing students were selected as P-samples. The data collection was about three months from September 10, 2020 to September 17, 2020 and was analyzed using the PQ Method Program. According to this study, nursing students perception of successful aging was divided into four types: Type 1 "capitalism type," Type 2 "Self-esteem type," Type 3 "Adaptive type," Type 4 "Stable type". As a result of this study, the four types of nursing students recognized health, leisure, economic power, and self-esteem. This study, understanding of each type of subjective aspect should be enhanced, and a wide range of insights should be provided so that nursing students can establish a value system of humanity and nursing professions in the undergraduate program in the future. In addition, it is expected that it will be used as a basic material for nursing education that can grow into a nurse who can meet the national expectations as a health care manager for the elderly through education that can develop the ability to cope with various problems faced in the nursing field.

Keywords: *Nursing students, Successful Aging, Q method, Subjectivity.*

Introduction

The rapid growth of the elderly population is a trend of the elderly, and Korea is already an aging society, and it is expected by 2026, and it is on the faster side compared to other developed countries[1]. Due to this, achieving aging without the elderly is the main aging in all countries, which is contrary to the existing increase in aging that is positive, which involves emphasizing the positive meaning of everything and actively acting on avoidable fears. Another new paradigm is being demanded for healthcare and welfare systems[2].

A better understanding of an aging society can help to better understand the problems facing the elderly and their families[3]. The deaths of relatives and friends, separation from children due to marriage, employment, and anatomical changes make older people more vulnerable to various risks, so focus on ideal and purposeful life, close contact with others, and self-esteem We need to find ways to improve it [4,5]. However, the successful concept of aging in Western society does not adequately reflect the socio-cultural values of Korea[6]. Since successful aging is a value-oriented aging, it can be said that it is a socio-psychological concept that reflects the overall life of humans and reflects various social conditions that are culturally common to the elderly in that society. It is important[7-9]. Therefore, most studies on successful aging in Korea consist of the elderly, and studies related to the successful aging of nurses or nursing students who need to take care of such elderly are hard to find.

Looking at the latest research, nursing students' perception of successful aging is the only study of the effects of the self-elasticity and family elasticity of nursing students in Yang and Song[10] on the perception of successful aging. A comparative study of successful aging perception among Korean and Japanese university

students[11], There are studies by Park and Lee[12] that examine the difference between the perceptions of successful aging among the elderly and college students, and studies related to aging among college students are studies on aging anxiety, which is a relatively negative emotion, and studies on successful aging, a positive concept, are insufficient. In particular, nursing students can easily feel the overall atmosphere of society by being exposed to various values of home and society and easily accepting changes in their surroundings as a grace of their self-identity during college[10,13]. In addition, the department of nursing must be able to respond appropriately to the rapidly changing aging society and adapt to the field of nursing, where the main goal of nursing is changing to the elderly[10].

However, despite these changes in the times, current nursing students are lacking in awareness of the paradigm that reflects social and medical changes and preparation for the future society. It is necessary to grow into a nurse who can meet national expectations as an elderly health manager through education that can cultivate coping skills in various problem[14]. In addition, a positive attitude toward the elderly affects the quality of nursing and is an important issue for nursing practitioners[15], The positive concept of successful aging, recognized by prospective nurses who will work in the field of nursing in the future, can be a driving force in approaching elderly patients as decent care targets. It can be said that it is urgent to first explore the perception of successful aging among nursing students.

Therefore, this study investigates successful aging, which is a positive concept of aging, for nursing students who are prospective medical personnel and are responsible for supporting and nursing the elderly population using the subjective Q methodology. This study was conducted to explore the perception of aging. The Q methodology focuses on the first person point of view to understand the phenomenon of successful aging from the perspective of individual nursing students, and through this, it is expected that various perspectives on successful aging can be identified. In addition, the purpose of this study is to derive various subjective perceptions of the successful aging of nursing students and to enhance the understanding of the successful aging of nursing students. It identifies subjective types and serves as the basic data needed to research and develop effective nursing strategies in an ultra-aging society.

Research Purpose: The purpose of this study is to explore the types of recognition of successful aging of nursing students and their characteristics by applying the Q methodology to grasp the subject's subjective perspective. The specific research objectives are as follows.

1. Type the perception of nursing students' successful aging.
2. Analyze and describe the characteristics of nursing students' perception of successful aging by type.

Research Method

Research Design: This study is an exploratory study applying the Q methodology, a subjectivity study method, to systematically and scientifically explore the perception of aging in nursing students.

Research Subject: The subject of this study is to understand the trend of successful aging subjectively perceived by nursing students. It is a P-sample that can best reveal successful aging, and was targeted at nursing students enrolled in the Department of Nursing in City C. In order to form the Q population, a total of 50 subjects including 3 subjects who participated in the interview were conveniently sampled, and 50 subjects who were recruited through the recruitment announcement explained the purpose and procedure of the study and received voluntary consent for the study. The study explained that the subjects can withdraw from the study at any time they do not want to participate in the study, and that there is no penalty. A total of 49 P-samples were used for the study, excluding one who responded insult to the questionnaire.

Research Process:

Composition of Q population and Q sample: In this study, the Q population was formed based on the collected data by reviewing the literature on successful aging and conducting in-depth interviews with nursing students.

The subjects of the in-depth interview to obtain the Q recruitment group on the successful aging of nursing students are three nursing students aged 20 to 29 who are enrolled in the nursing department located in C city. It was selected as a target.

The in-depth interview on the perception of successful aging of nursing students was conducted for about 3 days from September 10, 2020 to September 13, 2020, and a total of 75 Q recruitment groups

were extracted. In the Q population extracted on the successful aging of nursing students, a researcher and two nursing professors participated together to readjust the sentences, exchange opinions several times, and then select 21 Q samples (Table 1).

Q sorting: It took about 30 minutes for the Q classification, general characteristics investigation, and interview, and the Q sample classification period was implemented from September 14, 2020 to September 18, 2020. For classification of Q samples, a final Q sample is written on a paper card (Q-card), and each Q statement card is read by a research participant. It was divided into three parts. After completing the classification into three groups, the statements of the Q statement card group classified as agreeing were read again, and the Q statement cards were sorted in order from the most agreeing (+3) to neutral (0). Similarly, the Q statement card group classified as disagreeable was classified from the most disagreeable (-3) to neutral (0), and arranged according to the card arrangement distribution table shown in <Figure 1>. After the classification was completed, we tried to obtain useful information when interpreting the Q factor through questions related to reasons, feelings, and successful aging for each statement. While the subject was performing Q classification, the researcher sat near the subject, instructed the classification method, and collected data on general characteristics such as age, gender, and religion. It took about 30 minutes for the Q classification, writing questionnaire, and interview.

Data Analysis: This study was analyzed using the principal component analysis of the PQ method program, and the specific analysis method is as follows.

1. 21 Q statements were entered with -3 to 3 points assigned to each P sample depending on the level of consent or disagreement.
2. In order to determine the most ideal number of factors, the most appropriate one was selected based on an Eigen value of 1.0 or higher.
3. The standard score for each type (Z-score) and the average of the standard scores for each type were analyzed.
4. Strong consent items (Z-score 1.00 or higher) and strong disagreement items (Z-score -1.00 or higher) by type were extracted and analyzed.
5. In order to analyze the reasons for selecting consent items and non-consent items of each type, general characteristics, questionnaire data, and statements of the subject were considered together to comprehensively analyze the characteristics of the types.

Results

Analysis of results: Six of the 49 subjects in this study (P-11, 15, 23, 29, 45, 48) were not classified as one factor because the difference in factor weights was not significant. The age ranged from 20 to 23 years old (Table 2).

According to the characteristics of each type, the four types of recognition of successful aging of nursing students in this study were' capitalism type' with 23 students for type 1, 7 for type 2,'self-esteem type', and type 3 for 'adaptive type', 4 types were classified as' stable' into 5 persons. The Eigen Value by type of this study is as shown in (Table 3), and the explanatory power was 58%. In addition, the correlation coefficient between types 1 and 3 was the highest at r = .49, and the correlation coefficient between types 3 and 4 was slightly lower at r = .07 (Table 4).

Q type analysis:

Type 1: Capitalist type: Type 1 subjects said that health and economic requirements were more important than their appearance and wisdom for successful aging (Table 5). In particular, they recognized that health and happiness will follow if capital is satisfied.

Looking at this in detail, the statements of respondents with the first type of representativeness (factor weight 1.0 or more) are as follows.

The epitome of this type, P-21 (factor weight = .90) says, "In a capitalist society, there is nothing that should be money. The basis for successfully aging must also have capital. You must have your hobbies, your health and your money." Said. Through this, in this study, type 1 with these characteristics was named' capitalism type'.

Type 2: Self-esteem type: Type 2 subjects said that the aspect related to self-esteem is important for successful aging (Table 5). They value the maintenance of sexual function, the success of their children, and interpersonal relationships, and that their self-esteem is more important than the economic requirements.

Looking at this in detail, the statements of respondents with the second type of representativeness

(factor weight 1.0 or more) are as follows. Typical of this type, P-30 (factor weight = .73) said, "It is important to be confident without money. What can be envious of others in old age? It is important to have children's success, a strong sex life, and a friend or spouse who can be with them when they need help or are bored."

Through this, in this study, type 2 with these characteristics was named' self-esteem type'.

Type 3: Adaptive type: Type 3 subjects said that adaptation according to the life cycle is important for successful aging (Table 5).

In particular, they said that they should not be afraid of changes due to aging, act at times, adapt and manage even if there are changes in the body, and devise a plan to live happily.

Specifically, the statements of respondents with the 3rd type of representativeness (factor weight 1.0 or more) are as follows. The epitome of this type, P-24 (factor weight = .77), says, "I think it is necessary to adapt flexibly over time. Everyone is aging and cannot reverse it. It is important to go in order." Said. Through this, in this study, type 3 with these characteristics was named' adaptive type'.

Type 4: Stable type: Type 4 subjects recognized that it is important to feel a sense of stability for successful aging (Table 5).

They said that they need a family next to them in their old age, hobbies and housing that can lead to a successful and stable life for the family. In particular, they did not have any dynamic changes in their life after retirement, and they showed a tendency to want a quiet and comfortable life.

Specifically, the statements of respondents with the 4th type of representativeness (factor weight 1.0 or more) are as follows. The epitome of this type, P-24 (factor weight = .74), said, "I only have my own home and retire, but I wish there was no change in life. I hope to maintain my current life and continue my happiness." Said. Through this, in this study, type 4 with these characteristics was named' stable type'.

Table 1. Q Statement

Statement
1. Live happily without worries.
2. There is no economic burden.
3. Have a job.
4. There is no problem with sexual function.
5. There are no special health problems.
6. Children succeed.
7. You have a good relationship with your spouse.
8. I have a lot of friends around me.
9. Honor those around you.
10. There are self-owned houses.
11. I have a hobby.
12. You look young.
13. A experienced people
14. You can get a pension in the country.
15. I get along well with the younger generation.
16. I am not afraid of challenges and failures.
17. I am not afraid of change.
18. Raising grandchildren.
19. You can go on a trip.
20. You are managing chronic diseases well.
21. There is no memory loss.

Discussion and Conclusion

In the undergraduate course of the nursing college, it is necessary to establish a value system of nursing professions with a sense of humanity and nursing ethics, and based on this, education that can cultivate the ability to cope with various problem situations faced in the field is necessary. This study was conducted as part of an effort to manage and solve problems in our society where the current traditional virtue of the path ideology has collapsed and the elderly are directly or indirectly experiencing various [15].

It is believed that the first study of the concept of successful aging recognized by nursing students through this study will serve as basic data for fostering a positive perception of old age.

In this study, four types of nursing students' perception of successful aging were identified as "Type 1: Capitalism", "Type 2: Self-Esteem", "Type 3: Adaptive", and "Type 4: Stable".

Existing studies on successful aging have been mainly searched around old age at home and abroad[2,16] and research on the perception of old age by nurses and nursing students who are mainly caring for the elderly in an aging society. There are not many situations. Therefore, the four types of successful aging of nursing students identified in this study are thought to be able to present the characteristics of successful aging recognized by the younger generation and nursing students, as each type shows the attributes and various characteristics of successful aging. As a result of this study, the four types were analyzed to have properties such as health, leisure,

interpersonal relationships, and economic conditions. Looking at this in detail, types 1 and 4 recognized that economic factors were important. The economic requirements of retirement increase the quality of life by satisfying the elderly's income needs, satisfying the leisure needs through hobbies and leisure activities, and satisfying diverse and complex needs such as health and social psychological needs[17].

According to a study by Han[18], economic capital in old age influences the successful aging of capital formed before old age. Economic stability and security in old age can be the basis for the elderly's autonomous life and self-fulfillment orientation, active participation in life, family, interpersonal satisfaction, and acceptance of others[19], the national pension system or the retirement pension system. It can be said that it is necessary to enlarge the back. This is a part that cannot be overlooked as the elderly who suffer from economic hardships can psychologically contract and interfere with social activities[20].

On the contrary, Type 2 regarded interpersonal relationships as important, but Hong and Lim[21] said that people tend to maintain social relationships built up at work and in society even after retirement, and people with high self-esteem tend to value interpersonal relationships. There was said to be. In old age, it is highly likely that the scope of the social support system will be reduced due to the death of neighbors such as spouses, brothers, and sisters and becoming a nuclear family[22]. Therefore, it is necessary to prepare a nursing intervention plan that can improve interpersonal relationships and self-esteem in nursing practice in old age.

In addition, it was said that type 3 and type 4 should have a hobby to enjoy leisure. Leisure means free time without restraint, and through leisure, it can be an opportunity for self-realization by getting a break from the tension of relationships that occur in retirement life, and restoring the balance of one's life[23]. Leisure goes beyond simply spending time or promoting fellowship, providing an opportunity for the elderly to participate in a positive society, not isolation from society, and an opportunity to experience social support[24]. In addition, leisure satisfaction that can be obtained through leisure activities is an important variable of successful aging[25], Leisure in the life of old age represents a mental state, becoming free from the forced life, becoming the core of human existence, and wanting oneself. It refers to a pleasant state of being connected while doing the selected work[26]. Therefore, leisure has its essence in resolving various and complex mental anxieties caused by the prolongation of life expectancy and the loss of official social roles, and allowing people to feel joy and reward in life[27].

Types 1 and 4 pointed to health as an important factor in successful aging. Health problems in old age negatively affect life in terms of economic, social relations, and psycho-emotional aspects, and in middle age, individuals from the first half of adults to old age due to the effects of accumulated experiences. Because it is the time to make the difference in the health level of women even larger[28,29], intervention measures that appropriately apply recognition should be sought.

Erikson presents self-integration as a major development task to be carried out in old age, sees and accepts one's past, present, and future, resolves conflicts and guilt of the past, organizes life, and achieves self-integration[30]. However, no part of self-actualization was found in the traits of successful aging of nursing students identified in this study. Therefore, the importance of self-integration should be emphasized in the curriculum, including the mediation of successful aging recognized by nursing students. This is considered to be an effective way for nursing students to establish personal standards for successful aging in old age, to achieve self-integration by preparing for old age, and to grow into a nurse who can help achieve successful aging. In addition, it is expected that this study can be used as an institutional device and basic data for education to achieve successful aging in the old age.

Inhibition Activity of Water Hyacinth Leaf Extract (Eichornia Crassipes) to the Growth of Subgingival Plaque Bacteria Colony

Ayu Arismawati[1], Noer Ulfah[2], Lambang Bargowo[2]

[1]Undergraduate Student of Dental Medicine Faculty, Airlangga University, Surabaya-Indonesia,
[2]Lecturer in Department of Periodonsia Dentistry, Faculty of Dentistry, Airlangga University, Surabaya, Indonesia

Abstract

Background: Periodontitis is an infectious disease in periodontal tissue and is able to cause a plaque that contains bacteria on the teeth. These bacteria colonize the oral cavity, invade the periodontal tissue, and attack the body's host system. Indonesia has many floras and one of them is called Water hyacinth. This flora is commonly known as waste because its abbility to pollute the environment. However, water hyacinth has a useful material including alkaloids, flavonoids, and tannins that can be used as the antibacterial agents. The study aims to determine the effect water hyancinth leaf extract (echiorniacrassipes) to the growth of subgingival plaque bacteria colony. Method**:** The study was conducted by using serial dilution techniques in the BHIB media with 100%; 50%; 25%; 12,5%; 6,25%; 3,125%; 1,56%; 0,78% concentrations and planting on MHA medium. The analysis method in this study uses the Shapiro-Wilk Test, Levene's Test, and statistical tests with One-Way Anova.

Results: There are significant differences at the growth of sub gingival plaque bacteria. There is no growth of subgingival plaque bacteriain groups of 100%; 50%; 25%; 12.5% and 6.25%. The growth of subgingival plaque bacteria colonies was only seen at 3.125% concentration and increased the number of bacteria colonies at a 1.56%.

Conclusion: Water hyacinth leaf extract was effective to inhibit the growth of sub gingival plaque bacteria colonies.

Introduction

Periodontal disease and dental caries are two diseases that mostly affect the severity of dental and oral diseases. Tooth loss in adults is a result of the severe periodontal abnormalities and is found in 5-15% of the world's population[1,2].

Periodontitis is an infectious disease in periodontal tissue with various manifestations, starting from inflammation of the gingiva, formation of periodontal pockets, loss of supporting bone until the occurrence of a date tooth[3]. In addition, this disease is also characterized by the inflammation that causes damage to collagen fibers, the gingival matrix, periodontal ligaments, and alveolar bone[4]. Periodontitis is often associated with infections from various bacteria, such as *Porphyromonasgingivalis, Tannerella forsythia* and *Aggregatibacteractinomycetemcomitans*. The occured tissue damage tha is the result of complex interactions of these bacteria with the response of the host as well as the inflammatory process[5].

During the inflammation process, bacterial products are released and penetrate into the periodontal tissues. Afterward, those bacterial products activate the host immunoinflamatory response by producing cytokines and matrix metalloproteinase which can cause damage to the extracellular matrix of the periodontal tissue. The matrix metalloproteinase is a proteolytic enzyme that causes damage to the extracellular matrix, periodontal ligament, and the bone protein matrix. Thereby, MMP plays an important role in the regulation of periodontal tissue damage[6].

Dental plaque is the main factor which causes the early periodontal abnormalities and known as gingivitis – a process of inflammation in the gingiva[7]. Plaque formation begins with the formation of dental pellicles on the clean surface of the tooth in minutes. These bacteria can bind to receptors on the dental pellicle. Initial colonization is started by gram-positive facultative bacteria, such as *A. viscosus, S, sanguis*. This plaque develops rapidly in the early development of the biofilm and progressively slows down during the biofilm maturation[8]. The next stage is secondary colonization by bacteria such as *Prevotellaintermedia, Prevotelleloescheii, Capnocytophagaspp, Fusobacteriumnucleatum,* and *Porphyromonasgingivalis*. These bacteria have the ability to attach at the different species of plaque microorganisms. If the plaque is not cleaned, it will develop into the subgingival area which causes subgingival plaque formation[9].

Nowadays, the modern medical world of the molecular field is very advanced, but this does not stop the traditional medicine to exist. This is proved by the many traditional medicines that are widely used by the medical world to treat diseases. Some plants are known for their antibacterial activity[10].

Water hyacinth is a plant that floats on the surface of the water as well as has thick leaves and air-filled stems which make this plant float. This plant is considered disturbing because it can spread in large areas of the water and cover the surface of the water. Thereby, it can reduce the light that penetrate trough the water and result in reduced oxygen in the water. Other affect include silting the lake or other waters due to water hyacinth that dies and settles on the bottom. But the content of the water hyacinth plants is secondary metabolites of alkaloids, flavonoids, tannins, which known as antibacterial, antiviral, and anticancer[11]. Based on the background, the aims of the study is to analyse the inhibition activity of water hyancinth leaf extract (echiorniacrassipes) to the growth of subgingival plaque bacteria colony.

Material and Method

This type of research is a laboratory experiment with the design of the Post-Test Only control group design[12]. This research was conducted in the Research Center Dental Medicine Faculty, Airlangga University and Pharmacy Laboratory, Airlangga University, East Java.

The tools and materials used are test tubes and shelves, buchner funnel, petri dish, glass gourd, incubator, micropipette, osse, spreader, rotary evaporator, scales, auctoclave, water hyacinth leaf extract (*Eichornia Crassipes*), subgingival plaque bacteria stock, *Brain Heart Infusion Broth* (BHIB) media, and *Mueller Hinton Agar* (MHA)media

Making Hyacinth Leaf Extract: Water hyacinth leaves are dried with oven in 50^{o}C until dry. After the drying process, then the grinding one is conducted using a blender to get water hyacinth powder granule, as much as 600 grams of water hyacinth leaves macerated with 2500 ml ethanol 96% solvent. Moreover, stirred with a stirrer for 24 hours and filtered using whatmann paper which is placed on a Buchner funnel and obtained by filtrate. Centrifuged 50 rpm for 24 hours. The sediment obtained is then evaporated using a rotary evaporator for 4 hours. Finally, the conduct and evaporation above the water bath until finished, and then evaporated again until there is no residual ethanol content.

Stage of Inhibition Activity Test for Water Hyacinth Leaf Extract to The Growth of Subgingival Plaque Bacteria

The inhibitory test in this study uses a liquid dilution method with serial dilution as well as some steps. Firstly, we have to prepare 9 test tubes with 1 test tube containing subgingival plaque bacteria stock which has been prepared and labeled. The test tube no. 1 containing 10 ml of water hyacinth leaf extract, eight other test tubes filled with BHIB media as much as 5 ml. After the other eight tubes were filled with BHIB, 5 ml of extract was put in the tube no. 1 then stirred it. Afterward, 5 ml of liquid from the tube no. 1 were taken and put in tube no. 2 and stirred again. The next one, 5 ml of liquid from the tube no. 2 are taken and put in the tube no. 5. Stirred it again, and repeated until the liquid is put in the tube No. 8. In additiom, the 5 ml of liquid from tube no. 8

is removed so that the liquid in each tube has the same liquid volume.

After all of the media are prepared, 1 ml of subgingival plaque bacteria stock is inserted into each tube containing a mixture of BHIB and the extract. The remaining tubes containing only 5 ml of BHIB media were negative controls, and the tubes containing subgingival plaque bacteriastock were positive controls. All the treatment above was repeated three times to obtain adequate sample size. The tubes were incubated at 37ºC for 24 hours

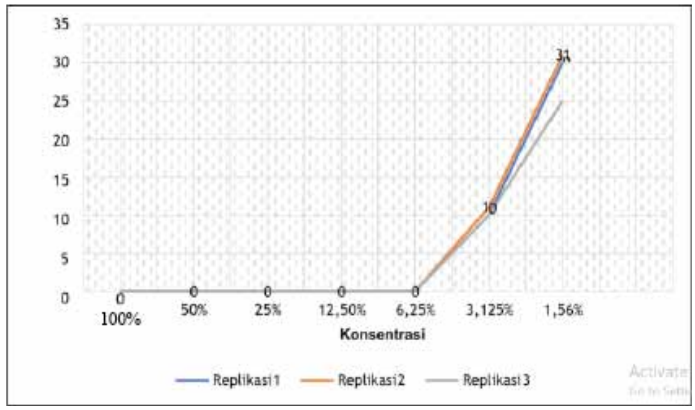
After 24 hours incubated, each tube is taken 1 osse and planted on Mueller Hinton Agar (MHA) media by strike move to check there is bacteria growth or not. Incubation is conducted for 24 hours at 37ºC. After the second incubation, we have to take 0.1 ml from the boundary tube between the bacteria growth and the non-positive. The negative control then planted on the MHA media. Enter it into the incubator at 37ºC for 24 hours. Calculates the number of bacteria colonies that grow on MHA media after the last incubation and do the data analysis.

Results

The results of this study can be seen from the number of subgingival plaque bacteriacolonies growth.

Table 1. The number of subgingival plaque bacteriacolonies given water hyacinth leaf extract (*Eicchorniacrassipes*) at a concentration of 1,56%-100%

Concentrations	1	2	3
100%	0	0	0
50%	0	0	0
25%	0	0	0
12,5%	0	0	0
6,25%	0	0	0
3,125%	10	12	11
1,56%	31	30	33
Positive controls	149	151	152
Negative controls	0	0	0



Concentration

Based on the results of the study it can be seen that there is no growth of subgingival plaque bacteriain groups of 100%; 50%; 25%; 12.5% and 6.25%. The growth of subgingival plaque bacteria colonies was only seen at 3.125% concentration and increased the number of bacteria colonies at 1.56%.

The measurement results are tabulated according to each group sample and followed by testing the normal distribution using the Shapiro-Wilk Test with Sig> 0.05. It can be concluded that the data are normally distributed. Afterward, the homogeneity testing using Levene's Test with Sig. <0.05 can be concluded that the data is homogeneous. Afterward, the statistical tests were conducted using One-Way Anova at the significance level of Sig. <0.05 and significant differences were obtained. Finally, it then continued by performing multiple comparisons using Post-hoc TukeyAnova which concluded that all groups had significant differences.

Discussion

The results of the analysis showed that the number of colonies at a concentration of 3.125% had a significant difference with the number of colonies at a concentration of 1.56% and positive control. Likewise, the number of colonies in the extract of water hyacinth leaves concentration of 1.56% has a significant difference to the number of colonies in the positive control group. This shows that the extract of water hyacinth leaves at a concentration of 3.125% and 1.56% has a fairly good antibacterial effect. The results of this study also showed a bactericidal effect of 6.25% where subgingival plaque bacterial colonies were completely invisible and the

inhibitory power was best at a concentration of 3.125%, where the subgingival plaque bacteria could grow at minimal number. This is due to the presence of bioactive substances in water hyacinth leaves which have been studied as antibacterial, andthe quantity of concentration that contains bioactive substances that play a role in inhibiting bacteria.

Based on scientific research stated that water hyacinth leaf extract contains alkaloids, flavonoids, and tannins which are known to have antibacterial power that can inhibit bacterial growth[10]. The alkaloids contained in the hyacinth leaf extract has antibacterial biological activity that can interfere with the constituent components of the bacterial cell that make the cell wall not formed and easily get lysed[11]. Antibacterial flavonoids has a working mechanism that can interfere bacterial membrane synthesis, and inhibits bacterial metabolism – which can damage bacterial breeding pathways and damage bacterial membrane walls that will be followed by the bacterial death[13]. This compound will also interfere with the energy metabolism in a similar manner to the respiratory systembecause the energy demand for active absorption of various metabolites andthe biosynthesis of macromolecules insufficient so that lead to bacterial dead[14]. Tannin known to has antibacterial activity related to their ability to form hydrogen bonds which results in protein denaturation in the membrane so that cells experience damage. Membrane damage causes the fulfillment of nutrients needed by bacteria cannot be achieved. This can be disrupted the bacterial metabolism and reduce the bacterial energy[15].

Conclusion

Water hyacinth leaf extract was effective to inhibit the growth of sub gingival plaque bacteria colonies. So, it is expected to preserve the water hyacinth plant and cultivate it.

Ethical Clearance: The research process involves participants in the survey using a questionnaire that was accordant with the ethical research principle based on the regulation of research ethic committee. The present study was conducted in accordance with the research principles. This study implemented the basic principle ethics of respect, beneficence, nonmaleficence, and justice.

Institute and Research Centre, Sumadeep Vidyapeeth Deemed to be University (An Instituton), Waghodia, Pipariya, Vadodara, Gujarat, India

Abstract

Background: A hernia is protrusion of a tissue or an organ such as omentum or bowel loops through a defect in the weakened abdominal wall muscles . Amongst the various types of hernia, inguinal hernia is the most commonest. The best modality of treating an inguinal hernia is surgery and hence most common surgery done is inguinal hernia repair . Amongst the various techniques of hernia repair, Lichtenstein's tension free meshplasty is the latest, best and has become the gold standard . In 2008, COVIDIEN launched progrip mesh which is a self fixating mesh used in both inguinal and incisional hernia repair . Progrip mesh is made up isoelastic lightweight macroporous knitted monofilament polypropylene fabric that incorporates resorbablepolylactic acid fabric on one side of the mesh to provide self fixation during first few months of implantation.

Aim: The aim of this study is to compare the outcome on basis of incidence of postoperative pain and operative time of self fixating pro-grip mesh with conventional mesh in Lichtensteins open inguinal herniomeshplasty .

Objective:

- *Comparing outcome in terms*
- *Post-operative pain*
- *Operative time*

Conclusion: Lichtenstein's open inguinal herniomeshplasty using self-fixating Progrip mesh has an advantage over conventional mesh repair as it requires less operative time and the incidence of postoperative pain is less frequent and occurs at an even more later period compared to conventional mesh repair which at times is found to be present even at post-operative day 2.

Keywords: *Lichtensteins Inguinal herniomeshplasty, self fixating Progrip mesh.*

Introduction

An inguinal hernia occurs when any tissue,protrudes through a weak spot in the anterior abdominal wall muscles . Amongst the types of hernia, the most common type is inguinal hernia . And the best modality of treating an inguinal hernia is surgery .

Inguinal hernia can be repaired either in its old traditional modality of open hernioplasty or its new modality of laparoscopic hernioplasty . But each

Phone: 9426345105

technique has got its advantage and disadvantage, despite that the main goal of any hernia repair is to provide the best and strongest repair, least recurrence rate, least possible discomfort and quickest recovery.

In open method hernia can be managed by:

- Herniotomy
- Herniorraphy
- Hernioplasty

Laparoscopic repair is the recent advancement. It can be done by 2 ways with mesh fixation and without mesh fixation and can be by two approaches :

- Total Extra Peritoneal (TEP)
- Trans Abdominal Preperitoneal (TAPP)

Inguinal hernia repair still remains a problem because of chronic groin pain following mesh repair.

One of the most commonly performed surgical procedures is inguinal hernia repair but despite being most common it is associated with long term risks of pain and discomfort. In 1996, according to a study done by Cunningham et Al, he was the first to report 63% pain incidence after one year [1] . In a large cross sectional cohort study the rate of chronic pain was 29% at around 5 years following the surgery.

The mesh is supposed to be a foreign body implanted into our body which resulted in loss of myelinated axons, axonal, peri and endoneuronaledema and subsequently pain[2] . The method of fixation may be an inportant causative factor for pain . For fixation most commonly used is the sutures which may cause ischaemia or nerve damage which eventually leads to pain . Mesh implantation can be done by several techniques, but the most commonly involved technique is by sutures to anchor the mesh in position and prevent its migration, curling and wrinkling. But these sutures that anchor the mesh can cause extensive tissue tension and nerve entrapment which are considered to be leading causes to prolonged post-operative pain, which is the main primary objective to be looked in our study . This problem does not solve even on application of absorbable sutures instead of non-absorbable ones.

The new progrip mesh is Isoelastic large-pore lightweighted, knitted, monofilament polypropylene fabric that incorporates microgrips which are resorbable and these only provide self-gripping fixation. It promotes the regeneration of healthy tissue inside its microgrips and shows low rate of complications with 100% self fixation [3] [4] . Hence our present study is to enlighten the advantage of this self grippingprogrip mesh in reducing the incidence of chronic groin pain after inguinal hernia repair and reduce the operative time as it leads to less exposure to anaesthetic drugs.

Materials and Method

The prospective study was conducted between July 2019 to June 2020 and around 20 patients were divided into two groups with inguinal hernia and were admitted to Dhiraj General Hospital, S.B.K.S.M.I.R.C, Pipariya, Vadodara, Gujarat, India.

Inclusion Criteria:

Patients diagnosed with inguinal hernia and planned for lichtensteinsinguila hernia repair

Willing for study

Anaestheticaly fit patients .Exclusion criteria :

- Patient not willing for study.
- Paediatric age group patients
- Patient not fit anaesthetically.

Method of collection of data: This study involves 20 patients coming with cheif complaints of swelling in the inguinal region. Detailed history and clinical examination was done. Written and Informed Consent was obtained for taking part in study and for operative procedure. Patients were randomly divided into two groups A and B, each group containing 10 patients each.

Group A patients were planned for Lichtenstein's repair with conventional mesh.

Group B patients planned for Lichtenstein's repair with self fixating pro-grip mesh.

Time period starting from skin incision to placing and fixation of mesh in each group will be noted.

Post-operative pain were noted according to pain score during post operative hospital stay and after discharge on 15th day and 3 months of follow up

Procedure:

Pateint in supine position following spinal anaesthesia

Parts painted and draped: Skin incision placed approximately 1.25 cm above an imaginary line joining pubic tubercle and anterior superior iliac spine.

Skin and subcutaneous tissue incised and external oblique aponeurosis identified .

Small incision placed over the EOA along the fibres

External oblique aponeurosis opened upto the superior inguinal ring medially and deep inguinal ring laterally .

Inguinal canal opened and space created upto conjoint tendon medially and upturn part of inguinal ligament laterally .

Spermatic cord identified, stretched and lateralisation of cord structure done .

Defect identified of size approximately 2x2 cm through which hernial sac was protruding .

Inferior epigastric artery identified and found to be lateral to the hernial sac (direct inguinal hernia) .

Hernial sac identified and reduced and posterior wall repair done with prolene no. 1 R.B .

Progrip mesh was taken after creating good space underneath and around the spermatic cord

Figure 1: Showing usage of progrip mesh for hernioplasty

Master suture taken on pubic tubercle with blue mark on pro-grip mesh with prolene 1-0 R.B and the mesh spread properly.

All layers re sutured back as opened

EOA sutured in continuous fashion with prolene 2-0 R.B and artficial superficial ring created

Subcutaneous layer sutured with vicryl 2-0 R.B

Skin sutured with ethilon 2-0 R.C with subcuticular technique

Sterile dressing done after attaining hemostasis

Patient shifted to post op room as was vitally stable

Discussion

The Lichtensteins tension-free technique has gained remarkable popularity as it is easy-to-perform with less tissue dissection[5]. But questions concerning the safety of implantation of mesh for longer duration and the risk of chronic pain have always been around . Various studies have reported the rate of prolonged pain after inguinal hernia surgery to increase from 9.7% to 51.6%[6]; and the incidence of persistent postoperative pain is reported to be as high as 6% which hinders with daily activities of the patient.

The reason for such pain is unclear . But it can be due to:

- Mesh material that is its structure and interaction with tissue

- Scarring
- At times nerve damage
- Entrapment by sutures

Because of these facts, fixation of the mesh with sutures during surgery continues to be an important factor to be thought and discussed about.

Hence a new self-gripping mesh (Progrip) has been developed in 2008 by COVIDIEN .

This self-gripping mesh is made of: Isoelastic large-pore lightweighted, knitted, monofilament polypropylene fabric that incorporates microgrips which are resorbable and these only provide self-gripping fixation in the initial few months of implantation[7].

The microgripsare: 1-mm projections that are club in shape and are made up of polylactic acid which is biodegradable.

The microgrips integrate for upto 0.5 mm into the tissue and provides stronger tissue incorporation at almost around 5 days.

Hence because of these features available in the self fixatingprogrip mesh can be placed in position safely and proper without the requirement for sutures which can penetrate underlying tissues and might damage cutaneous nerves[8].

Result

Operative time : Conventional mesh repair on an average takes around 35.5 minutes starting from skin incision to closure, whereas progrip mesh repair takes only around 20 mins .

Postoperative pain : as noted in these patients, after conventional mesh repair the GROUP B complaints of chronic pain even after 3 months . Whereas in GROUP A progrip mesh repaired patients they were pain free after post operative day 2 and on follow up after 3 months.

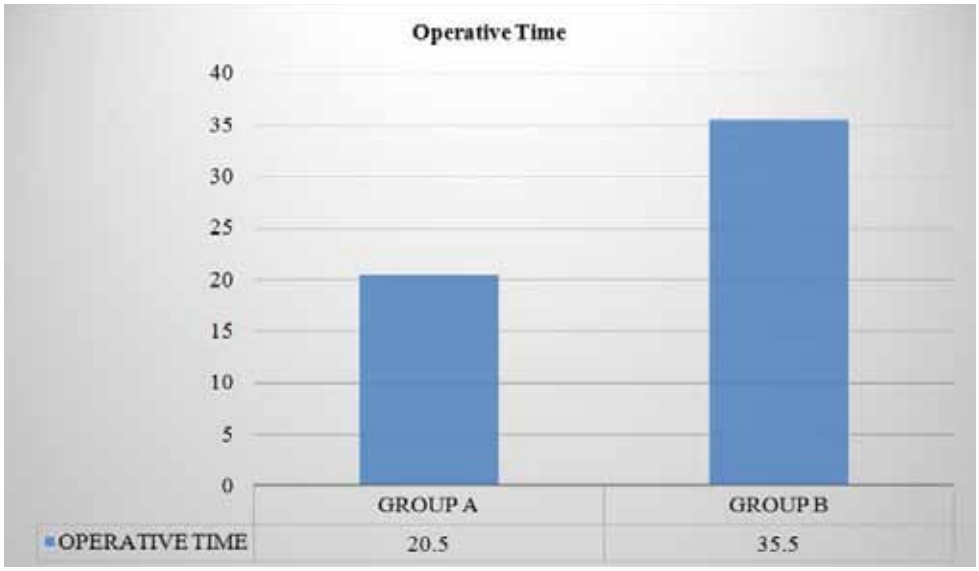

Figure 2: Showing time variation between the operative time between conventional hernioplasty and usage of progrip mesh.

Conclusion

Lichtenstein's open inguinal herniomeshplasty using self-fixating Progrip mesh has an advantage over conventional mesh repair as it requires less operative time and the incidence of post-operative pain is less frequent, mostly painless and occurs at an even more later period compared to conventional mesh repair which at times is found to be present even at post-operativd day 2.

TMEM121 Protein Is a RegulatIon Factor in the Proliferation Activity of the Adrenocortical stem/Progenitor Cells

Mohammed Abdalmalek Ali Al-Bedhawi

Scholar researcher, Institute of Genetic Engineering and Biotechnology, University of Baghdad, Iraq

Abstract

Several studies have identified adrenocortical sub-population cells located in the capsule/sub-capsular area, carrying the aspects of stem/progenitor cells. We previously recognized a novel protein (Tmem121) highly expressed in in this sub capsular area and also highly co-localised with Ki67 in this area. The suggestion of these previous studies was considered to clone and transfect Tmem121 into adrenocortical stem/progenitor cells studying the proliferation changes in the transfected cells. Adrenocortical stem/progenitor cells were isolated and cultivated *in vitro.* The cells were previously isolated and prepared for testing the effect of Tmem121 after three months of *in vitro* cultivation. Specific primers were used to detect and amplified the coding sequence of the TMEM121 using RT-PCR followed by cloning into pIRES2-ERFP vector. Immunocytofluorescent tests were carried out to detect the forced expression of TMEM121 into these cells. Real time PCR assays were followed with specific primers to detect the synchronization of Tmem121 expression with two proliferation markers Ki67 and proliferating cell nuclear antigen (PCNA). Immunocytofluorescent tests results showed a significant expression of TMEM121 into these cells. Real time PCR results showed a significant increase in the expression of both proliferation markers Ki67 and (PCNA). These results suggested a propagating effect of TMEM121 to the adrenocortical stem/progenitor cells.

Keywords: *Tmem121, proliferation, adrenocortical stem/progenitor cells, PCNA and Ki67.*

Introduction

Adrenal cortex have been suggested to have a clusters of undifferentiated cells in the capsule and sub-capsular area with limited steroidogenic capacity in mice[1] and humans[2]. These cells have shown a relatively high proliferating activity and suggested to represent the stem/progenitors cells that responsible of replenish the adrenal cortex[3]. More recent studies also suggested these cells occupied the capsule and the sub-capsular areas as a stem/progenitor neich[4-6].

Although Tmem121 was a poorly studied protein, recent findings regarding its role have been developed. Tmem121 is a member of a family are highly expressed in most embryonic tissues[7]. A wound healing study showed that Tmem121 is one of the genes that contribute to cell proliferation and migration in human endothelial cells[8]. However a recent study forced its expression into MDA cell line but showed no significant effect on the proliferation activity of these cancer cells (un-puplished data). A histological study showed high expression of Tmem121 in capsule and sub-capsular areas of the adrenal cortex with relatively high co-expression of Tmem121 with Ki67 on the adrenal sections [9]. These finding suggested study the effect of cloning and transfection of Tmem121 in more specific cells as adrenocortical stem/progenitor cells to investigate its role in the proliferation activity.

Materials and Method

Experiments that conducted in this study were in agreement with all the guidelines and regulations of the committee on experiments of the school of biomedical sciences, University of Reading, UK.

Animals: Adrenal glands used in this study were freshly isolated from adult Wistar-rats (weight 250-350g) from Harlan Envigo UK were housed in rooms where the ambient temperature and light were under automatic control. The rats were treated under the United Kingdom Home Office Animals Act 1986. Rats were euthanised by CO_2 asphyxiation.

RNA isolation, cDNA synthesis and RT-PCR: TRIzol reagent (Ambion) was used for the isolation of RNA from rat adrenals following the protocol previously described [10]. For synthesis of total cDNA, a RevertAid First Strand cDNA synthesis kit was used. PCR was used to detect the expression of the Tmem121, as well as amplifying its full coding sequence. PCR was used to target transcript variant X1, mRNA (accession number is XM_006225896.3) using specific pair of primers. These primers were designed with NCBI primer design tool. The reaction mixture of PCR included 25µl of 2x master mix of Extensor Hi-Fidelity PCR which mixed with, 1µl of (10µM) Forward primer 5`-3` GCAGGACCTCGTCCCGCTTT That positioned in the sequence (194-217) and 1µl of (10µM) Reverse primer 5`-3` TAGTCCAGCGTCTGTGCGGC that positioned in the sequence (1252-1233)). PCR conditions for this reaction were as follows: 94°C for 1 minute for the initial denaturation and, followed by 36 cycles of 94°C for 20 seconds for denaturation, 59°C for 20 seconds for primer annealing, finally the extension at 72°C for 3 minutes. After cycling, PCR products were separated by electrophoresis on a 1% (w/v) agaros gel with 1kb plus ladder (generuler). The targeted bands were excised and the DNA purified from the gel using QIAquick Gel Extraction Kit (Qiagen).

Tmem121 gene cloning: The amplified segment of the Tmem121 was applied to the next PCR to add the restriction sites that required for cloning. Primers for this PCR were new and designed to have the same sequences in addition to restriction site sequence and CGC or GCG platform up-stream the primers. The two restriction sites of the two primers were chosen carefully to set the gene of interest correctly in the vector (pIRES2-ERFP is a modified version of the pIRES2-ERFP) and not cut through the gene sequence. The EcoR1restriction sequence (5'-GAATTC-3') was added upstream the Tmem121 forward primer and the HindIII restriction sequence 5'-AAGCTT-3'was added upstream the reverse primer. Primer sequences for cloning Tmem121 gene into pIRES2 ERFP vector were: EcoR1-forward primer (5' GCGGAATTCGCAGGACCTCGTCCCGCTTT 3') and HindIII -reverse primer (5' CGCAAGCTTTAGTCCAGCGTCTGTGCGGC 3').

The components of the cloning PCR reaction were mixed as described previously using the PCR product of the first PCR as DNA template. The targeted band of the Tmem121 was excised and the DNA purified.

Digestion, ligation and transformation of competent cells: Both the plasmid and insert were digested with the two restriction enzymes (Promega), The components were assembled in a total volume of 20µl using 2µl of 10x 10X MULTI-CORE™ Buffer (Promega), The reactions were mixed and then incubated for 2-4 hours at 37ºC in a water bath. The digested DNA was profiled by agarose gel electrophoresis. The targeted bands of the digested vector and the digested gene of interest were excised and purified. Ligation reactions were carried out using T4 ligase (Promega) to ligate the gene of interest to the pIRES2-ERFP vector. This addition of the DNA insert and vector was conducted using a 3:1 (insert: vector DNA) molar ratio. The reactions were mixed and incubated overnight at 4°C. Ultra Competent" cell (Mach1™ *Escherichia coli (E. coli)* were prepared.

Purification and sequencing of insert-vector complex: The blue-white screening was conducted for identifying recombinant bacteria that contained the plasmid of interest. Plasmid DNA was isolated using Midiprep purification kit according to the provider's recommendations. The purified complexes were sequenced. Ten microliters of the purified plasmid (100ng/µl) were submitted to Source BioScience for sequencing in both directions using the appropriate primer sites located in pIRES2-ERFP vector.

Adrenocortical stem/progenitor cell preparation: Adrenal cortex cells were isolated following the method previously described by Al-Bedhawi, (2018)[10]. The cells were dispersed in minimum essential media (MEM) containing 0.6 mg/ml collagenase type I (Worthington) and pancreatin (Sigma) 0.5 mg/ml. After each digestion the enzymatic activity was inhibited by the addition of 10% foetal calf serum (FCS) to the medium. Cell viability was assessed using trypan blue The isolated cells were maintained in culture medium at 37°C in humidified atmosphere of 5% CO_2 in air. Magnetic Activated Cell Sorting (MACS) was used to isolate target cells that were expressing Thy-1 using Thy-1 antibody attached to Pierce NHS-Activated magnetic beads following the protocol from the manufacturer.

Transfection of cells with Tmem121: The transfection was carried out using ransfection reagent (TurboFect) after cloning of Tmem121 into pIRES2 ERFP vector. As well as transfection with the plasmid only without insert (native-plasmid) as controls. Cells were 70-80% confluent at the day of transfection. The

efficiency of the transfection was examined using an inverted fluorescent microscope (Inverted Epifluorescent Microscope AXIO) to evaluate the rate of the transfection

Immunocytofluorescence: Dual Immunocytofluorescence assays were conducted to confirm the transfection efficiency and the expression of Tmem121 pattern in the Thy-1 cells (stem/progenitor adrenocortical cells). Cells were incubated with the primary antibodies: Thy-1 antibody, diluted to 1.5µg/ml and Tmem121 1:200 dilution (ab151077) overnight at 4°C. The cells were washed with PBS (3x), incubated with 546 or 647 Alexa-fluor conjugated secondary antibody at a 1:200 dilution for 30 min before washing with PBS (3x). The coverslips were mounted with DAPI (VECTASHIELD). In the immunocytofluorescence both primary and secondary antibodies (mouse and rabbit) were mixed together in the primary and secondary incubation steps, respectively.

Real time PCR assays: Two-step quantitative RT-PCR (RT-qPCR) was employed to detect changes in the gene expression of Tmem121, and the proliferation markers Ki67 and PCNA after the transfection of Tmem121 to the target cells. Cells were collected after 2 and 4 days of transfection. The RNA was isolated from the transfected cells using RNeasy mini kit (qiagen). The isolated RNAs from the biological replicates were mixed together before conducting the cDNA synthesis. Equal RNA concentration (400ng) was used to make the first-strand cDNA. qPCR reactions were set up to analyse the gene expression as fold changes using the ΔΔCt method in comparative quantification. β-Actin was the housekeeping gene in this experiment. qPCR primers were designed. The details of qPCR primers are in (Table 1). The reaction of each well was set up as follows: 0.3µL primers mix (5µM) each, 7µl of 2x quantiTect SYBER Green PCR master mix (Qiagen) and 6.7 µl of the diluted cDNA. The qPCR program was as follow: initial denaturation at 95°C for 15 minutes was used and then 40 cycles of 95°C for 15 seconds followed by 60°C for 1 minute. The final step was to show the melting curve of the products. qPCR was performed using a computerized AB Applied Biosystem.

Table 1: List of primers (Invitrogen) used in the RT-qPCR, their accession number, position in the mRNA sequence and their product size.

Gene	Forward primer 5`-3`	Reverse primer5`-3`	Fragment Size (bp)	Accession number
β-Actin	CACCCGCGAGTACAACCTTC	CCCATACCCACCATCACACC	207	NM_031144.3
Tmem121	GCCTTAGATCTGCTGGATCTGC	CCCTTGCATACTGACCTCACTG	159	XM_006225896.3
Kia67	TTCCAGACACCAGACCATGC	ACTGGTCTTCCTGGTTGTGG	89	XM_006230453.2
PCNA	AGGACGGGGTGAAGTTTTCTG	AGCAAAAGTTAGCTGAACTGGC	134	NM_022381.3

Statistical Analysis: Results of RT-qPCR data were analysed using Dunnett's Multiple Comparison Test of one-way analysis of variance (ANOVA).

Results and Discussion

RT-PCR experiments were successfully carried out to amplify the whole coding sequence of Tmem121. RNA isolation from rat adrenals was achieved with concentrations ranged from (0.8-1.2µg) with high purity. Aliquots of RNA were used for cDNA synthesis followed by PCR to amplify the full coding sequence of Tmem121using specific primers. The amplified amplicon was successfully detected, excised and purified from agarose gel after electrophoresis. The purified DNA band of Tmem121 was used as template in a second PCR using specific primers of same sequences in addition to restriction site sequence and platform up-stream the primers. The resulted PCR product was profiled on agarose gel electrophoresis, which showed a single band represents the full coding sequence of Tmem121 flanked by the EcoR1 restriction sequence and HindIII restriction sequence to be ready for digestion with those two enzymes.

The Tmem121 insert were successfully cloned into the vector and all negative and positive controls were prepared as well and successfully applied to competent

cells for transformation. Plasmid-insert complex was successfully detected in the transforms colonies, which was purified with midiprep kit. The purified vectors were used to transfect the adrenocortical stem/progenitor cells with transfection reagent (Turbofect). The transfection efficiency ranged from 35-60%. Although, Turbofect is a strong cationic polymer efficiently used for transfection, this low-medium transfection efficiency rate (35-60%) resulted from the refractory nature of the primary cell[11].

Immunocytofluorescent: The results of the dual Immunocytofluorescence assays were showed the co-expression of the Tmem121 in the transfected cells (as confirmed by the vector reporter (red fluorescent) confirming the successful transfection in the stem/progenitor cells identified with anti-Thy-1 antibody in comparison with control cells (Figure 1).

Although Thy-1 cells in this study were used after spending three months in cultivation, they were potentially young stem/progenitor cells because they hold similar proliferation rate to these cells in their niche, which were proliferate more constantly and can survive longer *in vitro* [10] in comparison to the whole adrenal primary culture which tends to lose their survival ability after 100 days in vitro[12].

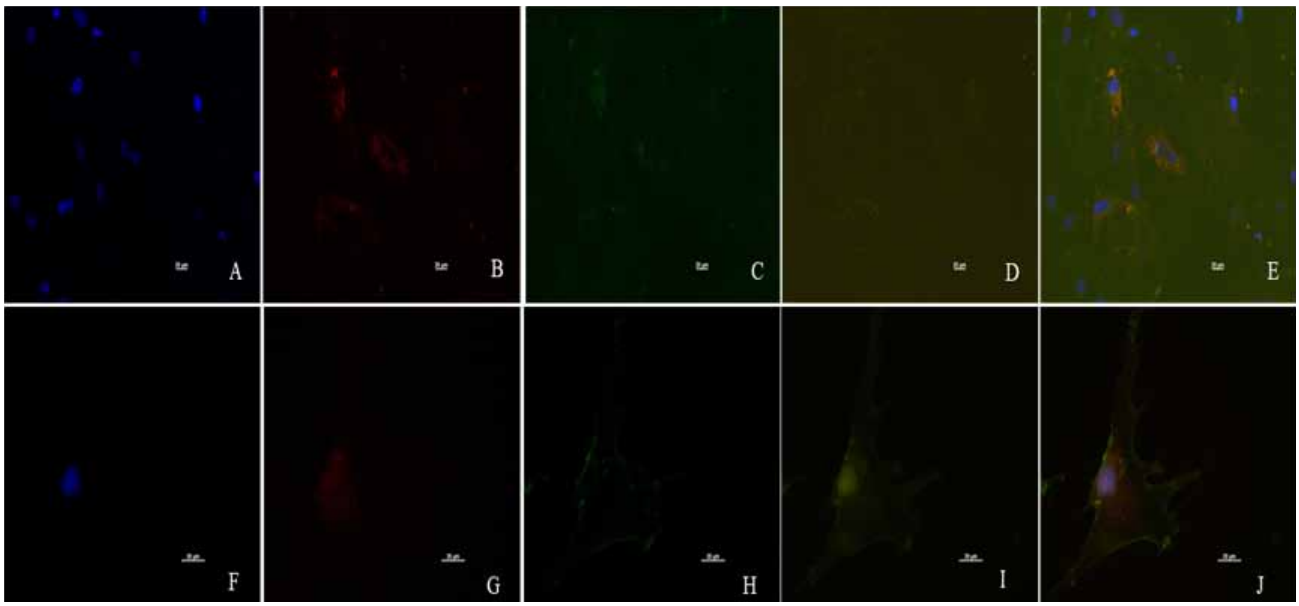

Figure 1: Dual-immunocytofluorescence on three months old cultures of stem/progenitor adrenocortical cell (Thy-1cells). Cells were transfected with native pIRES2-ERFP vector (A-E). Cells were transfected with Tmem121 gene cloned into pIRES2-ERFP vector (F-J).

Cells were fixed and incubated with primary rabbit anti-Tmem121 antibody (ab151077) before detection with secondary anti-rabbit Alexa 546 in D and I. cells also were incubated with mouse anti-Thy-1 antibody before detection with secondary anti-mouse Alexa 488 in C and H. All samples were mounted and cell nuclei were stained with DAPI in (A and F). Red fluorescent protein resulted from pIRES2-ERFP vector in B and G. Merged images of (A), (B), (C) and (D) are shown in (E) and of (F), (G), (H) and (I) in (J). Scale bars: 20µm.

RT-qPCR: The transfection of Thy-1 cells with the coding sequence of Tmem121 gene showed significant responses in both proliferation markers Ki67 and PCNA as measured using two steps-Real time PCR. The control group of this assay were the cells that transfected with native-plasmid which also compared with un-transfected cells in addition to the cells received the Tmem121 gene. The results showed a significant ($P<0.05$) and ($P<0.01$) increase in the expression of Tmem121 two days and four days after transfection respectively (figure1). This result revealed the gradual elevation in the gene expression of Tmem121 due to the time required to SV40 promoter in vector to elevate the expression level in the host cell.

The response of both proliferation markers were also increased in synchronising with the elevation of

the expression of Tmem121. Ki67 expression increased in harmony with the expression of Tmem121 which revealed similar significant (P<0.05) and (P<0.01) increase after two and four days of transfection respectively (figure2). Although PCNA also showed positive response to Tmem121 elevated expression, it was less than the response of Ki67. PCNA showed non-significant increase in the expression after two days of transfection. However, after four days of transfection PCNA showed a significant (P<0.05) increase in its expression (figure 2).

These results revealed a positive relationship between the expression of Tmem121 and the proliferation activity of the adrenocortical stem/progenitor cells represented by two proliferation markers. These results were confirming the suggested relationship between Tmem121 expression in capsule and sub-capsular areas of the adrenal cortex with Ki67 [9].

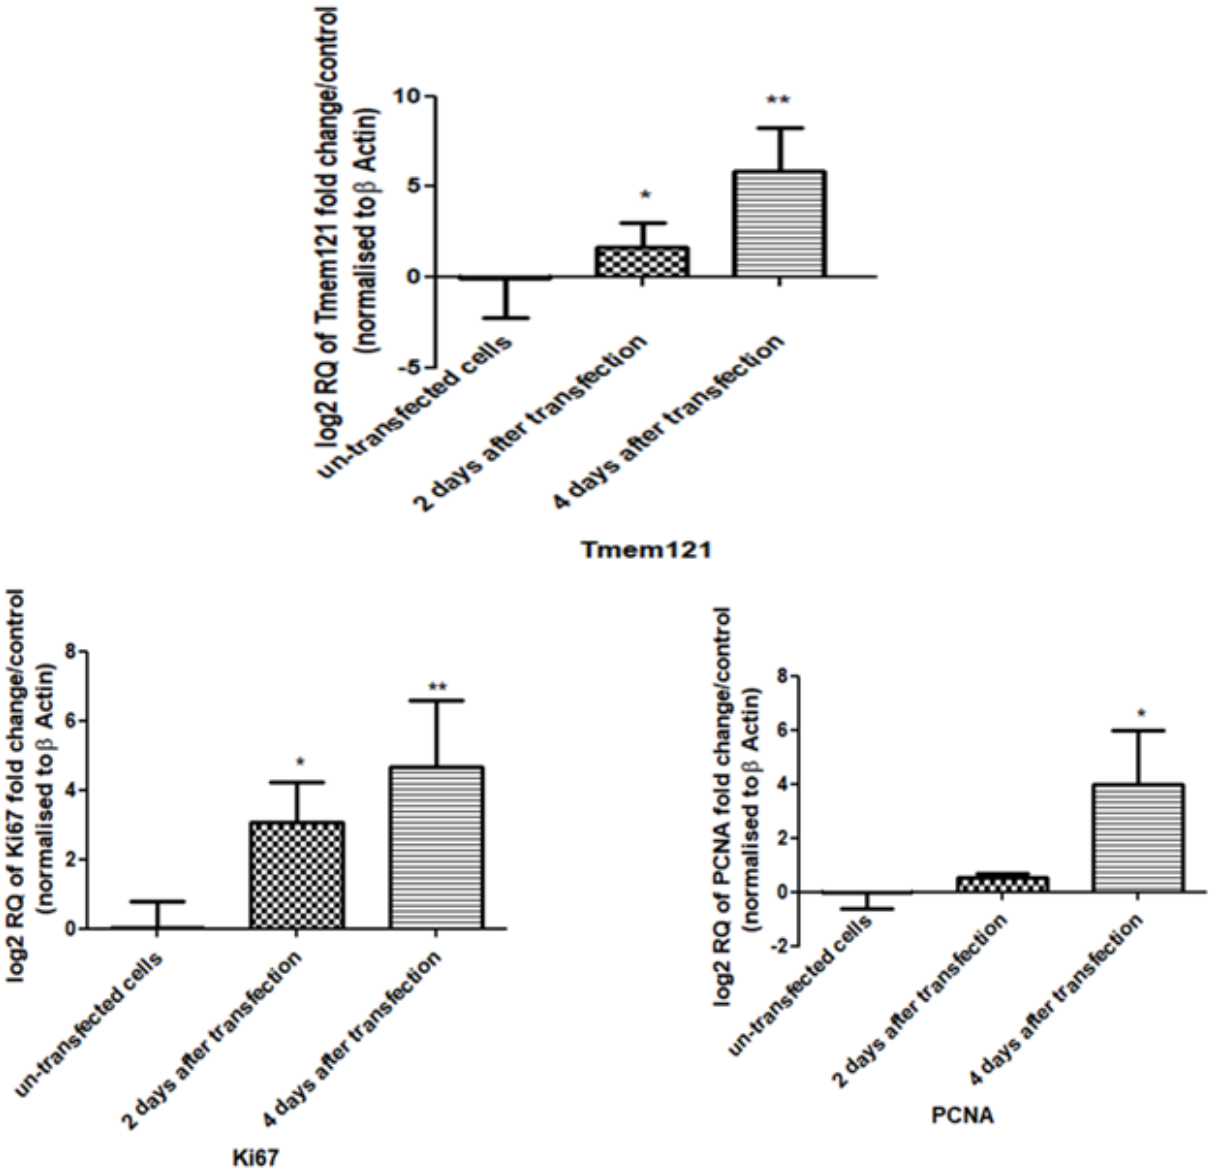

Figure 2. RT-qPCR relative quantification represented fold changes of mRNA expression of Tmem121, Ki67 and PCNA in the Thy-1 cells after Tmem121 transfection. The cells were transfected in their 3rd month of *in vitro* cultivation and the gene expression was then tested at two interval periods 2 and 4 days after transfection. Three biological replicates were used in this experiment. Summarized one-way ANOVA results showed significant * (P<0.05) and/or significant ** (P<0.01) difference.

Conclusion

Elevating the expression of Tmem121 in the adrenocortical stem/progenitor cells by cloning and transfection induce a significant increase in the proliferation markers Ki67 and PCNA. This positive incorporation of Tmem121 with these two markers suggested a propagating effect of TMEM121 to the adrenocortical stem/progenitor cells.

Acknowledgments: We would like to thank all staff and colleague at Hopkins laboratories at University of Reading for their support, training and to have the opportunity to use their labs conducting our experiments. Special thanks to Dr. Andrew Bicknell, Elizabeth Lander and Phil Dash for their support during commencing our research.

Abstract

Background: Broken families It is the family under divorce, separation, death of father, death of mother and death of both parents. It is the legal termination of marriage. It is also the dissolution of marriage that is contracted between husband and wife by the judgment of a court of competent jurisdiction or by an act of the legislature. Separation and divorce have exclusion and negative effects on the behavior of children as well as the burden of education for those in charge of it, which involves risks to the psyche and the degree of coping with children.

Objectives: To determine broken families among secondary school adolescents, assess secondary school's adolescents' behaviors, determine the impact of broken families on adolescents' behaviors, and to find-out the relationship between adolescent's behaviors underbroken family and their socio-demographic characteristics of age, gender, parent's education levels, family type and socio-economic status.

Methodology: Anon-probability (purposive) sample of (555) students, whose age are between 12 to 18 years have been selected; the sampling of study is divided into two stages which include: First stage: the school's selection by cluster, the AL-Najaf City divided to six districts, the schools selected randomly (36) school's boys and girls, from (130) total schools .Second stage: students under broken family selection by using the purposive sampling, while control group from each school students were randomly selected.

Results: Indicate that there is significant relationship between the adolescent's gender under broken family and their behavior domain excessive suffering, poor anger control and poor social conformity. While there is a non-significant relationship between the adolescent's gender under broken family and their other behavior domains. The results show that there is a highly significant relationship between adolescent's Educational level under broken family and their behavior domain poor impulse control and poor anger control. While there is a non-significant relationship between the adolescent's Educational level under broken family and their other behavior domains.

Conclusion: That most of the secondary school's adolescents under broken family have Behavior problems.

Recommendation: To the Governments and Schools should create awareness on the ills of broken homes on the academic, emotional and social adjustments of students through training, workshops and seminars. Parents should be enlightened on the need to stay together as husband and wife to raise a good family.

Introduction

God created mankind and made the production of the offspring and its perpetuity of life through marriage between a man and a woman. Therefore, the family is considered the smallest social institution within the community, and the relationship that binds the father and

the mother within the family, so the more coherent that relationship is, the stronger the society will be, because through the family, the first signs for raising a child and promoting values and good morals are launched[1].

Family is the basic unit of society. A home is that where a family lives which provides children with feelings of security and stability. The members of family constitute the child's first environment for personal and social adjustment. Anything that interferes with these feelings can be regarded as hazardous for adolescents [2].

The effects of a broken family on children depend on numerous factors, including child's age and personality when parents got separated, family relationships and the surrounding circumstances in which changes in the behavior of the child can occur from the simplest detail of the most complex, in addition to the child's ability to overcome these difficulties and favorable conditions [3].

The impact of the broken family on children by shaping children's attitudes, feelings, thoughts, and behaviors, which are manifested by the increase in painful feelings of sadness, anxiety, confusion, fear, guilt, and the reinforcement of misconceptions and behaviors with the domination of some negative ideas that increase the suffering of children when there is an incoherent and disassembled family that has an impact On the quality of life of the adolescents in all areas [4].

Methodology

Design of the Study: A descriptive study is conducted through the period of November 11th, 2018 to May 9th, 2019 in-order to Impact of Broken Family upon Adolescent's Behavior at Secondary Schools in AL- Najaf AL-Ashraf City.

Setting of the Study: The setting of the study includes (36) schools;(12) intermediate schools, (12) high schools (preparatory), and (12) secondary schools, which are distributed in six districts of Al-Najaf Al-Ashraf City, six schools from each quarter's.

Results of the Study

Table (1): Distribution of the Study Sample by their Adolescents Demographic Data

Variables		Broken Family		Control group		P. value
		No.	%	No.	%	
Gender	Male	139	42.0	39	17.4	0.0001*

	P. value	0.185						0.235					

*Significant difference between proportions using P. Chi-square test at 0.05 level.

Table (4) represent the association between the adolescent's behavior and their socio economic status, the study results indicate that there is a non –significant association at p-value more than 0.05; Burks Behavior Rating Scale (BBRS)at p-value (0.185) .

Discussion of the Results

Table (1) show distribution of the study sample by their adolescents demographic data, this table indicates that the highest percentage (more than half) (58%); (82.6%) are females of broken and control samples respectively. This result indicates that there were females students of broken homes more than males students in the secondary schools; these findings agree with results obtained from study done by) Pauwels and Svensson, (2017. This result is due to the presence of disputes between parents or family disintegration. This generates conflicts and problems for the children, as it leads the children, especially the girls, to research and clings to any outlet that leads them to alleviate or break out of these conflicts and to prove their existence, and this can only be found through school. Especially in the Najaf community, where the available resources for girls are much less than for boys with more supervision for girls, especially in adolescence, which is characterized by aspirations for freedom and independence [(5)].

While the results revealed that more than half (51.1%); (67%) of age is 16-17 years of broken and control samples respectively; these findings agree with results obtained from study done by (Tremblay et al., 2018). This result is due to the period in which they were born. The society has suffered in many political and economic problems, in addition to the openness that the country witnessed and other factors have rocked society, especially the family. The disintegration has increased during that period [(6)].

Concerning the level of adolescent's education, the study indicates that more than half (54.7%); (54.9%) at secondary school of broken and control samples respectively; these findings agree with results obtained from study done by)Atsushiet al., 2018) [(7)]. While there are more than quarter (29.3%); (45.1%) of broken and control samples respectively in fourth and fifth class, with average level (39.6%) of broken sample, and good level (89.7%) of education with control sample; these findings agree with results obtained from study done (Amato and Sobolewsk, 2001) [(8)]. This result is due to the fact that most of the samples members are between 16-17 years old and who are usually in this stage of study. Addition the lower educational level to middle due to loss or lack of supervision by the parents, with the mental, emotional and behavioral problems faced by the teenager, as well as difficulties in the family. All of this reflects negatively on all levels of the adolescent's life, especially the academic level, with the loss or lack of interest of the educational staff in the student, making the student's level be less than good.

The highest percentage of number children in the family are (43.5%); (46.4%) of fourth to sixth of both samples respectively; these findings agree with results obtained from study done by (Cohen, 2014). This result is due to the occurrence of most cases of family disintegration when the number of its members increases, which creates burdens on the family breadwinner and consequently the family's neglect and disintegration. Therefore, the order of adolescents plays a major role in determining the method of family upbringing, especially in dealing with children [(9)].

While adolescent's age at broken family indicates that more than third (31.7%) occurred at ten to twelve years; these findings agree with results obtained from study done by) Banket al., 2001). This result is due to

the burdens of living and the increasing requirements of adolescents as they get older, with the inability of parents to manage family affairs with the problems of life facing the family in light of the unstable political, economic and security conditions of the country, with the increase in the number of family members. These factors can lead to family disintegration and incoherence[10].

Children rank in family are more than third percentage (37.1%) at second in broken sample, while (44.2%) at first in control sample; while the results revealed that the highest percentage (48.3%); (100%) is number of failure at less than one year of broken and control samples respectively; these findings agree with results obtained from study done by (Anderson et al., 2017). This result is due to the varied socio-demographic of the family who live in a poor or semi-poor family [11].

Respondents were asked whether both parents were alive (Figure 1), the findings indicate that the more than half percentage (54.7%) of no father alive; while mother alive is two-third percentage (76.7%) of broken family sample; these findings agree with results obtained from study done by (Lauren and Laura, 2008). This result is due to the Iraqi society, especially Najafi, the main breadwinner for the family is the father, and the dependency is high, as well as the large role in meeting most of the basic needs necessary for family members, especially individuals without adolescence. In the case of losing the father, the entity and cohesion of the family can permeate or weaken and also generate economic and social burdens on the rest of the family members, especially the mother or big brother [12].

Figure (2) show distribution of the study sample by their parents marital status, it indicates that the majority percentage (50.8%) of father died and the divorced is (21.5%); while lowest percentage (3.9%) is both parent died of broken family; these findings agree with results obtained from study done by(Rialaet al., 2013). This result is due to living in single parent families or stepfamilies caused by death had higher negative consequences for adolescentthan living in single parent families caused by divorce, due to fathers take on the principal caring role. In general, the results of this study give support to the weak social position of the mother as the most likely explanation for the negative effects of living in a single parent family [13].

Table (2) show association between educational level for the students related to the adolescent's behavior levels broken family in secondary schools, represent the association between the adolescent's behavior and their educational level for the students, the study results indicate that there is a significant association at p-value more than 0.05; these findings disagree with results obtained from study done by (Umar, 2019); the study results indicate that there is significant influence of broken homes on the academic adjustment of secondary school students [14].

Table (3) show association between type of family related to the adolescent's behavior levels broken family in secondary schools, represent the association between the adolescent's behavior and their type of family, the study results indicate that there is a non – significant association at p-value more than 0.05; these findings agree with results obtained from study done by (Maggie, 2017);individual's adolescent family the study results indicate that the degree of support and sense of belonging individuals felt towards their family during adolescence, as well as their parent's relationship history were associated with low. Table (4) show association between socio economic status related to the adolescent's behavior levels broken family in secondary schools, represent the association between the adolescent's behavior and their socio economic status, the study results indicate that there is a non –significant association at p-value more than 0.05; these findings agree with results obtained from study done by (Hughes et al., 2017); the study results indicate that lower levels of family cohesion are an indicator of poor family relationships and may a healthy development. This result is due to the families characterized by unsupportive and neglectful relationships and conflict constitute risky environments that may lead to worse mental and physical health across the life, operating through pathways such as stress, emotion processing, social competence, and risky health behaviors[15].

Conclusions

1. The study confirms that more than half of the study are female adolescent under broken family.
2. The study indicates that the broken family has a non-significant relationship to SESS.
3. The study indicates that most of adolescents have a behavior problems with their broken family.
4. The findings from this study lead to the conclusion that broken family have immense Impact of Adolescent's Behavior at Secondary Schools in AL-Najaf AL-Ashraf City.

Recommendations:

1. Government should review upward minimum salary from the current amount to reasonable and substantial level to better the lives of the average citizen in the country.
2. Employment opportunities should be created for the unemployed parents.
3. Should, through enacting laws and the media, to enhance and improve the quality of family life.
3. Parents should be enlightened on the need to stay together as husband and wife to raise a good family. They should persevere and tolerate each other in marriage.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the College of Nursing, University of Kufa, Iraq and all experiments were carried out in accordance with approved guidelines.

The Safety and Efficacy of Sacral Neuromodulation on Refractory Urgency Urinary and Fecal Incontinence in Iraqi Patients

Mohammed Bassil Ismail[1], Wameedh Qays Abdullhussein[2]

[1]CABMS (Urology), Urology Department, College of Medicine, University of Baghdad,
[2]CABMS (Neurosurgery), Medical City Complex, Baghdad

Abstract

Background: Urinary urgency incontinence is characterized by symptoms of involuntary loss of urine that preceded or accompanied by sudden desire to void. Fecal incontinence is defined as involuntary passage of stool through the anus. It may vary from soiling to complete evacuation. This involuntary loss of feces, flatus or urge incontinence adversely affects quality of life.

Objectives: To evaluate the efficacy and safety of sacral neuromodulation on these pathologies.

Method: Following a detailed investigation, 21 patients with either urinary incontinence, or both urinary and fecal, who did not respond to medical and behavioral treatment were offered the sacral neuromodulation therapy and followed for at least 12 months post implant regarding response and development of complication if any found.

Results: In the period from November 2015 to May 2017. The unit of neurogenic bladder and neuromodulation in surgical subspecialty hospital, medical city complex had implanted 21 Patients with urinary incontinence were using from (4-17) pads/day (mean of 10.5/day) presacral neuromodulation which were declined significantly to (0-3) pads/day (mean of 2.2/day).

From the eighteen patients who presented with fecal incontinence after the implantation of sacral neuromodulation interstim 11 permanent devices only four remained incontinent .and from the nine patients who presented with erectile dysfunction only two remained impotent.

Conclusion: The use of Sacral Neuromodulation in Iraqi patients with Urinary and Fecal Incontinence is safe and effective

Keywords: *Sacral Neuromodulation, Urgency urinary incontinence, fecal incontinence.*

Introduction

Sacral neuromodulation (SNM) is considered now a well-accepted tertiary treatment modality for patients complaining from refractory nonneurogenic bladder symptoms and nonobstructive urinary retention.(1)

Sacral neuromodulation was FDA approved for the treatment of urgency urinary incontinence since 1997.(2)

Its exact action mechanism is not fully defined, but it most likely involves the electrical modulation and reset of neuronal reflexes and voiding center through peripheral afferents and not stimulating the detrusor bladder muscle or urethral internal or external sphincter directly.(3-4)

SNM is very effective in the management of many urological diseases refractory to medical therapy, like frequency–urgency syndrome, nonobstructive urinary retention, neurogenic bladder, and others. Sacral neuromodulation has been FDA-approved as proven effective treatment modality for the management of fecal incontinence in 2011.(5)

It modulates the spinal cord reflexes that affect the bladder, urethra, anal sphincter and pelvic floor muscle.(6)

Urgency urinary incontinence (UUI) is defined as involuntary loss of urine that precede or accompanied by sudden desire to void. Urgency incontinence is considered refractory when shows no response to behavioral therapies and at least two medications.(7) The prevalence of urgency urinary incontinence increases with age.(8)

Fecal incontinence is a humiliating life-altering condition that affects nearly 2% of population.(10)

Patient and Method

A prospective cohort study was conducted in a tertiary referral specialized neuromodulation unit to assess the efficacy of SNM in patients with refractory urinary and fecal incontinence. All patients between 16 and 61 years of age, who were referred to surgical subspecialty hospital, medical city complex complaining from Urinaryand Fecal Incontinence refractory to conservative treatment, were eligible to be included in this study. Informed consent was obtained from all patients and first-degree relatives.

Full detailed history and prior treatments were collected from them, full physical examination was done 3 days voiding diary.

Further diagnostic tests included urinalysis, abdomino-pelvic ultrasound, renal function test, full urodynamics, lumbosacral MRI, flexible cystoscopy was done to all patients.

All those patients should have urinary incontinence alone or associated with fecal incontinence According to guidelines both American and European offered conservative treatment for at least 8-12 weeks if failed so, Refractory incontinence was considered with persistence of symptoms despite at least one supervised behavioral or medical therapy or both for at least 8-12 weeks.

Exclusion Criteria:

1. Patients with urinary incontinence due to intrinsic sphincteric deficiency.
2. urinary incontinence due to anatomical abnormality like ectopic ureter of vesicovaginal fistulae
3. Patient age less than 16 years.
4. Patients who had less than 50% improvement in their symptoms during temporary stimulation phase.
5. Patients with pure fecal incontinence (we do not have the facility to exclude abnormality in the anal sphincter)

Those patients were offered sacral neuromodulation in two stage surgery in the first-stage tined lead placement in S3 foramen under fluoroscopic examination. Both motor and sensory responses were assessed for all electrodes independently if there is good response the lead will place and connected to external temporary device. During the two weeks of testing phase, patients will be followed by 3 days voiding diary and full bladder pelvic ultrasound programs will be changed by the surgeon to optimize good results. Patients with more than 50% response were considered as responders and permanent device was implanted for them.

Scheduled visits postimplant from the patients to the outpatient after two weeks and the programmed, every 3 months for at least 4 or 5 times for at least one year and inquire about any undesirable side effects.

Results

In the period from November 2015 to May 2017 the unit of neurogenic bladder and neuromodulation in surgical subspecialty hospital, medical city complex had implanted 21 permanent interstim II devices in 21 patients with age ranging from 16 to 61 (table 1) year old complaining from urgency urinary incontinence 18 patients had also associated fecal incontinence, and nine of them had erectile dysfunction also. all the patients were followed for at least one-year post implantation.

Table 1: Descriptive characteristics of studied sample

		No.	%
Age groups	< 40 year	16	76.2%
	=>40 year	5	23.8%
Gender	Male	12	57.1%
	Female	9	42.9%
Diagnosis	Urgency incontinence	21	100%

Patients with urinary incontinence were using from (4-17) pads/day (mean of 10.5/day) presacral neuromodulation which were declined significantly to (0-3) pads/day (mean of 2.2/day). (Table 2, table 3).

Table 2: Mean number of pads pre and post SNS

Paired Samples Statistics				p-value
No. of pads/day	**Mean**	**Std. Deviation**	**Mean difference**	
Pre	10.5	3.5	8.3	0.001
Post	2.2	1.6		

Table 3: Number of pre and post pads according to number of patients

No. of patients	No. of pads/day pre-sns	No. of pads/day post-sns											
		0		1		2		3		4		5	
		No.	%	No.	%	No.	%	No.	%	No.	%	No.	%

4	10	0	0.0%	0	0.0%	3	75.0%	1	25.0%	0	0.0%	0	0.0%
3	11	0	0.0%	0	0.0%	2	66.7%	0	0.0%	1	33.3%	0	0.0%
2	12	0	0.0%	0	0.0%	0	0.0%	1	50.0%	0	0.0%	1	50.0%
2	13	1	50.0%	0	0.0%	1	50.0%	0	0.0%	0	0.0%	0	0.0%
1	14	0	0.0%	0	0.0%	0	0.0%	0	0.0%	1	100.0%	0	0.0%
2	15	0	0.0%	0	0.0%	0	0.0%	1	50.0%	1	50.0%	0	0.0%
1	17	0	0.0%	0	0.0%	0	0.0%	0	0.0%	0	0.0%	1	100.0%

From the eighteen patients who presented with fecal incontinence after the implantation of sacral neuromodulation interstim 11 permanent devices only four remained incontinent .and from the nine patients who presented with erectile dysfunction only two remained impotent (nearly all those patients didn't even mention this complaint primarily may be due to that their incomitance where their major complaint or maybe they were embarrassed). (Table 5).

From the twenty-one patients treated by sacral neuromodulatin two patients had simple pain at the site of implantation some time radiating to their legs treated by reprograming of the device and simple analgesia. One patient had device infection and another had device malfunction due to direct trauma to the device treated by removal of the device and reimplantation of another device in the contralateral site. (table 4)

Table 4: Frequency of complications post SNS

	No.	%
Nill	17	81.0
Simple pain	2	9.5
Device infection	1	4.8
Device malfunction	1	4.8
Total	**21**	**100.0**

Table 5: Status of incontinent and ED pre and post SNS N=21

		No.	%
Bowel status			
Incontinent	Pre-sns	18	85.7%
	post-sns	4	19.0%
Potency status			
Ed	pre-sns	9	64.3%
	Post-sns	2	14.3%

Discussion

Sacral neuromodulation (SNM) is proved to a valuable addition to urology as an option for the treatment of patients with refractory urgency frequency syndrome whether dry or wet, and urinary retention or non-obstructive unresponsive to behavioral and medical treatment.(11)

Sacral neuromodulation is an attractive treatment modality because of its minimally-invasive approach. (12)

Although sacral neuromodulation is very effective in patients with sphincteric defect, its action is thought to be extrasphincteric. It has been suggested to act centrally through spinal afferents.(13)

The impact of SNM on anorectal physiology was variable. However, there appeared to be a trend towards improved anal pressures (as evidenced by increased resting and maximum squeeze pressures) and rectal sensitivity (as evidenced by a decrease in sensory threshold volumes).(14)

In addition, it has been suggested that SNM creates a change in the colonic activity a 'physiological brake' so prevents the delivery of stool to the anorectal unit that is functionally suboptimal and thus reduces fecal incontinence.(15)

SNM may modulate the higher voiding center reflex pathways by resting the balance between the excitatory and the inhibitory fibers of the bladder. (16)

In our study we offered sacral neuromodulation via implantation of interstim II devices to twenty one patients with refractory urgency urinary incontinence, eighteen one of them complaining from fecal incontinence, nine of them complaining from erectile dysfunction.

After at least one year follow up post sacral neuromodulation for the patients there was a significant decrease in the number of pads used by the patients (mean preSNM10.5, meanpostSNM 2.2). Only four patients from the eighteen complaining from fecal incontinence remained incontinent .seven from the nine patients with erectile dysfunction became potent again.

No serious complication faced by the patients during or following SNM for at least one year . 17 patient had nil complication.

Several studies have demonstrated the efficacy of SNM on both urinary and fecal incontinence for the short and long term which has results approximates to our own.

Van Kerrebroeck et al showed that there was a decrease in the episodes of urgency urinary incontinence from 9.6 preSNM to 4.7 at 1-year postSNM. The number of pads/daypostSNM decreased to 1.8 from 5 pads/day preSNM at 5-year follow-up. (17)

Maeda et al showed 42.6% favorable outcome of sacral neuromodulation in patients with fecal incontinence after 60 months of follow up.(18)

In conclusion according to above results we believe that Sacral Neuromodulation is safe and effective method of treatment in refractory urgency urinary and fecal incontinence.

Glycodeline-A, sFlt-1, PlGF Combined as Predictor Markers of First Trimester Pregnancy Loss in Iraqi Women

Mohammed H. Dawood[1], Halla G. Mahmood[2], Afraa M. Nedawi[3]

[1]Clinical Biochemistry, Ministry of Health, Baghdad, Iraq, [2]Clinical Biochemisrty, Biochemistry school, Scientific School, University of Baghdad, Baghdad, Iraq, [3]Clinical Pathology, Department of Pathology, College of Medicine, University of Baghdad, Baghdad, Iraq

Abstract

Objective: evaluate the serum level of Glycodeline-A, sFlt-1, PlGF combined with βhCGas predictor markers of first trimester pregnancy loss in Iraqi women.

Method: A case-contol study, carried out from April 2019 to March 2020 and included 85 women, 40 of them as patients which have abortion at the first trimester and 45 of them as healthy control which haven, t any complication at the same time of gestation, investigations included serum measurements of βhCG, Glycodeline-A, sFlt-1, PlGF By Method ELISA.

Results: Serum NiveausβhCG, sFlt-1 Was major higher in healthy controls than in patients, while serum level of Glycodeline-A, PlGF was significantly lower in healthy control than in patients, and there is no significant correlation among each of age with other parameters, and there is no significant correlation among each of gest.age with Glycodeline-A and sFlt-1, while there is significant correlation among each of ges.age with βhCG and PlGF $P<0.05$.

Conclusion: The present study suggested the significant role of Glycodeline-A, sFlt-1, PlGF in pathogenesis of first trimester pregnancy loss and some of them was related to βhCGin this period and the age of patients wasn, t effect on all of these parameters.

Keywords: *βhCG, Glycodeline-A, sFlt-1, PlGF.*

Introduction

Pregnancy defined as the condition of carrying fetus at the pregnant woman, and can be confirmed by positive urine or blood test with ultrasound that is detection of fetal heartbeat, an X-ray may be using, this condition stay about 9 months begining from the first day of the (LMP) of the woman, this state is divided ordinarily In three parts, each part DreiMonate period[1], More important basic cell differentiation Occurrence of fetal during the first three months of pregnancy, so any complication During this stage the embryo is leading to result represent Grave or pregnancy complications, the consistence of blood flow of fetal placental and uteroplacental is the important side of processes of pregnancy and fetal consistence[2], successful morphogenesis of uterine placental vascular with successful Morphogenicity of fetus blood circulation are the main factor In these Two Phases systems existing represent these processes of morphogenesis vascular: vasculogenesis: firstly development formation of the blood flow from the activated cells of mesodermal Angiogenesis and : novel vessels Through Blood is formed from present vascular form, which is represent the consistence and development of the system of vascular fetus and placenta through pregnancy. There is no prevent work to protect the pregnant from the miscarriage especially when this situation is occurring whith unknown reason which is undetect, in other site there are many causes that increase the danger of miscarriage, if the pregnant is having difficult maintaining of her carry[3], the specialist may evaluate some known reasons of miscarriage and remove it through carry, supplemet of hormones and nutrients can help to developing embryo, this growing of embryo happened mostly in the first three months of carry, in

most cases miscarriages due to the defect of normally fetus growing[4], the various symptoms of miscarriage depend on the time of carry age, it happens rapidly even before she know pregnant, these signs include bleeding vagina[5], tissue drainage,cramping or severe lower pain,back pain mild to heavy, Growth factors play a vital role in the development of vessels; they function as cell mitogens; as attractants in the creation of vascular architectonics; and most notably, as morphogens; the major regulators of angiogenesis are part of the VEGF[6] complex. In addition to direct angiogenesis activators, there is a wide number of causes, including matrix metalloproteinases (MMPs) and their tissue inhibitors (TIMPs), whose effect on angiogenesis is non-specific. production of antiangiogenic Factors are an important part of natural angiogenesis, leading to molecular communication. vascularization[7], The manufacture of inhibitors acts as a deterrent to unnecessary invasion of trophoblasts, as well as a deterrent to the further growth of the vascular bed and vascularization of pathologically affected tissue locations, angiogenic factors expressed primarily in endothelium and placenta during pregnancy, including receptors VEGFR1 (sFlt1), VEGFR2 (Flk1, KDR) and VEGFR3 (Flt4)[8], soluble variants of these receptors are able to bind growth factors in circulation, halting or blocking angiogenesis, Humoral factors implicated in vascular development processes are more available for study in maternal circulation, and alteration in their content in mother's blood indicates shifts in the quality of these factors in the fetal blood circulation and tissues9. In this regard, a detailed analysis of variables and their ratios correlated with angiogenesis is critical for understanding and predicting vascular morphogenesis disorders during pregnancy[10],Apparently Soluble tyrosine kinase-1-like fms (sFlt-1) interferes with the events that Inhibiting central angiogenesis and/or blocking invasion of trophoblast. Improved development of Fms-like receptor of tyrosine kinase -1 (sFlt-1) soluble antiangiogenic agent The placenta contributes to the obstetric Physiotherapy . sFlt-1 Is expressed at very high trophoblast rates, and its development in hypoxic conditions is greatly increased role sFlt-1 in pregnancy failures is the focus of ongoing investigation[11]. SFlt-1 in maternal circulation therefore decreased was recently Proposed as a probable distinguishing feature the peril of defeat of pregnancy,PlGF is the angiogenic component most commonly controlled in an uncomplicated first trimesterdeciduas, Discovering the involvement of angiogenic factors (sFlt-1/PlGF) in the underlying placental disorder pathophysiology, taking into consideration the biomarkers correlated with angiogenesis are related to a High placental insufficiency disorder, these markers are Relevant to early detection and forecasting assessment[12], Glycodelin-A (GdA) is an abundant first- trimester glycoprotein deciduas[13] . It participates in fetomaternal defense and early placental growth of different immune cells via its regulatory activities, glycodelin-A is a glycoprotein Consistent with its average expression between 6 and 12 weeks of development in the decidua,Abnormal endometrial rates of glycodelin-A, uterine flushes, and/or maternal serum associate with unexplained miscarriage, early termination of child, and recurrence miscarriage[14].

Aim of the study: To study its position Glycodeline-A, sFlt-1, PlGF combined as predictor markers of first trimester pregnancy loss in Iraqi women.

Method

Study Design: The present project was conducted at the branch of Biochemistry, Medicine College, Baghdad University, at Hospital of Baghdad Teaching through the time from April 19 to March 2020, it included 85 pregnant woman identified the first day of LMP who are confirmed positive pregnancy test in blood, and established to have had pregnancy by Consultant Gynaecologist and matching age 21–35 year and same time 8–12 week of pregnancy and encountered during their attendance the Gynaecology consultation clinic at Baghdad Teaching hospital, encountered these women until the end of week 12 of pregnancy, 40 of them who have pregnancy loss at the prognosis period are patients and the other 45 healty control who completed the same period without problems, a written consent was applied by each patient and an ethical approval had been suitable the researcg based of the Medicine College, Baghdad University and the link with Ministry of Health and enviroment.

Data Setting: Eight to ten milliliters (mls) of blood from subjects are draw out and transferred into plain tube, allows for half hour to sure that is clotting, after this, the specimen must be centrifuged to separated the needed serum at 2500 rpm for limited time roughly ten minuted and stored at freezing degree about – 20 Co up to beginning of the assay the project biochemical markers : Beta HCG, Glycodeline-A, sFlt-1, PlGF By ELISA method .

Inference by Statistics: Inference by statistics is a method that analysis of details by using SPSS, this

information were putting as simple measures of variants (mean, standard deviation and others), qualitative detailes which are significant statistically were using student-t-test for compare between two independent means or ANOVA test for compare between different qualitative detailes on, the statistical significance is equal or less than 0.05, the coefficient of correlation value r : is a kind of coefficient correlation clarify the connection between two different factors that are calculated on the same period, r may be positive as direct correlation or negative as inverse correlation.

Results

Explain by table scales of various markers and their correlations according to the study assessment .

Discussion

Serum level of βh in healthy control group (mean ± SD 2309.940 ±3007.116) in patients which have abortion (1024.774 ±4 59.394) which show significant correlation : P value 0.05, that mean the level of this marker in patients was lower than in healthy control, The present study shows that the serum level of glycodelin-A in healthy control group (mean ± SD 193.741 ± 200.566), in patients which have abortion (70.944 ± 56.873) which show significant correlation : P value 0.01, that mean the level of this marker in patients was lower than in healthy control, The present study shows that the serum level of sFlt-1 in healthy control group (mean ± SD 22.269 ± 19.163), in patients which have abortion (118.215 ± 76.424) which show significant correlation : P value 0.05, that mean the level of this marker in patients was higher than in healthy

control, The present study shows that the serum level of PlGF in healthy control group (mean ± SD 340.294 ± 387.017), in patients which have abortion (141.453 ± 284.108) which show significant correlation : P value 0.05, that mean the level of this marker in patients was lower than in healthy control, most of previous projects have found that the chromosomal agents are effective factor in carry loss[15], old studies have demonstrated that the normal carry depends on normal immune system which is consist of immune defence, immune response, cytokines[16], the immune effect is important factor in first carry failed, the immune units that establish at the mediater of placenta and the uterus were stay overlap layer of arrangment by immunity system of mother, this process may help of placental growth but some times reduce the placental aggress the embryo, in the time of implantation natural killer units go to the uterus and help the stimulation secrete of cytokines that inhibit the trophoblast aggress[17].

Conclusion

Scales of all markers according to the result which obtained from the assessment of them are clarify the relation between patients which have abortion in the first trimester and healty control, these results suggest for βhCG: level of this marker in Patients were beyond safe regulation,and for Glycodelin-A: level of this marker in Patients fall beyond safe monitoring,and for sFlt-1: level of this marker in has been careful higher as in healthy check, and for PlGF: level of this marker in patients were beyond safe regulation .

Ethical Approval: Describe written consent was applied by each patient and an ethical approval had been suitable the researcg based of the Biochemistry Department,Medicine College, Baghdad University and the link with Iraqi Ministry of Health .

The Effect of Using Panicum Mombasa Hay and Millet Hay in the diet on the Production Performance of Awassi Lambs

Mohammed H . Fannos[1], Husam H. Nafea[1], Ahmed A. Al-Ani[2]

[1]Student, [2]Prof., College of Agriculture, University of Anbar, Iraq, [2]Research Scholar, Office of Agricultural Researches, Ministry of Agriculture, Iraq

Abstract

The current study was conducted at Al- Dawar Research Station (30 km to the northeast of Ramadi district center in Anbar Governorate)/Ministry of Agriculture/Agricultural Research Organization/Department of Animal Resource Researches, and for the period from November 1, 2019, to February 1, 2020. This research aims to study the feeding role on the *Panicum maximum* Mombasa hay and Millet hay compared to the alfalfa hay and the mixing between them on the production traits of Awassi lambs. In this experiment, 20 heads of Awassi sheep were used, their ages ranged from 5 to 6 months, and their average weight was 37 ± 0.75 kg. The animals were distributed randomly into five treatments, each treatment containing 3 females and one male; all animals were fed (group feeding/treatment) during the experiment time on the same diet of concentrated forage provided at a percentage of 2% of live body weight/treatment/day. As for the rough forage, it was also provided daily/treatment, but freely, and the next morning the remainder of the concentrated and rough forage was weighed/group. The average total weight gain, the average daily weight gain, the average daily consumption, and the feed conversion efficiency were calculated, and it was observed that there were no significant differences between the treatments in the average live body weight, the total and daily weight gain, the amount of total feed intake (concentrated and rough) and the feed conversion efficiency. It can be concluded from this that the use of *Panicum maximum* Mombasa hay and Millet hay did not negatively affect the product performance of the Awassi lambs.

Keywords: *Panicum Mombasa Hay, Millet Hay, Production Performance, Awassi Lambs.*

Introduction

Iraqi sheep are characterized by low production due to malnutrition, weak soil programs, improvement and poor management, and among the most important reasons that lead to low livestock productivity that is considered, as one of the main problems that farmers face to increase their livestock production is the lack of available forage. One of the important ways to increase the availability of forage in Iraq is to introduce improved forage crop varieties and plant them in the appropriate areas, as there are many types of forage that have been newly introduced, including Panicum (*Guinea grass*). It is a plant of the Poaceae family, where its scientific name is *panicum maximum* and the English name is Guinea grass[(1)], which is considered a perennial herb[(2,3)]. However, its cultivation succeeds in tropical and subtropical regions of the world, and it has a tremendous system of roots, which makes its resistance to drought high. In addition to that, it tolerates high temperatures (37-40°C); while the height of Panicum may reach three meters and is characterized by good palatability and a high yield of good quality leaves[(4,5,6)]. Furthermore, its production period is up to ten years, which its productivity is higher than that of alfalfa, Panicum tolerates high salinity of water and soil[(7)]. Other ways to increase the availability of feed include the use of improved varieties, which are characterized by high production of forage and rapid growth, and their high ability to regrow them, as they have become the focus of researchers' attention to

cultivate and improve them[8]. Among these crops is also the millet plant (*Pennesetum glaucum* L.), where millet is one of the seven most important crops in the world and the second most important crop grown primarily for a dual-purpose after maize. Besides, it is a major crop in semi-arid regions of India and Africa[9] and is from the summer crop, which is characterized by abundant growth and many branches, with its smooth, erect stem that carries a large number of leaves that have the ability to regrowth. As it is possible to obtain 3-4 cuts during the growing season, in addition to that the productivity of green forage for millet is superior to many varieties of sorghum[10],[11] mentioned that the millet plant could play an important role as a source of forage for ruminants due to its high tolerance to droughts, its short growth cycle that ranges from 60 to 90 days, and its effective ability to regrowth. Finally, the current study aimed to identify the role of feeding on the Panicum Mombasa hay and millet hay, compared to the alfalfa hay and mixing them on the productive performance of the Awassi lambs.

Materials and Method

Animal Feeding: All the experimental animals underwent a preparatory stage for a week before the experiment starts, as all of them were fed (group feeding/group) on concentrated forage, as shown in Tables 1 and 2 at a percentage of 2% of the total live body weight/group, as it is provided at eight in the morning. The rough forage was provided freely as shown in Table 2, where the animals of the first treatment (T_1) were fed on alfalfa hay, the second treatment (T_2) on Panicum hay, and the third treatment (T_3) on millet hay. Also, the fourth treatment (T_4) on 50% millet hay and 50% alfalfa hay, and the fifth treatment (T_5) on 50% Panicum hay and 50% alfalfa hay. The quantity of both concentrated and rough forage consumed daily for each treatment was calculated by weighing the amount provided and subtracting the remaining during the experiment time. While drinking water and mineral salt block were always available for all animals during the experiment. The animals were weighed weekly with an electronic balance for small ruminants to calculate the weight gain/animal/week, in addition to adjusting the concentrated forage quantities provided to each group in light of the total live body weight/group.

Total protein	14.97	15.25	16.68	13.14

Results and Discussion

Average Weekly Weight Gain: Table [3] showed the effect of using Panicum and millet hay on average body weights during the experiment time, as there was no significant difference between the treatments in all periods of the experiment.

Table [3]: The effect of using Panicum hay and millet hay in the diet on average live body weight (Mean ± standard error)

Weeks	Treatments					Sig.
	T_1	T_2	T_3	T_4	T_5	
1 week	36.60 ±2.10	39.10 ± 2.00	39.26±3.18	38.13±1.77	38.66 ±1.04	NS
3 weeks	38.66 ±2.77	41.20 ±1.85	41.66 ±3.18	40.53 ±2.06	41.00 ± 1.70	NS
5 weeks	40.93 ±3.34	43.06 ±1.79	42.73 ±3.12	41.60 ±2.41	42.60 ± 2.10	NS
7 weeks	41.26 ±1.61	43.53 ±1.47	44.0 ±3.63	43.56 ±2.18	43.93 ± 2.00	NS
9 weeks	42.33 ±2.40	45.86 ±0.86	47.06 ±3.69	45.66 ±2.64	45.40 ± 2.38	NS

13 weeks	48.40 ±3.71	50.26 ±0.98	51.53±4.09	50.93 ±2.97	51.46 ± 3.13	NS

Note: NS means that there are no significant differences between the treatments.

Except, it was observed from the results that the treatment (T_2) and (T_3) are arithmetically superior over the rest of treatments in the first week, and in the fifth week, the results showed an arithmetic increase in body weight in the treatment (T_2) over the other treatments. In the other weeks, it is evident from the same Table that there was an arithmetic increase in the average body weight in the treatment (T_3) over the other treatments. The results of this study are agreed with the (12) findings that they did not notice a significant difference between the treatments in the study, which included feeding goats on Panicum hay, green Panicum, Panicum hay and Panicum silage in average body weight. Besides, (13) did not notice a significant difference between the treatment which are fed Panicum and other treatments that are fed different types of forages. Whereas, the results of the study did not agree with (14) when feeding Panicum to African rams with the addition of leguminous grains, as the treatments of adding legume supplements are significantly superior ($P\leq 0.05$) in body weight over the treatment of Panicum only. Finally, (15) noted significant differences ($P\leq 0.05$) in the average body weight of goats fed on Panicum while providing cobalt in different proportions orally.

Total Weight Gain: The results of Table 4 showed the effect of using Panicum and millet hay in the diet on the average total weight gain during the experiment time. It was observed from the results that there were no significant differences between the treatments, but there is an arithmetic superiority in the treatment (T_4) and the treatment (T_5) over the other treatments. The results of the study agreed with the (16) findings in their experiment on goats, that there was no significant difference between the treatment fed on Panicum and the treatment fed on Panicum with an addition of 15% of the Moringa leaves. The results did not agree with (13) finding, in which they were observed significant differences ($P\leq 0.05$) between the treatments in the average total weight gain. As well as, (14) showed the presence of a significant difference ($P\leq 0.05$) between the treatment that fed only Panicum and the treatment that fed on Panicum with the addition of legume supplements, the treatments that were added to the legume supplements were superior.

Daily Weight Gain: It is evident from the results of Table [4] that there were no significant differences between animals in the average daily weight gain between treatments and for all periods, and the Table observed the arithmetic superiority in the treatments T_4 and T_5 over the other treatments. These results are consistent with the[17] findings that showed there were no significant differences between calves fed on Panicum and calves fed on different grass, and[12] did not observe a significant difference between the treatments of four forms of Panicum (hay, green, silage, and hay) that were fed to sheep. Moreover, the results of this study did not agree with what [11] findings when feeding rams on the millet silage with the addition of different percentages of urea, and significant differences ($P\leq 0.05$) were observed between the treatments, as the addition treatments were superior in the daily weight gain. Furthermore, [18] showed in a study on African goats, there was a significant difference ($P\leq 0.05$) between the treatments, where the treatments fed on Panicum by adding 10 and 15% of the Moringa leaves were significantly superior ($P\leq 0.05$) to the treatment fed on Panicum only.

Total feed intake: It is evident from the results of Table [4] that there were no significant differences between the treatments in the amount of total feed intake. However, it was observed from the Table results that there was an arithmetic increase in the amount of feed intake in the treatments T_1, T_2, T_5, the results are consistent with[17,18]. These results differed with[14] findings when they fed rams on Panicum and Panicum with the addition of legume supplements, as they found a significant difference between the treatments in the amount of feed intake.[19] observed the presence of a significant increase in the amount of feed intake between the treatment of rams that fed on Panicum only and treatments that were fed Panicum with the addition of different proportions of cotton seeds and Moringa leaves.

Feed conversion efficiency: It is evident from the results of Table [4] that there was no significant difference between the treatments in the feed conversion efficiency, where the treatment T_2 achieved a mathematical improvement compared to other treatments. The study results agreed with (13), and with (12) that observed no significant differences in the feed conversion efficiency when feeding goats on Panicum compared to other treatments. The study results differed with the (14) findings, that showed a significant difference ($P \leq 0.05$) in the feed conversion efficiency of male African sheep, where the treatment that fed Panicum with the addition a variety of legume supplements exceeded over the treatment fed on Panicum only.[11] study showed that there was a significant improvement ($P \leq 0.05$) in the treatment of sheep fed on the millet silage with an addition of 20% of urea in the feed conversion efficiency over the treatment fed on the millet silage without any addition.

Table [4] The effect of using Panicum hay and millet hay in the diet on the total and daily weight gain, feed consumption and feed conversion efficiency (mean ± standard error)

Treatments	Studied traits			
	Total weight gain (kg)	Daily weight gain (g)	Amount of feed intake (hay + concentrate) (kg)	Food conversion efficiency
T_1	11.80 ± 1.61	131.11 ±17.96	476.64 ± 12.36	8.25 ± 0.52
T_2	11.16 ± 1.64	124.07 ±18.32	471.40 ± 10.55	7.90 ± 0.39
T_3	12.26 ± 0.96	136.29 ± 10.75	462.80 ± 10.26	8.83 ± 0.64
T_4	12.80 ± 1.24	142.22 ± 13.87	456.76 ± 9.46	9.34 ± 0.64
T_5	12.80 ± 2.10	142.22 ± 23.23	475.75 ± 12.52	8.96 ± 0.51
Significance level	NS	NS	NS	NS

Note: N.S means no significant differences between the treatments

Conclusion

The study results observed the absence of significant differences between the five treatments in each of the average weekly body weight, total and daily weight gain, the total amount of forage (concentrated and roughly) intake, and the feed conversion efficiency.

Effect of Combined Antibiotics and Biofilm Formation in Some Bacterial Pathogens from Otitis Media among Children in Baghdad, Iraq

Mohammed Khudhair Alwan[1], Kais Kassim Ghaima[2], Zainab Shaban Khalaf[1]

[1]Ministry of Health, Baghdad, Iraq, [2]Institute of Genetic Engineering and Biotechnology for Postgraduate Studies, University of Baghdad, Baghdad, Iraq

Abstract

Otitis media bacterial infections during childhood may contribute to the development of repeated nasopharyngeal infections and it is complicated of recurrent or chronic middle ear diseases, especially with multidrug resistant strains.

The results of antibiotic synergism for the most prevalent three bacterial species, isolated from otitis media infections in children, and had the highest antibiotic resistance was revealed that combinations ceftazidime-amikacin and ceftazidime- ciprofloxacin displayed synergistic activity fractional inhibitory concentration (FIC ≤ 0.5) against the most of tested isolates; *Pseudomonas aeruginosa*, *Porteus mirabilis*, and *Klebsiella pneumonia*. In the biofilm test all tested isolates were showed biofilm production by tissue culture plate method (TCP), in the present study, the strong biofilm production was most prevalent in *Pseudomonas aeruginosa* (100%) followed by *S. aureus* (71.4%). Biofilm formation increases the activity of antibiotics in children otitis media infections and using antibiotics combinations may be essential for optimum management of OM patients.

Keywords: *Otitis media, Biofilm, Antibiotics, synergistic activity.*

Introduction

Otitis media (OM) is an inflammatory disease of the middle ear, with different medical conditions and symptoms. It is caused as a result of a blockage to the Eustachian tube. In contrast with adults, the Eustachian tube is shorter and more horizontal in children and also it is consists of more flaccid cartilage, which can impair its opening, therefore otitis media is more common in children [(1)]. Recurrent Acute otitis media (RAOM) causes pain and discomfort in children, also it was noted that 20–30% of infants suffer from RAOM and approximately 70% of infants experience at least one otitis episode by the age of 2 years [(2)]. Multiple otopathogens can colonize the middle ear and nasopharyngeal. The bacterial attachment and colonization, biofilm formation, and invasion of the middle ear are enhanced by the viral infections of the nasopharynx [(3)]. The main pathogenic bacteria which contribute with the middle ear infections are *Haemophilus influenzae, Streptococcus pneumoniae*, *Streptococcus pyogenes*, and *Moraxella catarrhalis*) and considered as the main risk for OM and RAOM [(4,5)]. Several studies indicated to other species whic isolated from the middle ear fluid of children as causative agents of chronic suppurative otitis media(CSOM) such as *Pseudomonas aeruginosa, Staphylococcus aureus*, *Staphylococcus epidermidis*, *Klebsiella spp* and *Escherichia coli* [(6,7)]. Most of the bacterial pathogens can form biofilm as the main step for colonization and this biofilm provide some bacteria more effective resistance and tolerance to antibiotics according to the

complicated structure of bacterial biofilm[8]. In Iraq, there is little attention about the study of the role of bacteria species in Otitis media occurrence and their capacity to the formation of biofilm and its relation to increasing antibiotic resistance. Therefore the aims of the study are: Isolation and identification of some species of bacteria, which infect the Iraqi children with otitis media infection by using conventional and molecular method. Investigate the antibiotic resistance of these isolates and study their ability to form the biofilm as a virulence factor. Also, conducting the antibiotics synergism to detection the lowest concentrations of the combination of antibiotics to avoid resistance of bacteria.

Materials and Method

The samples of the study: The collection of study samples has taken place at the period between November 2018 and completed at end of April 2019, it has included 138 clinical specimens as ear discharge samples, collected from inpatients and outpatients with otitis media infections that admitted in four hospitals in Baghdad**,** from both gender with age ranging from 6 months to 15 years**.**

Isolation and identification of bacteria: The bacterial which selected for this study were identified by biochemical tests and Vitek2 system, these isolates include 28 of pathogenic bacterial isolates distributed as 7 from 4 species (*Pseudomonas aeruginosa, Proteus mirabilis, Klebsiella pneumoniae* and *Staphyllococcus aureus*) for Quantification of biofilm formation. From the same group of bacteria, 18 multidrug resistant isolates of three bacteria species (*Pseudomonas aeruginosa, Proteus mirabilis,* and *Klebsiella pneumoniae*) were selected for evaluation the antibiotics combination

Antibiotics Synergy Test by Using Checkerboard Method: Checkerboard is method to evaluate interactions between antibiotics with serial concentrations as synergism, additive, indifferent, or antagonism [9].

Amikacin, Ciprofloxacin and Ceftazidime, each antibiotic is prepared and MICs are calculated for each antibiotic by microdilution method by using resazurin dye as described by Elshikh *et al*. (2016)[10].

The checkerboard method uses for study Synergism between Ceftazidime – Ciprofloxacin and Ceftazidime – Amikacin. The test done for most prevalent three bacterial species with the highest antibiotic resistance, which detected in otitis media cases. The concentrations were from (1 µL -64 µL) for Ceftrazidime, (0.5 µL-256 µL) for Amikacin and Ciprofloxacin. Dilution chequerboard technique was conducted to evaluate the effect of antibiotic combinations. Fractional inhibitory concentration (FIC) indices for each agent is calculated by dividing the MIC of the antibiotics when used in combination by that of the drug alone. The FIC index is the sum of the FICs of each of two antibiotics when examined in combination[11].

A minimum FIC index of ≤0.5 indicates synergy, while, if the minimum FIC index is >0.5 and ≤ 1, the effect of the combination was classified as additive. If the minimum FIC index is >1 and ≤2, the effect of the combination was classified as indifferent, and antagonistic if >2[9].

Microtitre plate assay for biofilm quantification: Biofilm was formed on 96 well flat bottom polystyrene microtitre plates as described by Kırmusaoglu (2019)[12]. Briefly, A 10 µl of cell suspension having 0.5 O.D600 nm was inoculated in 190 µl Tryptic soy broth medium in each well. Tow hundred µl of sterile distilled water was added in peripheral wells to reduce the water loss. Then microtitre plate was incubated at 37 ºC for 18 h. After aspiration of planktonic cells, biofilms were fixed with 99% methanol. Plates are washed twice with phosphate buffer saline or sterile saline water and air dried. Then, 200 µl of crystal violet solution (0.2%) was added to all wells and the excess crystal violet was removed after 5 min, and plates were washed twice and air dried. The cell bound crystal violet was dissolved in 33% acetic acid. Biofilm formation was measured in terms of O.D 570 nm using micro plate reader. Cut off value (ODc) was calculated, which can provide categorization of isolates as biofilm producer or not.

Statistical Analysis: The Statistical Analysis System, SAS (2012) [13] program used in this study. According to Chi-square test uses for significant comparing between percentages. Least significant difference (LSD) test was used to significant compare between means (0.05 and 0.01 probability) in this study

Results and Discussion

The checkerboard method uses for studying Synergism between Ceftazidime- Ciprofloxacin and Ceftazidime – Amikacin. The test is done for most prevalent three bacterial species with the highest antibiotic resistance, which detected in otitis media infections. The concentrations are from (1 - 64 µg/ml) for Ceftrazidime,

(0.5 - 256 µg/ml) for Amikacin and Ciprofloxacin. The results of MICs of three antimicrobial agents and FICs of 2 combinations against 18 isolates of three bacteria species (*Pseudomonas aeruginosa, Proteus mirabilis,* and *Klebsiella pneumoniae*) are showed in Table (1).

Table (1). MIC of antibiotic combinations and synergy test results.

Isolates	Antibiotics combination	MIC of first antibiotic alone (µg/ml)	MIC of first antibiotic in combination (µg/ml)	MIC of second antibiotic alone (µg/ml)	MIC of second antibiotic in combination (µg/ml)	FIC	Result
A1	AK-CAZ	64	16	64	8	0.375	Synergy
A1	CIP-CAZ	4	4	64	16	1.25	Indifferent

FIC: Fractional Inhibitory Concentration; AK: Amikacin; CAZ: Ceftazidime; CIP: Ciprofloxacin; A= *Pseudomonas aeruginosa,* P = *Proteus mirabilis,* K= *Klebsiella pneumoniae.*

Results revealed combinations ceftazidime-amikacin and ceftazidime- ciprofloxacin displayed synergistic activity (FIC $\leq$ 0.5) against the most of tested isolates except tow isolates *P. aeruginosa* A 1 and *P. mirabilis* P20, which showed indifferent with the ceftazidime-ciprofloxacin combination.

In the current study, none of the antimicrobial combinations tested demonstrated antagonism against any of the isolates tested. Out of 18 isolates, 11 exhibited synergistic activities, while the additive activity showed in 5 isolates, as the result of *K. pneumoniae* K4 (Figure 1).

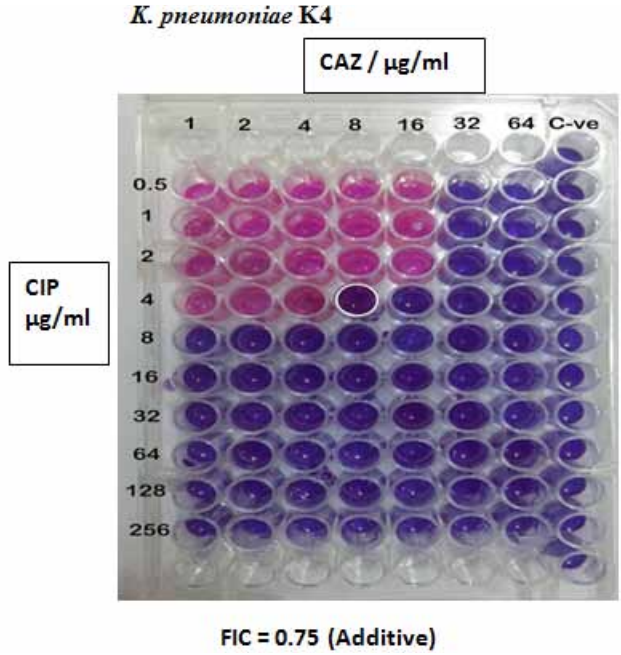

Figure (1). FIC of antibiotics combination ceftazidime-amikacin against *K. pneumoniae* K4.

The four isolates *P. aeruginosa* A1, A27, *P. mirabilis* P1, and *K. pneumoniae* K14 displayed the highest affected by the 2 combinations especially with ceftazidime-amikacin (FIC = 0.375) (Table 1).

Antibiotic combinations to the treatment the resistant infections, have been reported to be effective. One drug may overwhelm or neutralize the mechanisms of bacterial resistance, repurposing the antibiotic drug by increasing its efficacy. May be the best-known example of antibiotic synergy is the combination of clavulanic acid with β-lactam antibiotics [(14)]. Antibiotic combination therapy is used to prevent the emergence of resistant microbial strains, treat emergency cases during the process of etiological diagnosis, and to take advantage of antibiotic synergism. This is noted to be effective when two bactericidal agents are combined, but antagonism occurs *in vitro* on combination of a bacteriostatic and a bactericidal antibiotic[(15)] checkerboard technique is an *in vitro* synergy test using to determine the antimicrobial combinations activity. It is a simple to perform and remains to be a widely used technique to assess antimicrobial combinations[(16)]. Aminoglycoside and beta-lactam combinations are the most frequent used for the treatment of many infections especially due to *P. aeruginosa*. Many studies reported these synergistic combinations[(17,18)]. In this study, it is detected that the synergy was obvious between Ceftazidime and Amikacin against *P. aeruginosa* isolates. Also, many reports indicated to the combinations of quinolone and beta-lactam antibiotics and the synergism with several rates was observed [(19, 20)]. In this study, synergy was less effective in resistant strains with Ceftazidime-ciprofloxacin combination. Mayer and Nagy (1999) [(19)] revealed that the combination of third-generation cephalosporin with fluoroquinolones rarely shows synergy. In agreement with the results of current study, Hannan *et al.* (2014) [(21)] showed that among the four combinations evaluated ceftazidime-ceftazidime-meropenem, piperacillin/ tazobactam, ceftazidime-amikacin and ceftazidime-ciprofloxacin, ceftazidime-amikacin was in high rates of synergy in multidrug resistant strains of *P. aeruginosa*. Combinations of aminoglycosides and β-lactams have synergic effects against gram negative isolates of this study. The mechanism of this combination may be due to the action of β-lactams on bacterial cell wall by destruction of peptidoglycan polymers and then easily of the entry of the aminoglycosides into the bacterial cell [(22)].

Out of the total isolates of OM infections, 28 isolates with high antibiotic resistance are selected for detection the Quantitative biofilm formation by Tissue Culture Plate (TCP) method, these isolates were distributed as 7 from 4 species which include (*Pseudomonas aeruginosa, Proteus mirabilis, Klebsiella pneumoniae* and *Staphyllococcus aureus*). Quantification of biofilm formation has been shown in Table (2) and Figure (2).

All isolates (100%) showed biofilm production by TCP method. Strong biofilm producers were 14 (50 %), 10 (35.7%) were moderate and 4 (14.2%) isolates were considered as weak biofilm producers. In this study, the strong biofilm production is the most prevalent in *P. aeruginosa* (7, 100%) followed by *S. aureus* (5, 71.4%), while the most of *P. mirabilis* and *K. pneumoniae* are moderate biofilm producers.

Table (2). Screening of OM pathogenic isolates for biofilm formation by Tissue Culture Plate method.

BACTERIAL SPECIES	Number of investigated isolates (%)	BIOFILM PRODUCTION				Chi-Square (χ^2)
		STRONG	MODERATE	WEAK	NON PRODUCTION	
Pseudomonas aeruginosa	7	7	0	0	0	6.34 **
Proteus mirabilis	7	1	4	2	0	2.08 NS
Klebsiella pneumoniae	7	1	5	1	0	4.52 *
Staphylococcus aureus	7	5	1	1	0	4.71 *
Total	28 (100 %)	14 (50 %)	10 (35.7 %)	4 (35.7 %)	0	6.41 **

* (P<0.05), ** (P<0.01).
