leaving the contraption area in the district of Shatra surrounded by agricultural lands and small villages the station

3. **The station (Fish Farm) third:** Just 15 km from the second substation and is considered one reference where is located near the River Garraf before entering to hand Garraf and surrounded Port Lands uncultivated and localities do not exist around. Separated gill and muscles Fish separately and cut into small pieces and dried oven electric degree 120 ◦ and milled and Nkhalt and digested by acid intensive depending on how [6] and measured trace elements by spectrum atomic absorption flame device and expressed it units (mcg/g dry weight).

Results

The results show as in figures below:

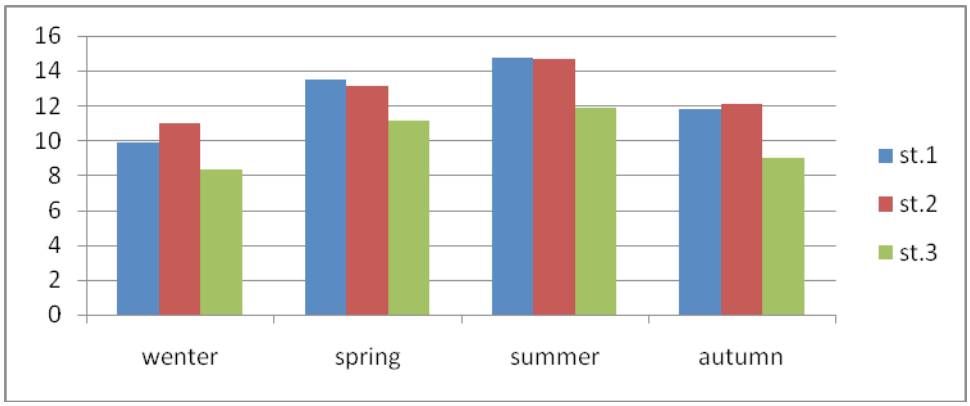

Figure 1: Concentration for cadmium (mg/l) in fish gill of common carp fish in the study stations

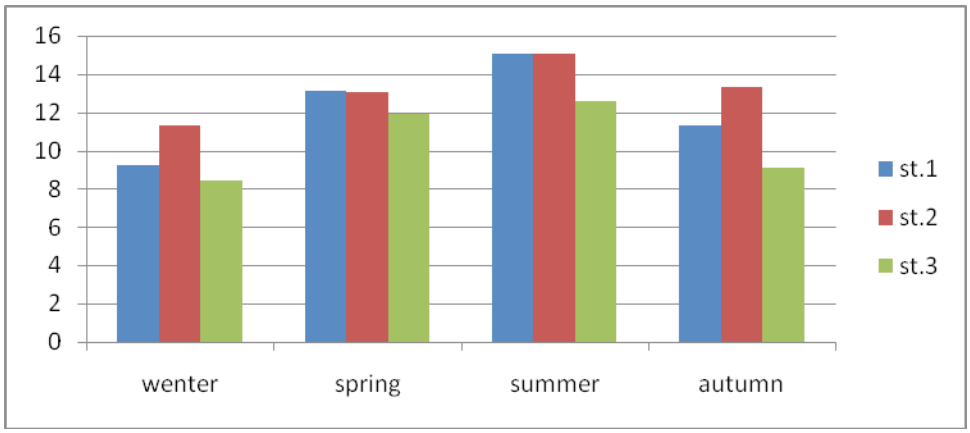

Figure 2: Concentration for lead in fish gill of common carp fish in the study stations

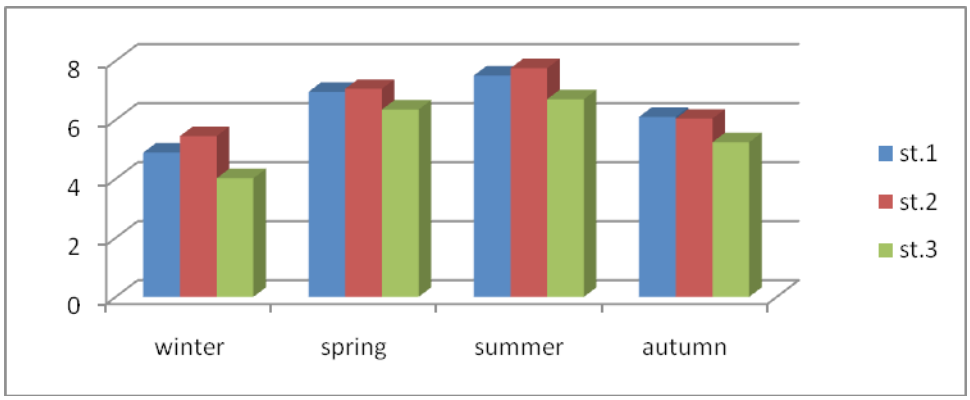

Figure 3: Concentration for cadmium in the muscles of the common carp fish in the study stations

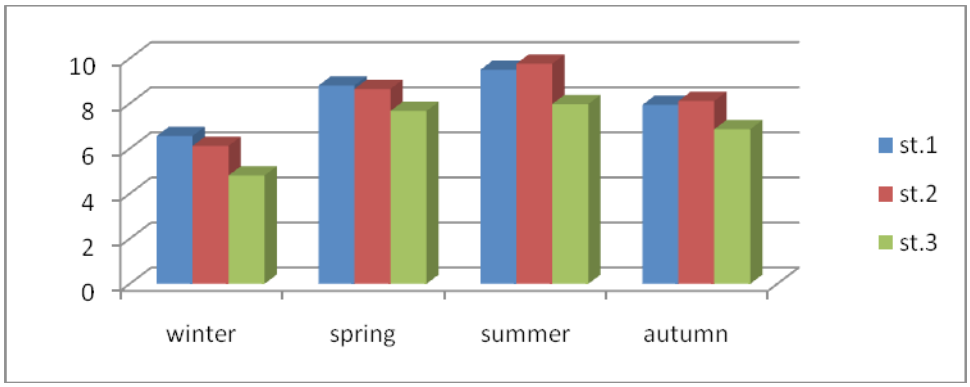

Figure 4: Concentration lead in the muscles of common carp fish in the study stations.

Discussion

The study of fish muscle content of trace elements is important and that which is to know the amount up to which the human body as a Gmaoua key and cheap[3] as the concentration of the components found in the body of water does not reflect the degree of contamination without necessarily accumulation in the neighborhoods[4] the study results showed high cadmium and lead concentration in the gill and muscles Blowfish

Careless for the first, the second station Compared with the third leg the fact that the station (1.2) are similar in pollution sources trace elements waste human, fertilizers and pesticides[8]. The concentration of cadmium and lead is the highest in the gills of it in the muscles because of that first considered the site is important to enter the heavy elements and cause the effects of destructive gill[5], and have their accumulation in the muscles less because of the lack of correlation trace elements muscle protein[6]. The increase in the concenteration careless in the summer due to evaporation, leaving the salts of heavy metals to increase its concentration in the water, which shows its effect by increasing its accumulation in fish as a result of increasing the amount of heavy-element taken from the water[7].

Conclusions

1. Eating gills is safer because it is more exposed and in contact with trace elements.
2. The cause of the accumulation in the tissues of the fish careless that elements in the water freely easier for fish taken from her.
3. The severity of the tendency of these elements to the accumulation in the members fish shows easily lured and its association with elements ubiquitous organ and this form does not exist in a natural state (in the absence of pollution) indicating that they entered the outsourcing of polluting downtown.

Conflict of Interests: Nil.

Ethical Clearance: Take from stations in DhiQar by approval ethical committee.

Funding: Self-funding.

Practitioner and Staff at the Banyumas District Health Office, Central Java

Abstract

Background: The Covid-19 pandemic has spread to 215 countries and territories since the outbreak first occurred in Wuhan, China. Indonesia has also declared the Covid-19 national disaster since 2 positive patients were found on March 2, 2020 and there has been a rapid spread to various regions in Indonesia including Banyumas District. This study aims to determine the risk factors, effective reproduction number and predictions SIR of Covid-19 in the Banyumas District for the period of 16 March - 14 June 2020.

Method: This study is a cross-sectional design. Cases are patients with comfirmed covid-19 in the area. Minimum sample size was 43 and total sample size was 70 people. Univariate analysis was used to describe of characteristics, epiestim to determine effective reproduction number, and SIR model to determine prediction of covid-19.

Result: As of June 14, 2020, in Banyumas District there were 392 suspected cases, 70 confirmed cases, 58 cases were recovered and 4 people died. The characteristics of the confirmed cases were the age group of 15-24 years as much as 21.1%, males 62%, 52.1% have a history of travel to/from out of town, and 91.5% showed symptoms especially fever symptoms as much as 81.7%. The effective reproduction number (Rt) for the period March 16, 2020-June 14, 2020 was 1.81 (0.83-3.35; 95% CrI). SIR model predictions, that the peak of the outbreak will occurred on June 21, 2020 with the number of confirmed cases of 4,312 people.

Conclusions: The covid-19 outbreak in Banyumas District was still out of control and still ongoing. It is recommended to continue to increase discipline of health protocols, get used to wearing masks, keep a distance and wash hands with soap and strengthen tests, traces and treatments and also protect vulnerable groups.

Introduction

Corona virus disease-19 (covid-19) is an infectious disease caused by Severe Acut Respiratoty Syndroma-Corona Virus-2 (SARS-CoV-2) formerly known as 2019-nCov. This disease originated from 41 cases of pneumonia without known cause in Wuhan, Hubei Province, China on December 30, 2019 and there is a history of contact with the seafood market.[1–4]

On March 11, 2020, WHO declared a global co-19 pandemic. This is because in the last 2 weeks there has been an increase in cases outside China 13 times and the number of affected countries increased 3 times.[5,6] As of May 5, 2020, the co-19 pandemic has spread to 215 countries and territories. Globally there were 3,525,116 confirmed covid-19 cases and 243,540 deaths.[7]

While in Indonesia as of May 6, 2020, there were 12,071 confirmed co-19s and 872 deaths. In Central Java, as of June 13, 2020 there were 2,066 positive and 147 people died and became the fourth epicenter after DKI Jakarta, East Java and West Java,[8] while in Banyumas District there were 69 positive people and 4 people died. Characteristics of positive cases for a while as much as 60.6% are male and dominated by adolescents (10-19 years) as much as 16.7%.

At present, most countries, including Indonesia, are preparing for a new normal life, as well as the Banyumas District. WHO has issued public health criteria to adjust public and social health measures in the context of covid-19. According to WHO, the covid-19 outbreak was controlled if Rt <1 for at leat 2 weeks.[9] This study aims to determine the characteristics, effective reproduction number & prediction of the SIR model of Covid-19 disease in Banyumas District, Central Java.

Method

Research Design: This study was an observational analytic study using a cross-sectional design i.e. retrieval data and risk factors are carried out at one time. This study also uses Epiestim software to calculate the number of reproductive effecives and computer equipment to calculate the prediction of the SIR covid-19 outbreak model in Banyumas District.

Research Subjects: The population of this study was sourced from secondary data from the Banyumas District Health Office for the period March 16 to June 14, 2020. Suspect cases were cases that meet the criteria for suspicion according to WHO. Confirmation cases were cases with positive PCR results.[10]

The sample size was determined based on the significance level of 0.05, the strength of the test 80%, the proportion p=q=0,5, obtained a sample size of at least 43 people and in this study the total sample size was 71 comfirmed cases and 392 suspected cases.

Data Collection: The data was sourced from secondary data collected by the Banyumas District Health Office for the period March 16 to June 14, 2020. These data were the results of a survey containing names, addresses, age, sex, date of onset, symptoms and signs as well as travel history from/to outside city.

Effective Reproduction Number (Rt): The effective reproduction number (Rt) is an important parameter to find out whether outbreak control is effective or additional interventions are needed.[11] Rt values represent the number of new secondary cases that are infected from one infective case at time t. If Rt> 1, the possibility of disease will become epidemic, if Rt = 1, the disease becomes endemic and if Rt <1, the possibility of disease will disappear from circulation.[12]

To calculate the Rt in this study using EpiEstim software based on Excel developed by Cori et al in 2013[13] and corrected by Thomson et al in 2019[14]. The mean serial interval (SI) and standard deviation (SD) using the results of the study of Tindale et al, namely the average SI = 4.56 and SD = 0.95.[15]

Prediction SIR Model: The SIR model as the initial formula that has been formulated by Kermack and McKendrick[16] is a differential systemS (t); I (t); R (t); $\gamma > 0$:

$$St = -SI; \quad (1a)$$

$$It = SI - \gamma I; \quad (1b)$$

$$Rt = \gamma I; \quad (1c)$$

The interpretation of this model is very easy. The Susceptible individual population decreases through interaction with infective people, whose numbers increase through this mechanism. On the other hand, the population of infective individuals decreases because some individuals recover or die, and thus fill the Recover class. This epidemic model is known as the Susceptible, Infective, and Recover/Removed (SIR) epidemic model. The SIR model is very useful for predicting the future, end and peak of epidemics and other activities related to epidemic diseases.[17]

In this study, R = number of patients who recovered + who died. The description of the SIR model for Recover returning to Susceptible because the world outbreak of COVID-2019 has developed that patients who recover can be re-infected.[18]

S in this study is based on the estimated number of people who should be examined according to WHO standards of 1/1000 population per week.[19] During the period of March 16 to June 14, 2020 (13 weeks), the population of Banyumas District was 1,840,152 people, so 1,840 x 13 = 23,922 people as Suspected (S).

Data Analysis: Secondary data were analyzed to describe the characteristics of confirmed cases according to age group, sex, travel history to/from out of town, symptoms and signs. Rt was analyzed using EpiEstim to obtain median Rt and 95% CrI. The prediction of the SIR model with computer software was analyzed to determine the prediction of the outbreak peak and the end of the covid-19 outbreak in Banyumas District.

Ethical Clearance: This study was approved by the Commission on Health Research Ethics, Medical School, Jenderal Soedirman University (Unsoed) with Ref no: 151/KEPK/VI/2020.

Results

Banyumas District is one of the districts in Central Java, Indonesia. Banyumas District consists of 27 sub-districts and 331 villages/outlands with an area of 132,759 hectares and a population of 1,840,152 people. During the period from March 16 to June 14, 2020, there were 392 suspected cases, 71 confirmed cases, 58 cases were recovered and 4 cases died due to covid-19. Characteristics of 71 confirmed cases when first treated, are presented in Table 1.

Table 1. Characteristics of Comfirmed Covid-19 Cases

	Characteristics	n	%
1	**Age Group (year)**		
	0-<5	2	2.8
	5-14	5	7.0
	15-24	15	21.1
	25-34	10	14.1
	35-44	10	14.1
	45-54	8	11.3
	55-64	11	15.5
	65-74	5	7.0
	75-84	5	7.0
	>84	0	0
2	**Gender**		
	Male	44	62.0

	Age group (year)		
	45-54	2	50,0
	55-64	1	25.0
	75-84	1	25.0
	Gender		
	Male	2	50.0
	Female	2	50.0

According to Table 1, the 15-24 years age group most suffering from covid-19 were 21.1%, 62% were male, 52.1% had a history of travel to/from out of town and 91.5% showed symptoms with main symptoms were fever (81.7%) and cough (46.5%).Cases that have died amounted to 4 people or a mortality rate of 5.6% with the age of 45 years and over and have comorbid diseases. Effective reproduction number (Rt) for the period March 16 to June 14, 2020, obtained Rt = 1.81 (0.83-3.35; 95% CrI)as shown in Figure 1. In the past 14 days, the trend of Rt can be seen in Table 2.

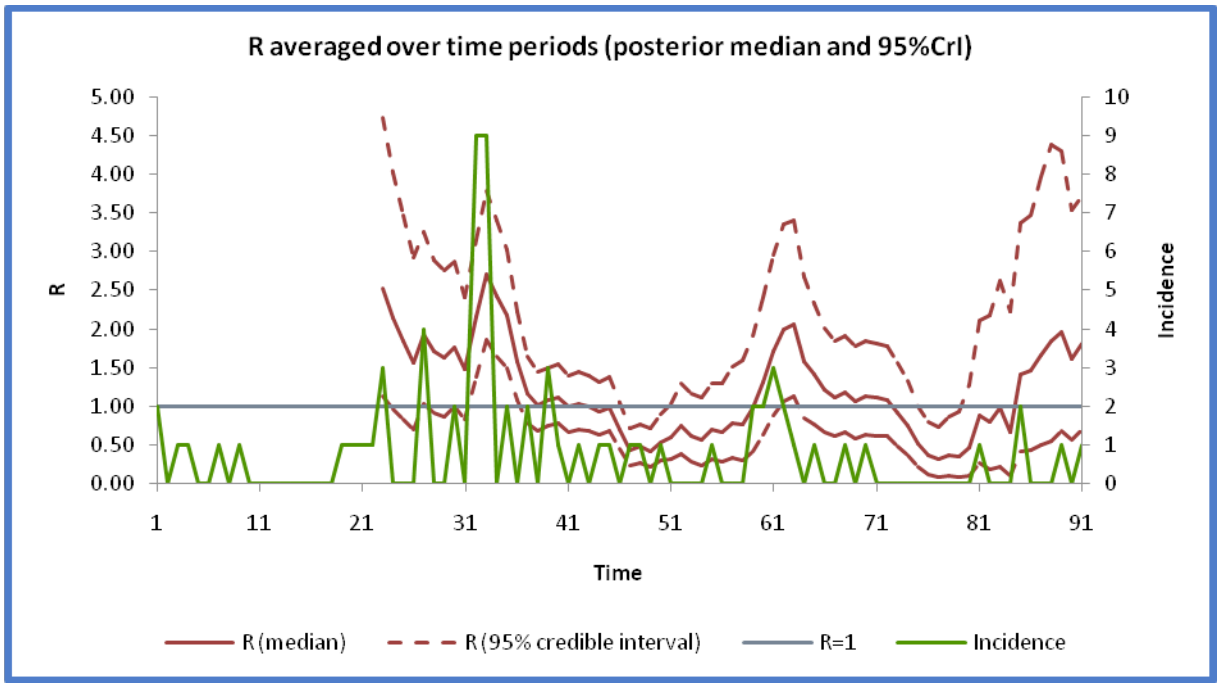

Figure 1. Trends of Effective Reproductive Number (Rt) of Covid-19 in Banyumas District, Period March 16 to June 14, 2020

Table 2. Trends of effective reproductive numbers (Rt) of covid-19 for the last 14 days

No.	Date	0,05 Q	M	0,95 Q
1	01-Jun-20	0,14	0,36	0,77
2	02-Jun-20	0,1	0,34	0,81
3	03-Jun-20	0,15	0,47	1,12
4	04-Jun-20	0,33	0,89	1,87
5	05-Jun-20	0,25	0,8	1,9
6	06-Jun-20	0,3	0,97	2,29
7	07-Jun-20	0,14	0,67	1,89
8	08-Jun-20	0,52	1,41	2,97
9	09-Jun-20	0,54	1,45	3,07
10	10-Jun-20	0,62	1,66	3,51
11	11-Jun-20	0,68	1,84	3,88
12	12-Jun-20	0,83	1,96	3,84
13	13-Jun-20	0,68	1,61	3,15
14	14-Jun-20	0,83	1,81	3,35

According to Table 2, Rt Covid-19 from 1-14 June 2020 (last 14 days) still obtained Rt <1 but upper bond> 1 & Rt> 1 (red color). The Covid-19 outbreak in Banyumas District was predicted for the next 100 days from June 14, 2020 with the SIR model and the results are presented in Figure 2 and Table 3.

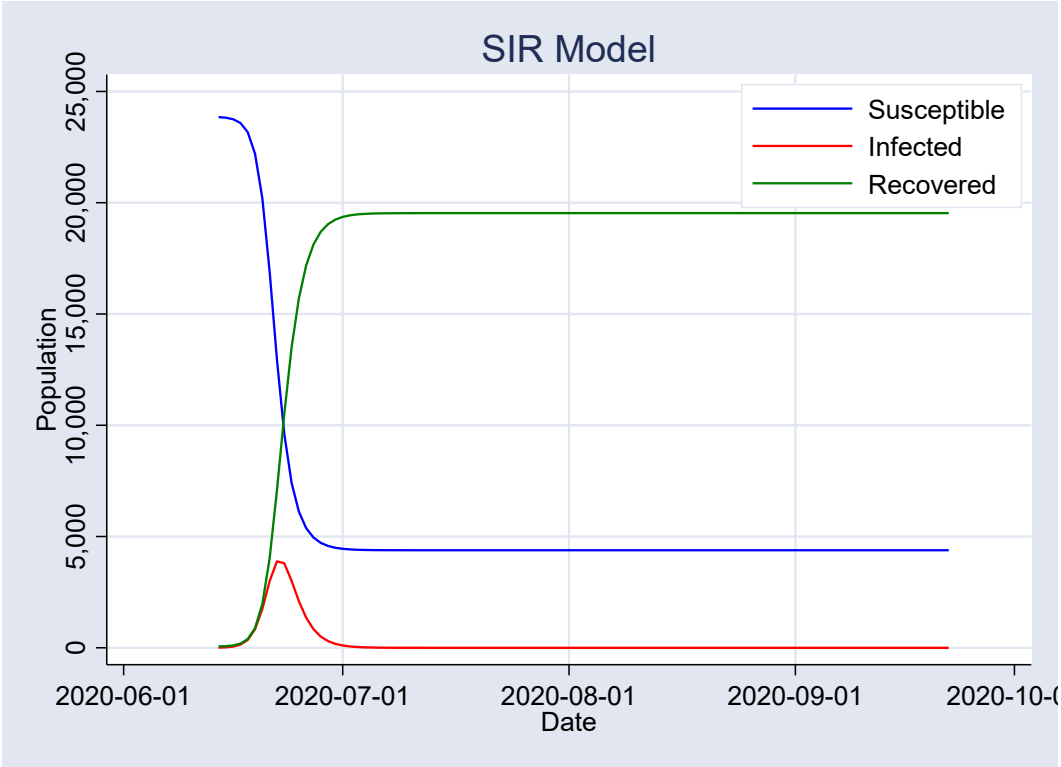

Figure 2. SIR Model of Covid-19 Outbreak in Banyumas District

Table 3. SIR Model of the Peak and end of Covid-19 Outbrek

Population	**2020-06-14**	**2020-06-22**	**2020-09-22**
Susceptible	23,848	12,948	4,348
Infected	9	3,886	0
Recovered	62	7,083	19,534
Total	**23,918**	**23,918**	**23,918**

Discussion

The 15-24 years age group is the highest group suffering from confirmed covid-19 cases in Banyumas Districs. It is appropriate that coivd-19 can affect all ages.[20] Specifically, in Banyumas District, this age group is related to school-age children where at the beginning of the outbreak, no action has yet been taken to close the learning process at school. Some schools even have study tours outside the city. Of course, this increases the risk of covid-19 transmission. There were 52.1% of confirmed cases have a history of travel from/ out of town and certainly increase the risk of covid-19 transmission.[21]

The comfirmed covid-19 cases were 62% male. Covid-19 sufferers are mostly male, this is associated with the possibility of men smoking more, and women have protection from the X chromosome and sex hormones which play an important role in innate immunity and adaptation.[22–24]

There were 4 cases of death (mortality rate 5.6%) due to covid-19 and age 45 years or more and had comorbid disease. Old age and the presence of chronic comorbid diseases can increase the fatality of covid-19 disease. Although the covid-19 fatality rate at the age of 80 years or more between China and Italy is the same.[22,25] According to the Centers for Disease Control and Prevention (CDC) the age group (≥65 years) and all ages with comorbid diseases such as chronic lung disease, moderate-severe asthma, heart disease, immunocompromis (cancer treatment, smoking, organ transplantation or bone marrow, immune deficiency, uncontrolled HIV/AIDS, prolonged use of corticosteroids, and other treatments that weaken

the immune system), severe obesity, diabetes mellitus, chronic kidney disease, and liver disease, increase the risk of suffering from severe covid-19.[20]

The effective reproduction number (Rt) in the last 14 days, namely June 1, 2020 to June 14, 2020, is obtained Rt> 1.[9] Predictions with the SIR model that the peak of the outbreak will occur on June 22, 2020 with the number of cases as many as 3,886 and the outbreak will subside on September 22, 2020. This indicates that the covid-19 outbreak in Banyumas Districs has not been controlled. Therefore, efforts to increase discipline on health protocols, to get used to using masks, keep a distance from others at least 1-2 meters and wash hands with soap. contact tracing, testing and treatment continue to be improved and protect vulnerable groups.

Conclusions

The covid-19 outbreak in Banyumas Districs is still not controlled. Therefore, it is still necessary to remain disciplined about health protocols and other prevention efforts. Tracing contacts, testing and treatment continues to be strengthened while still protecting vulnerable groups.

Conflict of Interest: The authors declare that they have no competing interests.

Medico-Legal Outlooks in Preventing Traffic Violations and Accidents by Enforcing the Structure and Function of the Police Unit

Yusriyadi

Lecturer at Faculty of Law, Diponegoro University, Indonesia

Abstract

By using medico-legal outlooks, the focus of this research is the structure, function and role of the Dikyasa Unit as part of law enforcement by the Police. This focus is normatively found in Law Number 22 of 2009 concerning Road Traffic and Transportation. There are two problems, first, what is the structure, function and role of the Dikyasa Unit and what are the two social and personal factors that affect the function and role of the Dikyasa Unit. To analyze this problem, a research was conducted in the Legal Area of the Semarang Police as an alternative legal study that positions the law in a broader community context. The research findings show that firstly, the Dikyasa Unit is in charge of fostering community participation and traffic education and secondly there are social and personal factors that affect the function and role of the dikyasa unit.

Keywords: *Traffic violations, accidents, police, function, medico-legal perspective.*

Introduction

The structure, function and role of the Dikyasa Unit then in preventing traffic violations and accidents, are essentially part of law enforcement by the Police. The Dikyasa Unit then provides guidance and outreach to the community. The National Police, as one of the road transport traffic stakeholders, plays an active role in preventing traffic violations and accidents.

As the expected outcomes of Law No. 22 of 2009, the World Health Organization (WHO- World Health Organization) made an official statement, that by 2030 traffic accidents are the fifth cause of the "top ten" human deaths. In Indonesia, the death toll from traffic accidents is increasing. In 2013, there were 28,161 people, an increase of 1.8 percent compared to 2012 with 25,944 people who died. Article 2 of Law no. 22/2009 mentions road transportation as one of the national transportation based on the principles of benefit, joint effort, fairness, equality, balance, public interest, integration, legal awareness and self-confidence. The goal is to create road traffic and transportation services in a safe, secure, orderly, smooth and integrated manner. The development of transportation demands the availability of means of transportation with various implications. The more means of transportation, the more road users are at risk of driving safety. As the number of road users increases, the number of traffic violations and accidents increases. These problems underlie the importance of this research.

Problem: There are two problems, namely: First, what is the structure, function and role of the Dikyasa Unit? Second, what social and personal factors influence the function and role of the Dikyasa Unit?

Literature Review: This research can be called an alternative legal study that positions law in the context of a broad society[1]. Qualitative data consists of primary and secondary data. The data sources are in the form of words and actions, accompanied by additional data such as documents[2]. Primary data sources were obtained from informants, namely members of the Dikyasa Unit through observation, interviews, document

interpretation. Researchers as participant observe/key instrument. Interpretation and checking of the validity of the data using technical analysis models[3,4]. Researchers as participant observe/key instrument. The theory used is the theory of law enforcement from Chambliss & Seidmanand Soekanto theory of the effectiveness of law, normative logic, not emphasized and more to empirical reality[5,6].

Two theories are used to analyze two problems, namely Chambliss & Seidman's theory of law enforcement and Soerjono Soekanto's theory of the effectiveness of legislation[7]. The two theories are relevant for use in socio legal studies. Here, law is not only a normative document, but also as a socio-cultural symptom[8]. Normative logic (deductive-normological) is not emphasized, but rather empirical reality. By Chambliss & Seidman, this empirical reality is called social force and individual force[5]. Apart from these two theories, the concept of operational management of the Traffic Police is also used.

Structure, Function and Role of Dikyasa Units: Law enforcement essentially is to realize the objectives of law, namely justice, certainty, and benefits[9].Law is conceptualized as statutory regulation (*Sollen*) which must be realized, as well as as a social institution, so that this type of research is non-doctrinal. Law is seen as both the dependent and independent variable.

Initially, the analysis of the research results would be compiled based on field findings, but due to the Corona Virus Disease 2019 (COVID-19) outbreak which was declared a global pandemic by the World Health Organization (WHO) March 11, 2020, the research was not carried out optimally. Not maximizing, especially after the publication of the Semarang Regent Instruction No. 2 of 2020 concerning the Implementation of Restrictions on Community Activities in the Context of Accelerating the Management of Corona Virus Disease (Covid-19) as a protocol, so that the analysis is more based on literature study.

Affecting Social and Personal Factors: Law is made to be implemented, therefore it is not surprising that people say that law can no longer be called law when it has never been implemented[10]. Research on the role and function of this unit in power also wants to examine these roles and functions in the realm. Empirical, so that it is consistent with the notion of law as something that must be implemented.

In particular, the form of law can be seen through explicitly formulated rules. Within those legal principles, actions that must be carried out are contained in none other than law enforcement[10]. Discussing the function and role of the unit dikyasa essentially also talks about the implementation of abstract legal ideas (*Sollen*) into reality. From here we enter into a discussion about the operation of law in society which includes the role and function of the unit in power. The roles and functions of the dikyasa unit occupy an important and decisive position in preventing traffic violations and accidents. Legal objectives can ultimately become a reality in or through the roles and functions of the unit in power.

The role and function of the dikyasa unit is a function of the work of the influence of social and personal forces. It cannot be ignored the fact that law enforcers, cq unit dikyasa and adat community members will tend to give their own interpretation of the functions and roles that must be carried out. There are social and personal forces. This research stems from the awareness to distinguish law in the books and law in action.

The function and role of the unit is closely related to the law enforcement system, whose elements are (1) substance, (2) structure and (3) culture. To study the social and personal factors that contribute to the implementation of the function and role of the unit in power, the theory of Chambliss & Seidman[5], theory Soekanto & Mamudji[11] is used regarding the effectiveness of a statutory regulation.

In addition to this theory, the concept of literature on the operational management of the Traffic Police is also used. This management refers to a process of planning, organizing, implementing, supervising and controlling in order to carry out police operations in order to achieve predetermined objectives effectively and efficiently.

Measuring the progress of an organization at all levels always concerns the neatness of the elements in order to achieve its goals. A neat organization, for example a crime organization, if it is neatly organized, it is often eradicated by the unorganized truth enforcers. Management has a literal meaning as "the art of implementing and managing" it is very crucial for the implementation of tasks in the organization. The art of implementing and managing this in the context of carrying out organizational tasks is in principle building synergy of every element of the activities involved in it.

The implementation of the functions and roles of the dikyasa unit is essentially a manifestation of legal ideas, or legal objectives become reality. The implementation of the functions and roles of the dikyasa unit is part of law enforcement. In understanding the implementation of these functions and roles, it can be started by analyzing the process of the operation of law in society.

William J. Chambliss & Robert B. Seidmanbasically reveals about the process of law operation in society[5]. This process is determined by the operation of the entire social and personal complex of each of the stakeholders. This theory of the operation of law in society can be used as an analogue regarding the implementation of the function and role of the unit in power. The implementation of the functions and roles of the Dikyasa Unit is determined by the operation of the entire social and personal complex of each of the role holders, namely the parties involved in it. Through Chambliss & Seidman's theory, it can be described, revealed and even explained the implementation of the function and role of the unit in the field.

In line with Chambliss & Seidman[5], Satjipto Rahardjo[12], states that the enactment of law as a process involves various elements, namely (1) the regulations themselves, (2) citizens as the regulatory environment, (3) implementing bureaucratic activities and (4) the existing and participating socio-political-economic-cultural framework determines how each element in the law carries out what it is a part of.

These elements can be seen in relation to one another in a dynamic interaction process, for example the relationship between statutory regulations (cq. The National Police Law and others), and citizens using the means of transportation as their custom. These laws and regulations are seen in the "expectation and performance patterns" (expectation and performance), which contains the hope that citizens, as legal codes, can implement them at a practical level as a means of fulfilling their obligations. Even though normatively these functions and roles have been "punished" in the statutory regulations, this does not mean that since then the roles and functions of the powerful unit have been completed.

The implementation of the functions and roles of the dikyasa unit is a sub system of the traffic law enforcement system. It contains elements as subsystems, namely (1) substance, (2) structure and (3) culture. The substance relates to its normative aspects, namely positive law which regulates the structure, function and role of the unit in power. Satjipto Rahardjo[12] states that the enactment of law as a process involves various elements, namely (1) the regulations themselves, (2) the citizens as the customary rules, (3) the activities of the implementing bureaucracy and (4) the socio-political-economic-cultural framework exist and participate determine how each element in the law carries out what is part of it. In this research, these elements are seen in a dynamic interaction process, for example the relationship between laws and regulations (cq. The National Police Law, etc.) and the customs, namely citizens using transportation, the laws and regulations can be seen in the "pattern of expectations and implementation". Normatively, these functions and roles have been "punished", but that does not mean that since then the roles and functions of the unit have been resolved.

The implementation of the functions and roles of the dikyasa unit is essentially a manifestation of legal ideas, or legal objectives become reality. The implementation of the functions and roles of the dikyasa unit is part of law enforcement. Referring to Chambliss & Seidman, in analyzing the function and role of the unit dikyasa, it begins with analyzing the process of the operation of law in society[5]. This process is determined by the operation of the whole complex of social and personal forces of the role holder[13]. This means that the effectiveness of legislation is influenced by several factors, namely legal/statutory factors, law enforcement, facilities or facilities, society, and culture[11]. These factors are closely related, because they are the essence or measure of the effectiveness of law enforcement.

Conclusion

Within the scope of the organization, the Semarang Police has a Dikyasa Traffic Unit as an element of implementing the main tasks that is under the invisible, tasked with fostering community participation and traffic education. In carrying out its duties, the Dikyasa unit carries out the function of carrying out community participation fostering through cross-sectorial cooperation, carrying out public education in the field of traffic, carrying out studies and engineering of traffic problems, carrying out coaching and counseling to students, communities, driving schools, and groups, implementing coordination with related agencies regarding cross-sectorial cooperation on traffic problems and innovation in the traffic sector. The unit dikyasa,

led by Kanit Dikyasa and in carrying out its duties is responsible to the visible and then under the control. The function and role of the unit is arguably part of law enforcement. The social and personal factors that dominate each other in the implementation of the functions and roles of the powerful unit in preventing traffic violations and accidents, the process of law operation in society, are determined by the operation of the whole complex of social and personal power of the role holders.

Abstract

Background: Pregnant women with SARS-CoV-2 infection must be identified and treated early because they are a group susceptible to higher risk as more cases of infection appear, the timely diagnosis will allow us to select which patients merit maternal surveillance. Much closer fetal and/or timely hospital admission with an immediate impact on emergency clinical practice

Objective: To assess the knowledge and practice of pregnant Iraqi women about COVID-19 preventive measures.

Patients and Method: A cross sectional study conducted at the Private clinics for Gynecology and Obstetrics in Baghdad/Iraq for two months, from 1 of May 2020 to the end of Jun 2020. The study sample is 400 pregnant women that are attending private clinics for antenatal care, studying their knowledge about COVID-19 infection and their approach.

Results: The Knowledge score level were found Inadequate in (72%) of the participant and adequate in (28%), the main source of information about the COVID-19 prevention in multiple answers question was TV, which presented in 338 (84.5%), then 234 (58.5%) from family and friends, 229 (57.25%) and 103 (25.75%) mentioned that their information from HCWs. 2/3rd of the participants were presented with poor practice (67.25%) while less than 1/3rd (32.75%) with good practice**.**

Conclusion: Knowledge score level were found Inadequate in (72%) of the participant and 2/3rd of the participants were presented with poor practice (67.25%) while less than 1/3rd (32.75%) with good practice**.**

Keyword: *COVID-19, Knowledge, Practice, Pregnant, prevention, infection.*

Introduction

On December 2019, an outbreak of a respiratory syndrome was emerged in Wuhan in China that alerted severe acute disease (SARS) caused by a new Coronavirus (SARS-CoV-2), on March 2020, the WHO declared the disease as pandemic, To date, SARS-CoV-2 infected millions of peoples and causing several thousands of death and it still progressing in many countries.(1)

The risk factors that are associated with both SARSas higher mortality are age over 65 years, obesity, diabetes, hypertension,The hypothesis related to these comorbidities is the over expression of ACE 2 receptors, which could facilitate the entry of the virus into the pneumocyte, where it would replicate exponentially and attract to leukocytes and macrophages that would produce pro-inflammatory cytokines that would give rise to SARS. So far, the evidence is inconclusive as

to whether pregnancy confers greater susceptibility to serious complications and vertical transmission of mother-fetus.[2] However, the data are very limited by the low incidence of the disease, so only in 32 cases of pregnant women with SARS-CoV-2, 7 (22%) were asymptomatic, 2(6%) were admitted to the intensive care unit, 15(47%) developed preterm delivery, 1(3%) developed stillbirth, and there was a neonatal death.[3]

The infection by the new Coronavirus SARS-CoV-2, is an unprecedented pandemic and therefore a public health emergency, highly contagious and producing severe acute respiratory syndrome (SARS). The incubation period is 3-7 days, but can vary between 1-14 days.[4] Fever is the most frequent symptom contributed for 88.7%, followed by cough in 67.8% of cases, myalgia, sputum dyspnea, sore throat, headache, and diarrhea in a rate ranged 3.8% to 38.1%, Complications such as pneumonia with infiltrates bilateral, syndrome of distress respiratory acute, arrhythmia, acute kidney injury, cardiac abnormalities and liver damage are common in symptomatic patients with comorbidities.[5]

The transmission of diseases is primarily, by direct person-to-person contact transmission between infected and non-infected individuals.[6]

Pregnant women do not appear to be more susceptible to contracting the infection, nor to presenting serious complications, but the existing data are limited.

In any case, pregnant women with SARS-CoV-2 infection must be identified and treated early because they are a group susceptible to higher risk as more cases of infection appear, the timely diagnosis will allow us to select which patients merit maternal surveillance -Much closer fetal and/or timely hospital admission with an immediate impact on emergency clinical practice. [7]

There is little evidence about the possibility of mother-fetus transmission. As the pregnant patient is classified as a vulnerable group there is no solid evidence of a higher risk of infection or complications, all patients suspected having SARS-CoV-2 infection should be referred to a COVID referral unit to perform aSARS-CoV-2 diagnostic molecular test. Timely referral of all pregnant patients suspected of SARS-CoV-2 infection to specialized COVID units with obstetric care are recommended.[8]

On the other hand, infected pregnant women with decreased fetal movements, vaginal bleeding, severe headache that does not go away with pain reliever, tinnitus, rupture of membranes, sudden and significant edema of the lower extremities with high suspicious symptoms or a serious symptom, it is required to transfer by ambulance to the nearest COVID referral center. [9]

The patient must wear a surgical mask at all times and must be sent to the special isolation zone established for each hospital unit. Avoid entrance of the companion who must wait outside the building or in the waiting room. The most important thing is to assess whether the patient has serious features that require an early intervention. For this reason, the first thing to do is to assess whether the patient is serious or not and then assess for the diagnosis of COVID-19 infection. [10]

Treatment of COVID-19 during pregnancy still under debate; there are more than 49 randomized clinical trials in the world in search of a cure for SARS-CoV-2 infection. However, of the proposed treatments, their safety, effectiveness, dose, stage of disease to be administered, and safety during pregnancy are still unclear. Treatments such as Hydroxychloroquine are safe in pregnancy and appear to be promising, however, information on its efficacy and safety, as well as its dose and stage of disease to which it should be administered comes from non-randomized studies and not blind.[11] Every pregnant woman should go for obstetric reassessment in a specialized referral hospital. Fetal viability in all trimesters and fetal weight will be added by percentile calculation of weight for gestational age and Doppler (in cases less than 10th percentile of weight) in third trimester. [12]

There is evidence that post-infection patients remain positive for SARSCoV-2 infection for 7 days after the resolution of the clinical picture.

Patients with a negative test should rule out influenza or other infectious pathologies. These patients should be managed according to their symptoms or obstetric pathology of preference in hospitalization area outside of isolation and out of risk of infection with COVID-19.[13]

Clinically, pregnant women during her hospital stay must be kept in isolation. It is not contemplated accompaniment by family. The patient should be monitored for pulse-oximetry and vital-signs regularly at least 4 times a day and fetal heart rate monitoring 1 time a day. Terminating a pregnancy in a patient with SARS-CoV-2, in stable patients there is no indication to interrupt the pregnancy. Whenever possible. The decision

to terminate the pregnancy in stable patients will be done under multidisciplinary consensus due to unfavorable evolution according tomaternal deterioration. [14]

Maternal and fetal well-being should be monitored. In the case of fetal surveillance,conducting continuous electronic monitoring of fetal heart rate for 20 minutes, can help us identify changes in fetal physiology reflected in normal patterns and abnormal of it.[15] Postnatally, it is unknown if infection with SARS-COV2 can be pass through breast milk and there is a little evidence about SARS-CoV in mother's milk. Recent studies documented negative evidence about the transmission through breast milk and all samples were reported negative. Currently experience is limited and it is a subject under investigation.[16]

Aim of the Study: To assess the knowledge and practice of pregnant Iraqi women about COVID-19 preventive measures.

Patients and Method

A cross sectional study conducted at the Private clinics for Gynecology and Obstetrics in Baghdad/Iraq for two months, from 1 of May 2020 to the end of Jun 2020. The study sample is 400 pregnant women that are attending private clinics for antenatal care, studying their knowledge about COVID-19 infection and their approach.

A detailed questioner from each patient after taking her consent verbally for participation, it should include the following: patient educational state and residence and home conditions.

The questionnaire included: information about the virus, did she hear about it, form where she heard,, does she believe about it, is the virus the same to common flu, what causes this disease, transmission mode and duration of symptoms since transmission, how patient suspect infection, how serious she thinks the disease, could it be asymptomatic, who can get the disease, does she think that pregnant women are liable to get it more than general population, does she think it is more severe during pregnancy, how does it spread, what can kill the virus, what are the protective personal approaches, does she believe and practice the following: social distance, hand washing, wearing mask, not contact with suspected or sick people, isolation if suspected, cleaning surfaces, using antiseptics, consult a doctor if suspect symptoms.

Statistical Analysis: A pretested and validated questionnaire was used to collect the data. Data analysis was done using SPSS version 23

Results

As shown in figure 1 the main age group were between (20-29) years old as (50.5%) of the participants were found in this group, (23.75%) was in age group (30-39). 19%) in <20 years and (6.75%) in ≥40 years.

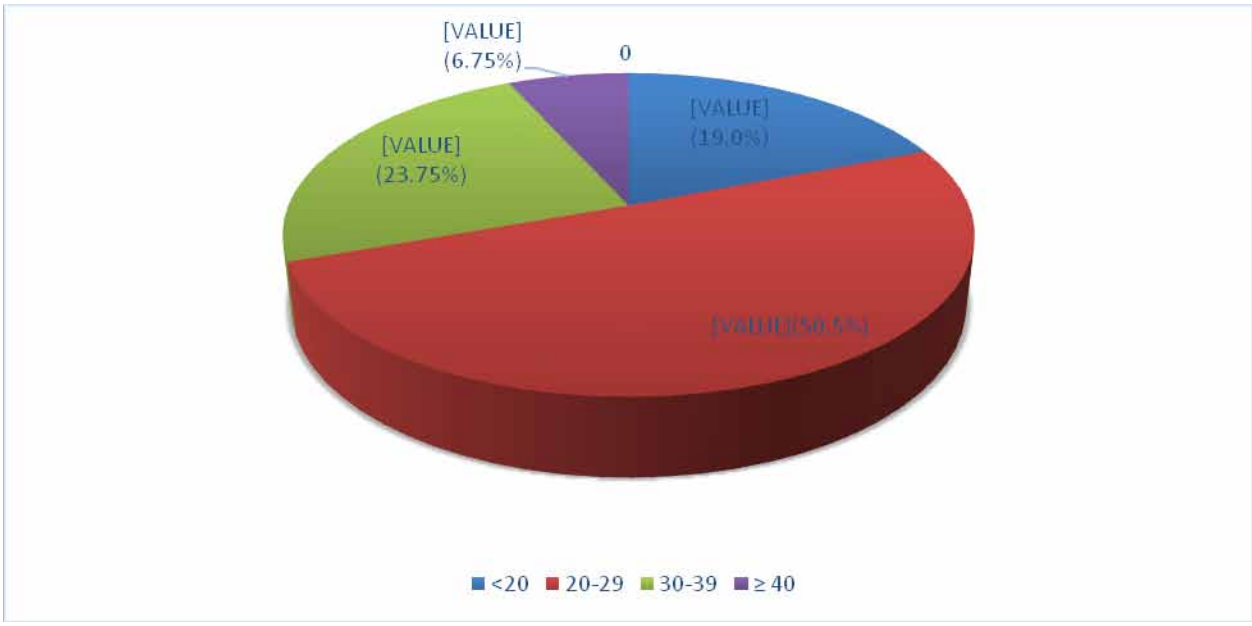

Fig 1: Age distribution of the studied group

Table 1 show that the Knowledge score level were found Inadequate in (72%) of the participant and adequate in (28%)

Table 1: Knowledge score level

Variable		N	%
Participants' knowledge level about COVID-19	Inadequate	288	72.0
	Adequate	112	28.0
Total		**400**	**100.0**

The main source of information about the COVID-19 prevention in multiple answers question was social media, which presented in 338 (84.5%), then 234 (58.5%) from family and friends, TV in 229 (57.25%) and 103 (25.75%) mentioned that their information from HCWs (table 2).

Table 2: Sources of their information

Source of information*	No	%
Social media	338	84.5
Family and Friends	234	58.5
TV	229	57.25
HCWs	103	25.75

*Multiple Responses

384 (96%) of the pregnant women heard about corona virus at the time of the study while 16(4%) don't heard about it (fig 2).

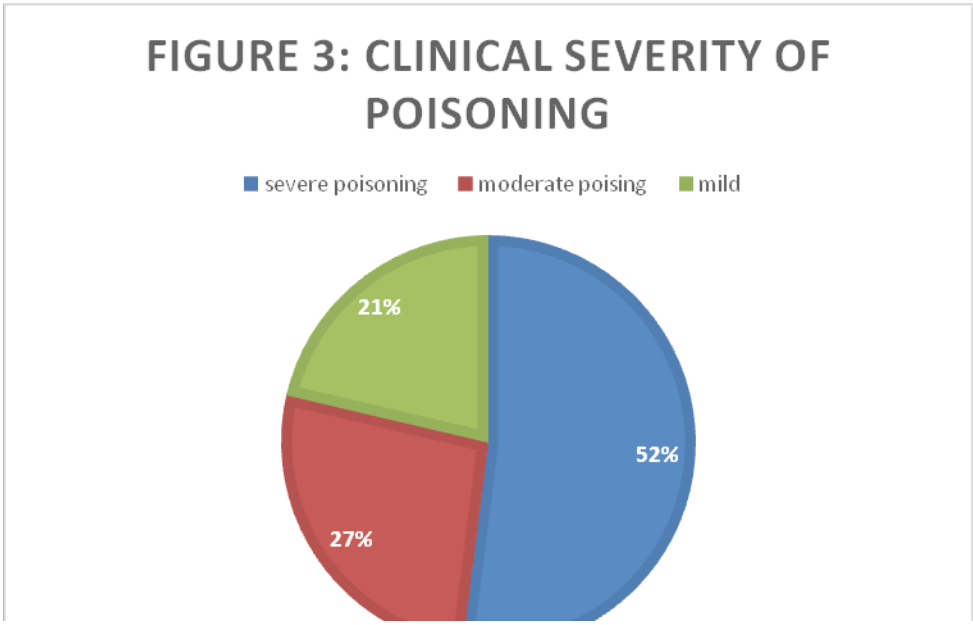

Fig 2: Heard about Novel coronavirus

Table 3, mentioned that about 2/3rd of the participants were presented with poor practice (67.25%) while less than 1/3rd (32.75%) with good practice

Table 3: Practice level about prevention of COVID-19 infection

Variable		N.	%
Participants' practice level about prevention of COVID-19	Poor	269	67.25
	Good	131	32.75
Total		**400**	**100.0**

For the participant practice response for preventing COVID-19 show that 73 (18.25.0%) choose the washing hands frequently as major preventive way, 59 (14.75%) said that a distance for 2 meters and more between the people can prevent the infection with disease. 67 (16.75%) choose do not touch eye, nose and mouth with hands, 123 (30.75%) choose wearing mask was the common way to prevent the infection, and 78 (19.5%) mentioned staying home was the way to prevent infection with the disease (fig 3).

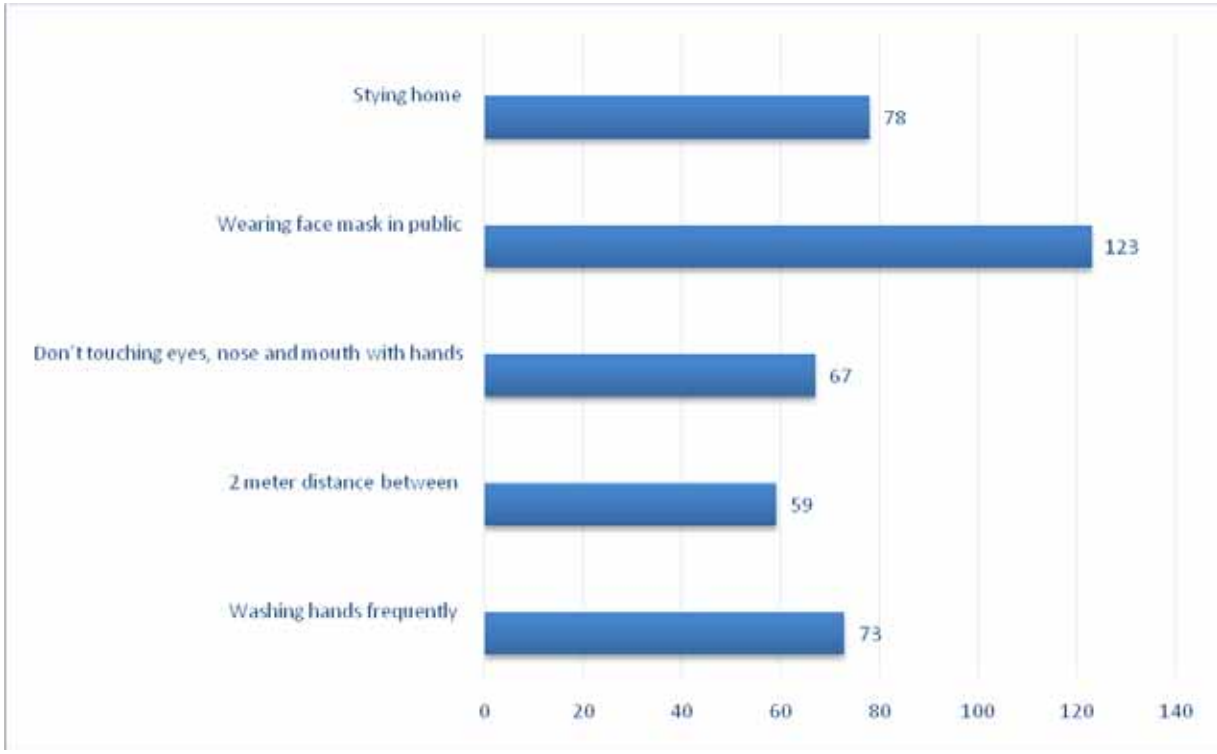

Fig 3: Response of participants among practice of preventing COVID-19

Discussion

The current study provide a shed light about the level of knowledge and practice among preventive measurement of COVID-19 infection in pregnant Iraqi women. The current study show that the level of knowledge were inadequate in about 3/4th of the participants, which is not in agreement with Nawafor J et al, [17] study carried in Nigeria, revealed that (60.9 %) of the pregnant women were presented with adequate knowledge. This may be due to their people trusted to the news when heard from their government that is opposite to our peoples.

The main source of information of the participants in the present study about the COVID-19 prevention in multiple answers question was TV, then family and friends, lastly was from HCWs. Which is in agreement with Bekele D et al,[18]study when they revealed that social media were the main source of information for the participants, then TV. Moreover,Olapegba et al., found that media was the main source of their information. [19]

The majorities of the respondents were heard about the COVID-19 at the time of the study, this is more than that found in a study carried by Ikhaq A et al, in Pakistan found 90% of the respondents were heard about the disease. [19]GeoPoll et al in their survey carried on three African countries revealed that more than (94%) of the participants were heard about the COVID-19. [20]

In the present study participant said that the most common way to prevent the infection were by do not touch eye, noseand mouth with hands (30.75%), then (19.5%) mentioned staying home. This is not in agreement with Azlan A et al, study carried in Malaysia when found that proper washing hand is the common way to prevent infection with COVID-19 then avoiding crowded area. And the least common was those choosing wearing of face mask.[21] Poor practice were common in the present study while Al-Hanawi M et al in their study done in Saudi Arabia revealed good practice score with good knowledge score in the studied group. [22]

Conclusion

Knowledge score level were found Inadequate in (72%) of the participant and 2/3rd of the participants were presented with poor practice (67.25%) while less than 1/3rd (32.75%) with good practice**.**

The Study Effects of *Quercus infectoria* on the Oral Environment in Gingivitis Patients

Ali Hasanain Alhamadani[1], Rana Talib Al-Muswie[2], Sameerah Jameel Tarfa[2]

[1]Lecturer, Instructor at Nursing College/Al-Muthanna University. Iraq,
[2]Lecturer. Instructor at Dentistry College/Thi_Qar University. Iraq

Abstract

Gingivitis is an inflammatory response of the gingival tissues to the metabolic products and pathogenic toxins of bacteria found in oral gingiva. Clinical indicators are redness, edema and swelling of the local gingival tissue.

Study comprised of 35 participants of age between 25-45 years who were clinically examined and divided into three group gingivitis of female, gingivitis of male and healthy control, These were classified according to the values of gingival index score.

Q. infectoria were applied topically to participants were suffering from gingivitis, In addition Strips of pH indicator paper were also used to diagnose the effect of *Q. infectoria* on the pH of the oral pathophysiology. Diagnoses and follow-up product were performed in a dental clinic under the supervision of a dentist by used gingival index for two weeks.

The progress of gingival measured in female group in terms of mean, standard deviation and variance were 0.7,0.135 and 0.018 before treatment while 0.3, 0.125 and 0.015 after treatment however for male group were 0.678, 0.189 and 0.03 before treatment while 0.291, 0.132 and 0.01 after treatment.

We observed the great efficacy of the herb product against gingivitis In addition, Significant changes in the PH of the mouth were also observed after using *Q. infectoria*, as it was found that PH value is close to neutral and within the normal range for all patients.

According to results were due to the fact that *Q. infectoria* contain large amounts of tannin and other compounds that constrict vessels and tissues and are effective as an anti-inflammatory for retention of gum tissue there for we recommend used for treatment.

Keyword: *Gingivitis, Oral pathophysiology, Q. infectoria, Saliva, anti-inflammatory*

Introduction

Oral mucosa essentially goes about as a barrier against the external harmful environments. Loss of its barrier function due to diseases or injury will cause significant dysfunction within the oral cavity[1].

The oral mucosa is the soft tissue covering of the oral hole, including the buccal mucosa and the gingivae . It has a wide range of different functions and consists of a distinct layered structure that is similar to the structure and function of skin[2].

Mechanical stress is continuously placed on the oral environment by activities and lead to sudden changes in temperature and pH meaning it must have the option to adjust to change rapidly . Because of these unique physiological features[3], One of the main functions of the oral mucosa is to physically protect the underlying tissues from the mechanical forces, organisms and toxins in the mouth[4] . Keratinised mucosa is tightly bind to the hard palate and gingivae. It represents 25% of all oral mucosa. It supports underlying tissues by resisting the loading forces exerted during mastication[5].

Due to its area at the passage of the stomach related and respiratory lots and its closeness to the teeth, the oral mucosa is exposed to various normal and man-made xenobiotics [6] . The peculiar architecture and absorption characteristics of the oral mucosa, particularly in areas of extreme thinness, coupled with the rich microorganism flora of the mouth, makes the oral mucosa exposed to many change in physiology tissue [7] .

Gum disease is the most widely recognized type of oral infection,, is characterized by inflammation of the soft tissue without evident clinical attachment loss. Studies on gingivitis have been conducted in many parts of the world with people of different ethnic and cultural backgrounds [8] .

The more extended that plaque and tartar remain on your teeth, the more they irritate the gingiva, the part of your gum around the base of your teeth, causing inflammation. In time, your gums become swollen and bleed easily. Tooth decay additionally may result. If not treated, gingivitis can advance to periodontitis and possible tooth loss [9] .

Within this pH scale of alkalinity and acidity, healthy saliva should generally be slightly acidic and fall between a 5.6 and a 7.9 when saliva exceeds or falls below this range, numerous health complications can occur. Consider that the body is mostly involved of water, which is a neutral substance. If the body drops too far out of the semi-neutral zone, which is approximately a pH level of 7.4, the whole chemical balance shifts and this is where problems can create .[10]

In the event that salvia is excessively acidic, which means it drops below 7.0 at that point it causes an oxygen-denied condition that expands the hazard for tooth demineralization, cavities and tooth decay. This risk increases because bacteria thrive in this type of environment. It is also important to note that foods containing sucrose, glucose, lactose, and starches provide food for the bacteria, allowing them to survive and reproduce [11]

Medicinal plants produce biologically active compounds and this is common in most compounds extracted from plants. *Q. infectoria* is one of the most widely used traditional medicines in Asia found in Cyprus, Syria, Turkey and Greece [12] .

Q. infectoria is a small tree with a height of about 2 meters The main constituents of the galls are gallic acid (2–4%), Gallo tannic acid (50–70%), ellagic acid, starch, and sugar Galls in traditional Indian medicine it was used as a toothpaste to treat gum disease and oral cavity [13] . It has also been used to treat internal bleeding, gonorrhea, tonsillitis and menstruation. It also possesses antibacterial, antiviral, pesticidal, fungal, and anti-inflammatory properties .

Q. infectoria is determined as a natural caustic which has antibacterial and antioxidants properties as well as containing several important bioactive compounds such as tannic acid, flavonoids, gallic acid, ellagic acid and others [14] . All of these bioactive constituents are scientifically demonstrated to give many benefits to human kind, particularly as far as pharmacological studies. Hence, due to this reason, a series of research has been conducted to recognize its beneficial effects in pharmaceuticals area [15] .

It has been used since ancient time to treat the inflammatory disease in oriental traditional medications. Additionally, pharmacology tests have demonstrated that the galls of *Q. infectoria* possess astringent, antitremorine, local anesthetic,antiviral, antibacterial and larvicidal [15] .

The aim of this study is to observe the physiological changes and pH of gingivitis patient by using the properties of Quercus infectoria that was used as a topical powder. And Can it be used as an alternative treatment instead of chemical drugs

Materials and Method

Sample Characteristic: Thirty-five case (20 female and 15 male) examinations were performed by single dentist, who were calibrated to the exact procedures for disease diagnosis,

Clinical examination was performed by using periodontal probe and glass of mouth to obtain gingival index (Loe and Silness, 1963) and then analyzed data to see physiological change after using product .

The mean gingival index was used for the assessment of severity of gingival inflammation in the study sample. Slight gingivitis was defined as gingival index 0.1-1, moderate gingivitis as gingival index 1.1-2.0, and severe gingivitis as gingival index 2.1-3.0.

The effect of *Q. infectoria* on the pH of gingivitis has been diagnoses by used Strips of pH Indicator . saliva was collected for all participants, 5 ml were collected

from each one, and pH values were measured before and after using the product.

Plant Materials:

- The galls of *Q. infectoria* were purchased from the market and used as plant materials for this study
- The product was crushed to small pieces using a sterile pestle and mortar and powdered in an electric grinder.
- The powder was put in plastic containers .
- Patients were diagnosed by a specialist dentist and the cans were then delivered to each of them.
- The topical powder was used by the patient twice a day, in the morning and before bedtime.
- The patients were reviewed at the doctor's clinic after two weeks of using the products and the results were recorded by a personal physician.
- The LD50 was determined using the classical LD50 method of Behrens and Karbers (1953). No side effects have been reported for using this product in the various studies that have worked.

Result

This is clinical study that showed the effect of galls of *Q. infectoria* extracts on people who have gingivitis . Thirty-five people participated in this study. Participants separated for three group G1,20 Female (Table1), G2,10 male (Table2) and G3,5 person as control. all of patient had Physiological problems in the gum tissue like dusky red, swollen, tender gums that bleed easily, especially when you brush your teeth.

The results were observed after using equal quantities of galls of *Q. infectoria* .It showed a significant ($p<0.05$) improvement in the decrease and regression of the inflamed oral tissues for both group.

The progress of gingivitis in group one before and after treatment were 0.7, 0.135, 0.018 and 0.3, 0.125, 0.015 for mean, standard deviation and variance respectively (Figure 1), while progress of gingivitis in group two before and after treatment were 0.678, 0.189,0.03 and 0.291, 0.132, 0.01 for mean, standard deviation and variance respectively (Figure 2).

On the other hand, the salivary pH in gingivitis was more acidic than the control group, pH is maintained near neutrality (6.7-7.3) by saliva In control group while gingivitis was (5.8 -6.8). the Result showed the average pH was 7.24 ± 0.10 after two weeks of using the product. This implies that the physiology of processes taking place within oral tissue is wide ranging and complex. Different levels of pH indicate different chemical environments which may imply that different disease.

Table 1. Comparison of group of female gingivitis before and after treatment with *Q. infectoria*

No	Age	Before	NO	After
1	20	0.9	1	0.5
2	21	0.7	2	0.3
3	24	0.6	3	0.2
4	25	0.7	4	0.2

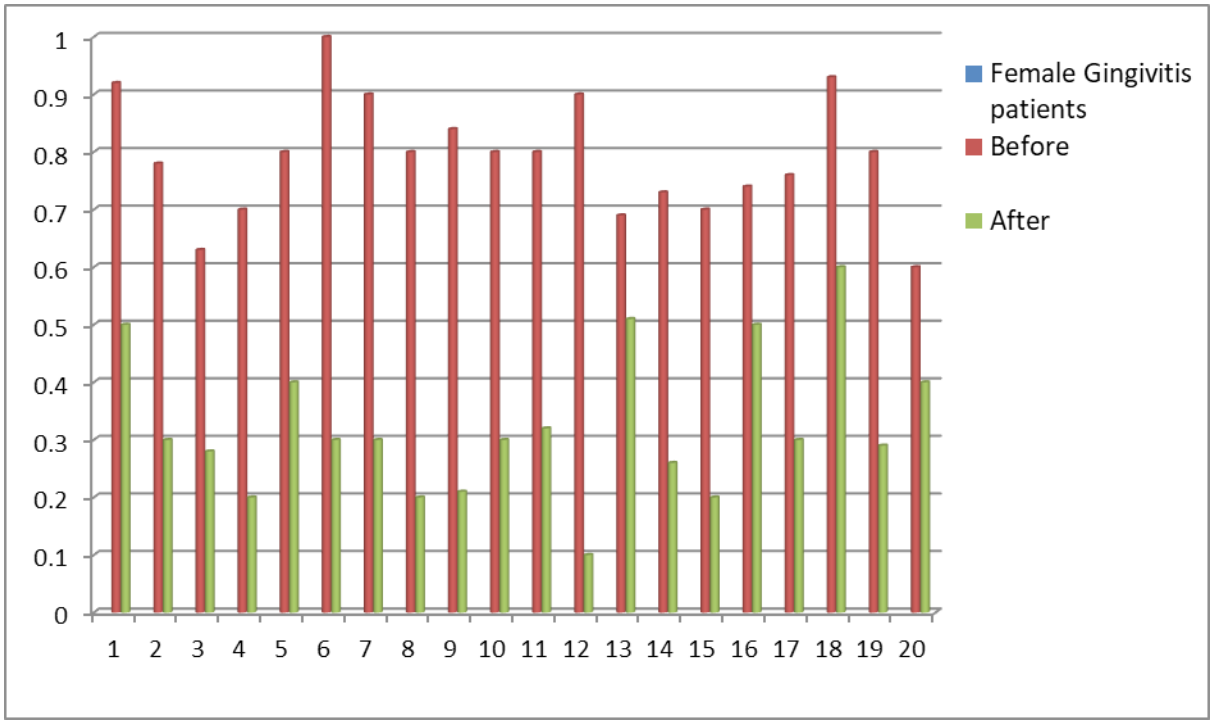

Figure 1. Comparison of group of female gingivitis before and after treatment with *Q. infectoria*

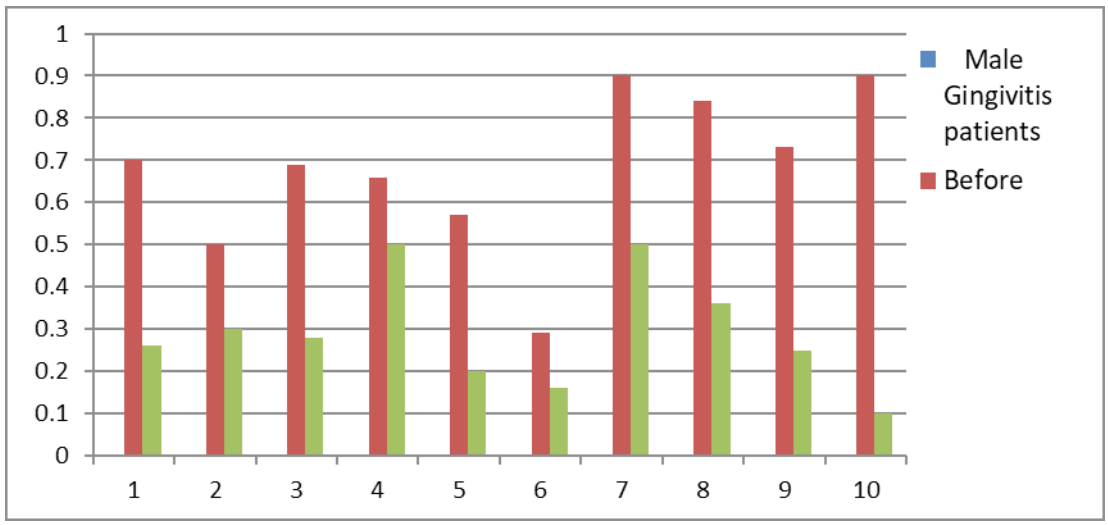

Figure 2. Comparison of group of male gingivitis before and after treatment with *Q. infectoria*

Discussion

This study has proved the high potential in oral physiology during using of galls of *Q. infectoria*, Pharmacologically the galls are claimed to have various biological activities such as astringent effect, anti inflammatory and antibacterial.

We show gingivitis patient have various symptom and manifest like moderate glazing, oedema, redness, and hypertrophy; bleeding on sensing but after two week of used product and According to the diagnosis and continuous careful study of each patient, the results proven high improvement in oral physiology,

Where a significant improvement in healthy gums function was observed, as the color of the gum tissue changed to pale pink while physiologic stippling of gum and tough have a limited sensibility to pain, temperature, and pressure. This improvement in gum tissue is due to *Quercus Infectoria* contain polyphenols which have great reducing power and serve as antioxidant.

An improvement in the oral tissues has also been observed for gingivitis patient suffering from severe inflammation this is due to one of the main reasons that cause gingivitis by infection of bacteria, fungi or viruses which make form plaque that can cling to the teeth which lead to irritate the gums, causing them to become inflamed. The inflamed gums bleed and swell. It is these bleeding and swollen gums that we recognize as gingivitis, Therefore, *Q. infectoria* have a great effect for treating gingivitis, due to their being a good antibacterial and antiviral.

The main constituents found in the galls of Q. infectoria are tannin (50-70%) and small amount of free gallic acid and ellagic acid there for possess pleiotropic therapeutic activities, with particular efficacy against inflammatory diseases,Different formulations can be made in form of gels, ointments, mouthinses and powder to be effectively used for the treatment of gingival diseases.

The resting pH of the oral cavity is between 5 and 9, it is also known to vary widely depending on a number of factors. A change in pH level was seen in severe gingival inflammation.

As the difference in the degree of pH of the mouth depends on the type of food, physiological processes and stress. also various Studies shown growth of microorganisms that effect on PH like P. gingivalis grows at a pH of 6.5-7.0, P. intermedia grows at a pH of 5.0-7.0 and F. nucleatum grows at a pH of 5.5-7.0. 5, 6.

The results showed a significant improvement in the acidity of the mouth and its transformation into neutral, as a result of the use of Q. infectoria, which regression and reduced gingivitis and removed the factors that lead to increased acidity in the mouth.

Conclusion

These results shows a significant change after using herbal product in gingivitis patients, also the salivary pH shows improvement acidity in oral saliva .Therefore, we recommend using this Q. infectoria as an alternative treatments instead of drugs, as an improvement in oral and gum function has been observed without any side effect.

Conflict of Interests: Nil.

Relations between Interlukin-6 and Some Biochemical Parameters in Diabetic Foot Syndrome

Raid M.H. Al-Salih[1], Zeena M. Ali[2]

[1]Prof., [2]Researcher, University of Thi-Qar–College of Science–Department of Chemistry

Abstract

The aim of this study is to predict the incidence of diabetic foot syndrome in type 2 diabetic patients by measuring some parameters (IL-6, FBS, MDA, CP, BMI). Samples were obtained from (75) type II diabetic patients with and without diabetic complications (diabetic foot and diabetic neuropathy), as well as (25) healthy controls as a control group. They were divided into four groups: Group A (the control group):- It included (25) healthy individuals aged between (35-70 years). Group B (Diabetics type II without complications):- Includes (25) patients, their ages range (35-70 years). Group C (diabetic patients with diabetic neuropathy):- It included (25) patients whose ages ranged from (35-70 years). Group D (diabetic patients with diabetic foot syndrome): - Included (25) patients whose ages ranged from (35-70 years). The results showed a significant increase in the levels of (IL-6, FBS, MDA, CP) in all groups of type II diabetes patients with and without complications compared to the control group ($P \leq 0.05$). There was a significant increase in the parameters measured in the group of diabetic patients with type II diabetic foot syndrome (DF) compared to the group of diabetic patients with type II disease Diabetic neuropathy (DN), and the results also showed a significant increase in group DN compared to group of type II diabetic patients (DM) ($P \leq 0.05$). Our study show Interleukin-6 values, as well as oxidative stress, could predict the future incidence of diabetic foot syndrome.

Keywords: *Diabetic foot syndrome, Diabetes mellitus type 2, Diabetic neuropathy, FBG, IL-6, and oxidative stress.*

Introduction

Diabetes mellitus (DM) describes a group of metabolic disorders characterized by high blood glucose levels. People with diabetes have an increased risk of developing a number of serious life-threatening health problems resulting in higher medical care costs, reduced quality of life, and increased mortality[(1)]. The global diabetes prevalence in 2019 is estimated to be 9.3% (463 million people), rising to 10.2% (578 million) by 2030 and 10.9% (700 million) by 2045. The prevalence is higher in urban (10.8%) than rural (7.2%) areas, and in high-income (10.4%) than lowincome countries (4.0%). One in two (50.1%) people living with diabetes do not know that they have diabetes[(2)]. Chronic Diabetic Complications Microvascular complications include:

Retinopathy, Diabetic Neuropathy, Diabetic Nephropathy, Diabetic foot[(3)]. Between 13% and 26% of diabetics report painful chronic polyneuropathy. About 50% of patients with diabetes mellitus develop symptomatic peripheral neuropathy within 25 years of disease onset.

Sensory neuropathy is the primary cause of more than 60% of diabetic foot ulcers. Diabetic peripheral neuropathy is a microvascular complication of diabetes mellitus and in type 2 diabetes, not only hyperglycemia but also other metabolic alterations and persistent inflammatory status due to adiposity play a major role in axon injury[(4)]. Diabetic foot is one of the most feared complications of diabetes mellitus. Diabetes and its complications as foot ulcers may develop as a result

e-mail: raidstry@gmail.com

of polyneuropathy, ischaemic causes, or as a result of all[5]. Hyperglycemia causes tissue injury leading to vascular damage through generation of free radicals and their effect on endothelium in diabetics. oxidative stress plays an important role in the development of Cardio Vascular Diseases (CVD) and diabetes by imbalance of ROS production, and has close relationship with inflammation. It was observed that the lipid peroxidation are increased in patients with MS and it is directly related with the development of atherosclerosis together with establishment of pro-inflammatory state[6,7]. Also, diabetes can be regarded as a pro-oxidant state caused by increased lipid oxidation[8]. Hyperglycemia generates reactive oxygen species (ROS), which in turn cause damage to the cells in many ways. Damage to the cells ultimately results in secondary complications in diabetes mellitus[9].

Oxidative stress induced by reactive oxygen species (ROS), which results from hyperglycemia measured with (FBG), which are the first parameters that give the indication of diabetes[10]. Diabetes is characterized by hyperglycemia along with biochemical changes to glucose and lipid peroxidation. Several studies have evaluated free radical and antioxidant-induced lipid oxidation in diabetics[11,12]. Some complications of diabetes are associated with increased free radical-induced lipid peroxidation activity and accumulation of lipid peroxidation products[13]. Abnormally high levels of oxidation and a simultaneous decrease in antioxidant defense mechanisms can damage cellular organelles and lead to oxidative stress[14]. Under normal physiological conditions, there is a critical balance in the generation of oxygen free radicals and the antioxidant defense systems that organisms use to deactivate and protect themselves against free radical toxicity[15]. An imbalance of oxidative/antioxidant balance creates a condition known as oxidative stress. It is well known that oxidative stress is a component of molecular and cellular tissue damage mechanisms in a broad spectrum of human diseases[16]. Interleukin-6 (IL-6), a major cytokine mediator of the acute-phase response, which stimulates acute-phase protein production in the liver and has diabetogenic actions . The highest levels of acute-phase markers and IL-6 were found in those patients with most features of the insulin resistance syndrome (metabolic syndrome X: glucose intolerance, hypertriglyceridemia, low levels of serum high-density lipoprotein cholesterol, [central] obesity, accelerated atherosclerosis, and hypertension)[17]. Through the review, you present from such a series situation view we design this study to evaluate the level of Interleukin-6 as an inflammatory agent, and we see the possible relationship between interleukin levels and levels of (FBG), (BMI) and oxidative stress.

Patients and Method

Design of Study

The study is conducted at the Diabetes and Endocrinology Center in Thi-Qar and in the biochemistry laboratory in college of science, at the period between (November, 2019) to (May,2020)**.** It included (100) cases, (25) control and (75) patients. There were (100) male and female subjects, control and diabetic of type 2 with and without complication diabetic aged (35-70) years were included in this study. They divided into four groups as the following:-

Group A (Control): Included fifty (25) healthy subjects aged (35-70).

Group B (Diabetes type 2): Included (25) patients with diabetes mellitus type 2 aged (35-70).

Group C (Diabetes Type 2 with nerupathy) Included (25) patients with metabolic syndrome aged (35-70).

Group D (Diabetes Type 2 with diabetic foot syndrome) Included(25) patients with diabetic foot syndrome aged(35-70)

Collection of Blood Sample:

After overnight fasting for about 8 hr, (8 mL) of venous Blood samples were collected between 8:00 and 10:00 am from type 2 diabetic patients and controls then divided into the following:

- (2ml) of blood sample was taken to measure ESR.

- (3 ml)of the blood sample was transferred to tubes containing EDTA (Ethylene diamine tetra acetic acid) and used for HbA1c, CRP, hsCRP estimation.

- (3ml) were transferred to a plain tube and allowed to clot at room temperature to get serum by putting it in empty disposable tubes and centrifuged to separate it at 3000 rotor per minute (rpm) for 10 min, the serum samples were separated and stored at (- 20˚C) for later measurement biochemical parameters, unless used immediately.

Determination of Biochemical Parameters

Interleukin 6 (IL-6): Enzyme Linked Immunosorbent Assay (ELISA) technique was used to measure, serum levels of Interlukine-6 (IL-6 ELISA Kit Dublin, Ireland), in diabetic patients with & without complication diabetes type2 and control group[18,19]

Fasting Blood Glucose (FBG): Glucose was determined after enzymatic oxidation in the presence of glucose oxidase . The hydrogen peroxide formed reacts under catalysis of peroxidase, with phenol and 4-aminophenazone to form a red-violet quinoneimine dye as indicator[20].

Ceruloplasmin (Cp): Serum Cp concentration was measured by the method of[21]. It is based on the ceruloplasmin-catalyzed oxidation of colorless para-phenylene diamine (PPD) to blue-violet oxidize form. The reaction is followed photometrically and the blank value is determined after inhibition of the enzyme with sodium azide[22].

Lipid Peroxidation Marker (Serum MDA): Lipid peroxidation was determined by using the thiobarbituric acid method. MDA concentrations were calculated, using the molar extinction coefficient of MDA (ƐMDA) equal to 1.56 x105 mol-1. cm-1[23]

Statistical Analysis: The statistical analysis proceeded in all groups of study, descriptive statistics analyzed by using one-way analysis of variance (ANOVA) were performed using mean and standard deviations (SDs) with least significant difference (LSD) test for continuous variables (p value ≥0.05) was considered to be significant. All analyses were performed with the Statistical Package for the Social Sciences SPSS for Windows (version 23.0, SPSS Inc, Chicago, III).

Results and Discussions

Clinical and Characteristic Features of the Studied Groups: There are 100 case studies included in this study, with a difference between the groups of type 2 diabetes patients and the health control group in each of them (IL-6,FBG), oxidative stress (MDA,CP), and without difference in each (age, gender, and body mass index).

Interleukin 6 (IL-6): Table (1) shows the statistically significant increase in the levels of (IL-6) in patient groups compared to the control group (P≤0.05), and there is a significant increase in group (DF) compared to groups (DN) and (DM), and also a slight difference was found between group (DN) and group (DM)(P≤0.05). The results of this study agree with A previous study like[24-26].

The most important factor in the development of foot ulcer is peripheral neuropathy. Diabetic peripheral neuropathy is one of the most serious complications of type 2 diabetes mellitus (T2DM) that decreases the quality of life of T2DM patients[27]. T2DM is a metabolic pro-inflammatory disorder characterized by chronic hyperglycemia and increased levels of circulating cytokines suggesting a causal role of inflammation in its etiology. Interleukin (IL)-6, is an important proinflammatory cytokine, that plays a potential pathological role in Diabetic foot disorder. .Proinflammatory cytokines are involved in the pathogenesis of Diabetic foot disorder. Interleukin-6 (IL-6) plays an important role in the inflammatory and autoimmune processes[28].

IL-6 levels are closely related to insulin resistance in type 2 diabetes patients and its complications[29]. IL-6 level is associated with slow flow/microvascular dysfunction[30]. Local levels of inflammatory mediators are associated in the uncontrolled type 2 diabetic patients[31].Type 2 diabetes has been identified as an immune disease that leads to weak insulin signals and selective destruction of insulin-producing beta cells in which cytokines play an important role[32] as well as this study[33] showed higher values of (IL-6) for patients with type II diabetes compared to the control group. And it was proven through the study that (IL-6) reduces insulin sensitivity in the body[34] and thus the concentration of (IL-6) independently predicts the future risks of developing type 2 diabetes and its complications[35] On the other hand, we know that type II diabetes is associated with an mainly with an increase in the waist circumference clinically, and people who suffer from obesity fat tissue represents 50% of the body weight and is the first part of the immune system, as well as the (IL-6) secreted from many tissues, including fat tissue[36] and this explains for us a difference in levels The (IL-6) between study groups according to different body mass index.

Fasting Blood Glucose Concentration: Table (1) shows a significant increase in the concentration of (FBG) in all patient groups compared to the healthy group (P≤0.05). We observed a significant increase in

the concentration of (FBG) in group (DF) and (DN) compared to group (DM) (P≤0.05). This result is consistent with the results of the study[37].

The fasting blood glucose level, which is measured after a fast of 8 hours, is the most commonly used indication of overall glucose homeostasis, largely because of disturbing events. A persistent elevation in blood glucose leads to glucose toxicity, which contributes to cell dysfunction and the pathology grouped together as complications of diabetes[38]. Glucose can be transported from the intestines or liver to other tissues in the body via the bloodstream. Long-term hyperglycemia causes many health problems including heart disease, cancer,eye, kidney, and nerve damage[39].There is a significant increase in the concentration of (FBG) in group (DF) and (DN) because all patients suffering from diabetic foot and neuropathy are patients with type 2 diabetes and obese and their period of diabetes has exceeded 10 years or more. Self-management (controlling the fasting blood sugar level) of diabetes is an essential element to prevent or mitigate complications of diabetes, as[40] it was stated that (FBG) levels increased in diabetic foot patients compared to diabetic patients, because the chronic elevation (FBG) leads to diabetic neuropathy. Which is the gateway to diabetic foot syndrome, as revealed in this study[37]. There is a positive correlation between IL-6 and FBG levels in each of DF(r = 0.29), DN (r= 0.33) and DM (r = 0.21) as shown in figure(1).

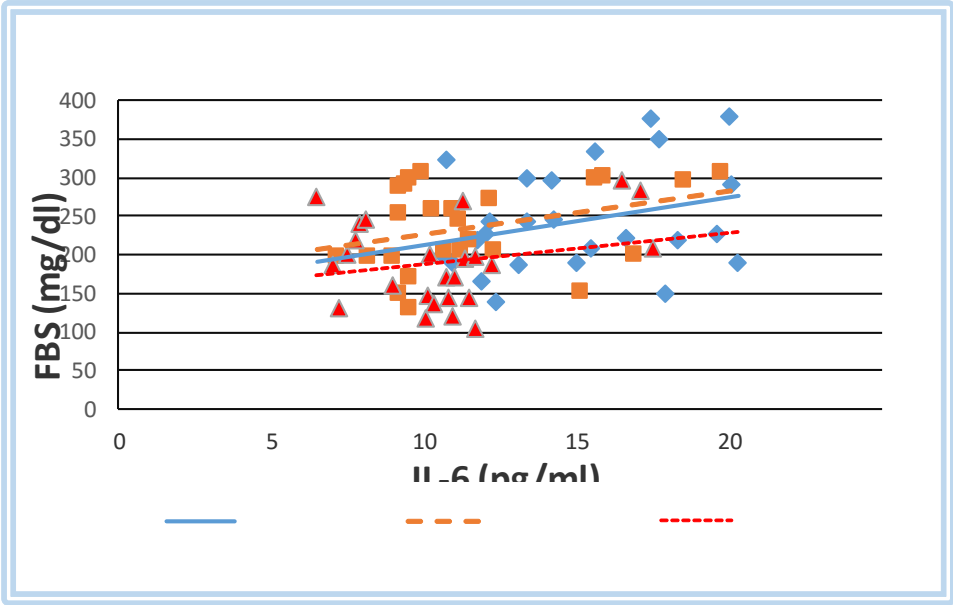

Fig (1): Correlation between IL-6 and FBG

Body mass index (BMI): In all groups, we observed a general increase in BMI due to obesity, but the results for all age groups showed an increase in BMI in all patient groups compared to the control group (p≤0.05). Table (1) show increase simple significance in group DF compared to DN and DM (P≤0.05). These results are consistent with the results of[41]. Obesity is one of the variables that can be changed to reduce the possibility of foot ulceration, and this is especially important because patients who suffer from diabetic foot ulcers often suffer from obesity. Therefore, weight reduction helps relieve pressure on the feet, and also reduces the incidence of diabetic neuropathy. Thus, mitigating the potential strong effect of BMI through appropriate dietary and metabolic control measures the complications of type 2 diabetes in general and of morbidity and the presentation of diabetes in particular[41]. There is a positive correlation between IL-6 and BMI levels in each of DF (r =0.37), DN (r= 0.19) and DM (r = 0.19) as shown in figure(2).

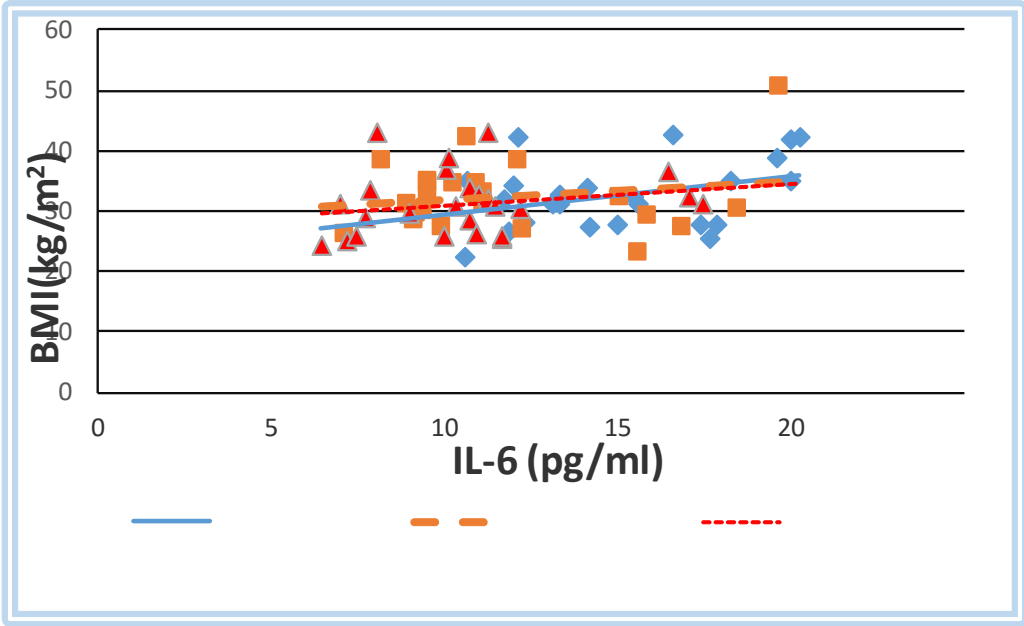

Fig (2): Correlation between IL-6 and BMI

Serum Malondialdehyde (MDA) Concentration: The table (1) shows a statistically significant significant increase in the concentration of (MDA) in all patient groups compared to the control group (P≤0.05). We noticed a significant increase in the concentration of (MDA) in group (DF) and (DN) compared to group (DM) (P≤0.05). We did not notice a statistically significant significant difference between Both groups (DF) and (DN)(P≤0.05). However, we found slight significant differences in the serum concentration between groups (DF) and (DN) .. The results of this study were consistent with the results of a study such[42].

Oxidized lipids have a signaling function in pathological situations, are proinflammatory agonists and contribute to neuronal death under conditions in which membrane lipid peroxidation occurs[43]. Results indicate that lipid peroxidation has a role in the pathogenesis of several such as inflammatory[44].A level of MDA indicates the degree of lipid oxidation resulting from the oxidative degradation of polyunsaturated fatty acids due to increased production of free radicals and impaired antioxidant defenses. Excess fat during each oxidation process may damage various body tissues[45]. Elevated levels of (MDA) may indicate oxidative stress associated with disease activity and its treatment. Diabetic neuropathy may arise from a combination of nerve and microvascular deficits. Oxidative stress can greatly contribute to these deficiencies and may be a direct result of hyperglycemia. Short postprandial peaks in plasma glucose are sufficient to generate the oxidative stress of hyperglycemia. In contrast, acute glucose deprivation also induces apoptosis of peripheral neurons through a mechanism that at least partially involves oxidative stress[46]. Treatments like antioxidants that target oxidative stress are the best solution to control blood glucose levels and thus prevent neuropathy as well as other complications of diabetes[47]. There is a positive correlation between IL-6 and MDA levels in each of DF (r =0.15), DN (r= 0.11) and DM (r = 0.23) as shown in figure(3).

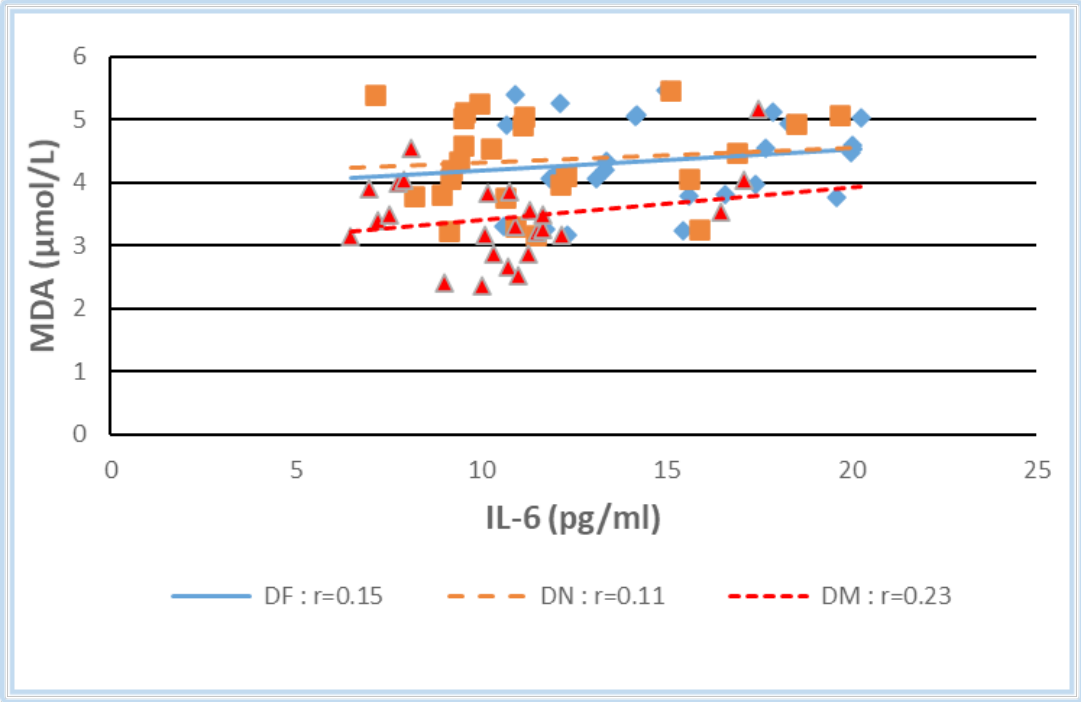

Fig (3): Correlation between IL-6 and MDA

Serum Ceruloplasmin (Cp) Concentration: The table (1) indicates a significant increase in the concentration of (CP) for all groups of patients compared with the control group (P≤0.05). There was a statistically significant increase in group (DF) compared to group (DM) (P≤0.05). We did not notice significant differences in groups (DN). When compared with the two groups (DF) and (DM) (P≤0.05), the results of this study were identical to that of[48].CP plays a role in many biological functions including copper transport, coagulation, angiogenesis, feroxidase activity, and defense against oxidative stress[49]. Coagulation and angiogenesis have a role in diabetes complications. The antioxidant properties of CP are attributed to its ability to inhibit lipid oxidation, scavenge superoxide, and isolate free copper ions[49,50] .CP a protein with specific domains capable of facilitating cellular energy production and preventing the formation of oxygen radicals, and its role in iron metabolism[51]. When there is an abnormality in secretion CP, the excess iron is deposited in the liver, pancreas, and retina, leading to cirrhosis and endocrine abnormalities such as diabetes and vision loss respectively[52,53]. The mechanism behind the positive association between ceruloplasmin levels and the development of diabetic complications is largely unknown. One plausible explanation is that ceruloplasmin might act as a pro-oxidant under conditions of increased oxidative stress, such as in type 2 diabetes mellitus[53]. Although ceruloplasmin possesses antioxidant properties due to its ferroxidase activity, increased generation of ROS disrupts the binding of copper from ceruloplasmin[54]. Ceruloplasmin is an acute phase reactant,and the serum concentration increases during inflammation, infection, and trauma largely as the result of increased gene transcription in hepatocytes mediated bythe inflammatory cytokines[55]. This explains the positive relationship between levels of (CRP,ESR and HS-CRP) that appeared in our study and (CP), as well as the positive correlation between it and (IL-6). There is a positive correlation between IL-6 and CP levels in each of DF (r =0.33), DN (r= 0.52) and DM (r = 0.26) as shown in figure (4).

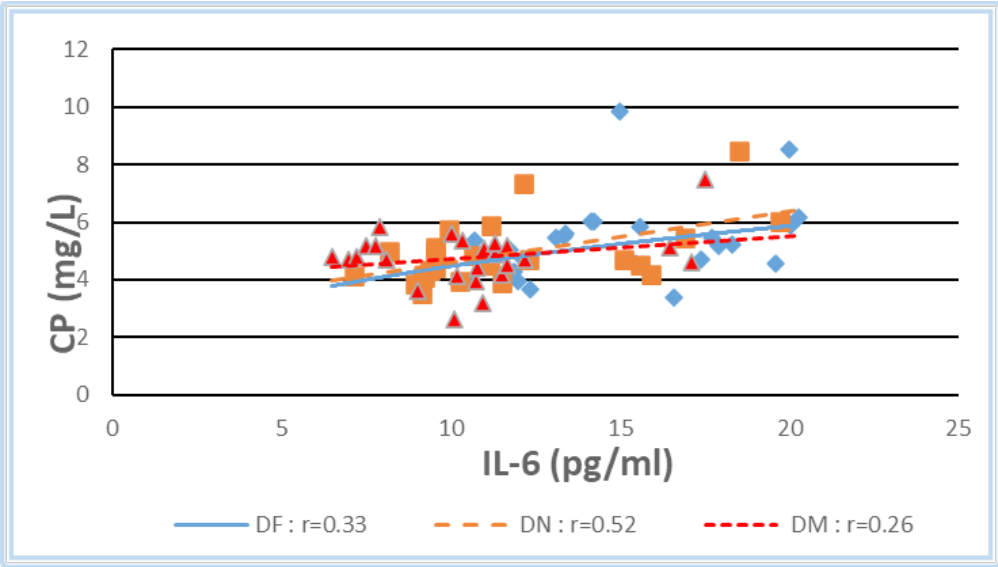

Fig (4): Correlation between IL-6 and CP.

Table 1: Characteristic data for all studied groups.

Parameter	Groups	N	Mean	Std. Deviation
IL_6 (pg/ml)	Control	25	8.89^{c}	1.02

Conclusions

There are oxidative stress and a disturbance in the balance of oxidants and antioxidants in diabetic foot syndrome, neuropathy, and diabetes, which are associated with high levels of glucose. Diabetes and its complications can be controlled by correcting this disorder. IL-6 Positive correlation with (FBG,MDA,CP,BMI).

Ethical Clearance and financial support: Lastly the ethical approval for this study was issued by the ethical commettee of college of science of Thi-Qar university. Moreover there was a financial support from college of science in Thi-Qar university.

Abstract

The outbreak of (COVID-19) has created a global health crisis that has had a deep impact on the way we perceive our world and our everyday lives. This survey was helpful to know the impact of neck pain and leisure activity during lockdown of Female IT workers while remaining at work, and to analyse psycho-social effect on neck pain.

Methodology: Female office workers with neck pain (n = 60) completed a survey about impact of their neck pain and leisure activities. Consequences of neck pain were evaluated with questions on self-reported impact on work and leisure activity. Responses to survey questions were analysed using descriptive analyses.

Result: The point prevalence of NP was significantly related to age, gender, health status, job satisfaction, and length of employment.

Conclusions: The findings provide evidence that the impact on work and leisure was substantial.

Keywords: *Neck Pain, Office Employee, Prevalence, Risk Factors, Consequence, Quality of Life.*

Introduction

Neck pain is very common in the society, particularly in office workers. Neck pain related disability has health and economic impact both at individual and community level. Community based studies worldwide reported annual prevalence of neck pain ranging from 15 to 44%. [1] Globally one-year prevalence of neck pain related disability has been reported ranging from 7%[2] to 11%.[1]Prevalence of neck pain among office workers is higher than in the general community.[3] Globally, one-year prevalence of neck pain among administrative workers has been reported between 15% [4] to 34.4%.[5]

It is considered as a major public health problem, both in terms of health and overall well-being of the person and the society[6-8]. It has imposed relatively high direct and indirect costs, and may affect the quality of life and working condition of patients[6,9,10]. Among occupational groups, office workers, especially intensive computer users, are at high risk for developing Neck Pain[11-18]. Prolonged use of computers during daily work activities and recreation is often cited as a cause of neck pain.

The term work-related neck pain is employed in this research;"computer" refers to desktop and laptop or notebook personal computers, video display units, and video display terminals, to include the use of keyboards and pointing devices (i.e., mice, trackballs).

By defining the pain, "pain is associated with tissue injury and an capability to identify pain sensations.''[19]. This pain and disability is due to the pressure of socioeconomic problems, especially reimbursement to which involves blow injuries[20]. Cervical pain involving skull and neck zone was the outcome of mechanical syndromes, shock, as well as provocative degenerative diseases[21]. This pain occurring from constant postures was defines i''Nonspecific Neck Pain.''[22]. The continuous usage of computers, with wrong posture and sit with rounded shoulders be able to interrupt the normal

lodortic curve of neck that can lead towards muscular discrepancy and therefore neck pain.[23]. Continuous work ion computers and constant load on para spinal neck muscles lead to stretch weakness and pain[24]. Electromyographic studies revealed that the muscles of neck like upper trapezius and cervical erector spinal muscle (CES) had constant loading throughout typing and mouse use.[25]

Increasing computer-based tasks at the workplace may cause poor working postures and repetitive movements, especially in head and neck regions [26]. Different studies have demonstrated that office workers were at high risk of developing Neck Pain, yet, they reported different prevalence rates [26-28].

A number of studies have been carried out to investigate the association between neck pain and occupation. Larsman et al. [29] reported that 70% of medical secretaries had job-related neck pain. For academic staff in Hong Kong, the one-year prevalence of neck pain has been reported as 62%.[30] A high prevalence and incidence of neck and shoulder pain (work-related diseases) is present in the working population, especially in computer-based employment.[31,32]

In general, the percentage of neck pain among women appears to be higher than that in men,[33] and their excursion of head retraction and protrusion is than men in a normal situation.[34]

In an epidemiological study by Jensen et al., carried out on office workers, 53% female workers of call centers reported having NP [26].

Neck pain was more common in female computer operators. It was more common in middle class computer operators as compared to others. 67.3% of computers operators of localized neck and 32.7% complained of radiating neck pain. Neck pain occurred in computer operators due to wrong posture. It reduced the performance of computer operators..

Those persons who work more than two hours on computers are more likely to develop postural neck pain and other musculoskeletal problems at neck region.[35] Greater than 50% of the computer operators have pain in neck, shoulder, arms, wrists and fingers.[36] In one study, 285 of the over-all Dutch employed people worked on pain in the neck, shoulder arms, hands or wrists in the earlier twelve months of employment.[37]

The etiology of work-related neck pain disorders (NPD) seems to be multidimensional is associated with physical and psychosocial factors [38]. A number of factors, including individual factors (e.g. gender and age)[28,39,40], and work related factors (e.g repetitive work, prolonged sitting, and static posture), Work-related psychosocial factors, such as interpersonal associations at work, funds, and finances appear to play a major role on the occurrence of NP [38, 41, 42].

Computer users had symptoms of discomfort in posture, headaches, discomforts in the neck and shoulder due to pain.[43] Computer worker had been related with poor posture and musculoskeletal neck and upper extremity pain.[44] Prevelance of the complaints that had been identified to increase risk of neck pain in computer operators were, reduce in work location ergonomic, employment duration, continuous sitting in front of computer wrong body biomechanics and work station [45] Rationale of this study was to spread awareness about neck pain in computer operators and to determine the prevalence of neck pain in computers users.

The outbreak of the novel corona virus (COVID-19) and the subsequent work-from-home imperatives and lockdown led to significant economic disruptions around the world. For despite being at home all day, remote workers in the the time of corona virus face key challenges that can affect engagement, satisfaction, productivity and mental health. Effects of the pandemic on employees mental health cannot be ignored.Work related muscular-skeletal disorders of the neck are major problem among employees who spend a great deal of time using laptop. Today, a large number of people use laptop for work and recreation, taking up a great deal of their time each day. Such survey would help me to knowing the impact of neck pain and leisure activity during lockdown of female IT workers while remaining at work. No clinical sample, would be collected or the study.This research focused on neck pain in female IT workers as females consistently demonstrate an increased prevalence of neck disorders and usually over-reported in the office worker population. Consequences of neck pain were evaluated with questions on self-reported impact on work and leisure-activity. Responses to survey questions were analyzed using descriptive analyses.

The purpose of our study were: (a) to investigate the prevalence of neck pain and leisure activities among Indian female IT-workers who is currently doing work

from during epidemic period and the impact of work from home on neck pain (b) to analyse psycho-social effect on neck pain and the ratio between these two variables.

Research Hypothesis: There will be significant relation of Impact of Neck pain and Psycho-social effects during Work from Home among Indian Female-IT workers during Epidemic period

Null Hypothesis: There will be no significant relation of Impact of Neck pain and Psycho-social effects during Work from Home among Indian Female-IT workers during Epidemic period

Methodology

Type of Study: Cross sectional normative study design with non random convenient sampling

Ethical Clearance: Prior to conduct of the study institutional ethical approval & an informed consent in writing were obtained from all the participants

Sample Size: 60 participants

Inclusion Criteria: Participants were included in the study if they were normal healthy individuals within the age range of 25-45 years.

Exclusion Criteria:

Maligancy

History of central or peripheral nervous system disorders

Medical diagnosis of systemic, muscular or connective tissue

History of significant injury to neck or upper thoracic region

History of thoracic or cervical spine surgery

Headaches within the last years that resulted in limitation of daily activity

The general questionnaire contained demographic characteristics and background data such as gender, age, height, weight and marital status. The specific questionnaire included questions the existence and duration of neck pain, working posture and duration (for example sitting or positions during work), duration of working on the laptop, the prevalence of NP, and possible risk factors for NP in Female IT- worker's along with the consequences. The validity and reliability of the questionnaires were evidenced. To detect the rate of NP prevalence,six month during epidemics period, work-from-home, prevalence were recorded. The definition of NP was stated in the questionnaire as pain, ache, or discomfort in the area between the occiput and third thoracic vertebra, and between the medial borders of the scapula. A drawing demarcating of the anatomical area was provided in the questionnaire.

Result Analysis

The results showed that during the pandemic period, prevalence of neck Mild to Moderate. Elongated working hours on the computer, taking a prolonged sitting position, overtime, and static postures were the most irritating factors, respectively ($P < 0.001$).

Pie Chart: The result of this study supports that 60 people who are doing work from home 6-12 hour or more then 12 hours least suffering from discomfort and pain in neck,in this study we are finding that people doing work from home 23% people said it increase the stress level, 33% people said it increase work, 11% uncomfortable, 33% comfortable.

Figure 1: It shows the result of work load and stress level,number of people who are doing work from home at least 6-12 hours in a day.

Demographic data analysis: Data processing and analysis was done with graph Pad's website includes the portion of manual graph Pad Prism (window version 8pro) the pie-chart and t-test analysis were used for statistical correlation. The t score is a ratio between the difference between two groups and the difference within the groups. Our small t-score denotes that the groups are similar. $AP > 0.05$ was considered not statistically significant.

P value and statistical significance: The two-tailed P value equals 0.9825 By conventional criteria, this difference is considered to be not statistically significant.

Confidence interval: The mean of Group One minus Group Two equals -0.33 95% confidence interval of this difference: From -39.97 to 39.30 **Intermediate values used in calculations:** t = 0.0234 df = 4 standard error of difference = 14.275

Discussion

This study identified that the severity of neck pain in female IT workers is mild to moderate but that it has negative impact on their work and leisure time activity.

Immediate prevalence of NP was significantly related to female gender. Our study supports previous studies, indicating that NP was a more common complaint among female office employees than male[1,28,30,46]. Wijnhoven et al., in their study, also showed that prevalence rates of musculoskeletal pain were higher for females than males[47].

The general questionnaire contained demographic characteristics and background data such as gender, age, height, weight, and marital status. The specific questionnaire included questions regarding the existence and duration of neck pain, working posture and its duration (for example sitting or standing positions during work), duration of working on the computer, the prevalence of NP, and possible risk factors for NP in office worker's population along with the consequences. The validity and reliability of the questionnaires were evidenced [48].

Ariens et al. [41] also demonstrated that sitting for more than 95% of the working time could enhance the risk of NP. Other studies also confirmed our results and indicated that longer time spent on the computer and improper work conditions may contribute to the development of NP among office workers[47,49].

Our study revealed certain work-related determinants, such as working hours on the computer, prolonged sitting, and forward flexion posture during working, which were the most common factors that enhanced the risk of developing NP among office employees[47].

Conclusion

Thus, my research work has proved that there was a non-significant relation of Impact of Neck pain and Psycho-social effects during work from Home among Indian Female-IT workers during Epidemic period. Some protective strategies such as having a break during hours and performing regular daily exercises were found as useful protective factors to reduce the incidence of NP in office employees.

Abstract

Introduction: Music captures attention, triggers a wide range of emotions, regulates mood and arousal, increases work output, induces states of higher functioning, reduces inhibitions and encourages rhythmic movement. Music has ergo-genic effect as well.

Aim: To evaluate the comparison between classical symphony music and self selected music on muscular endurance levels in young obese males.

Materials and Method: BMI assessment was performed for all participants and the 30 individuals falling under obese category were recruited in the study (BMI ›30 Kg/m^2). The participants were asked to listen to classical symphony music 15 min for 20 days, the muscle endurance test was done by Mosso's ergography and hand dynamometry. After a month the same participants were recalled. The participants were asked to listen to any music of their choice and were grouped under self-selected music. Muscle endurance test was done by hand dynamometry and Mosso's ergography method. Both the values of muscle endurance were compared by using independent paired t test and SPSS software statistical assessment tools were used.

Result: After using self-selected music the muscle endurance significantly increased using hand dynamometry ($p<0.005$) and Mosso's ergography ($p<0.05$).

Conclusion: There may be an improved functioning of neural system due to the influence music. Therefore, music may be used as an additional aid for obese individuals to maintain their skeletal muscle endurance during any physical activity and aerobic exercise

Keywords: *Physical activity, Music, Mosso's ergography, Hand dynamometry.*

Introduction

Obesity is one of most neglected public health problems. Exercising helps to improve body composition and decrease body fat and body weight**(1).** Nowadays it has become a big concern for the youth of today's generation. Accumulation of fat has been classified as mild overweight (excess fat of 20% to 40%), moderate (41% to 100% overweight), and severe (over 100% overweight)(2). It exposes the person to make health risk conditions like sudden death, diabetes of type 2, cardiovascular diseases, sleeplessness, depression and osteoarthritis. It can be a genetic problem or a disorder that is caused due to unhealthy lifestyle habits. Obesity results in sudden disturbance in physical activity as well as emotional disturbance and also a important cause for chronic health problems**(2).** Music is an ergogenic aid. The common positive outcomes when combining music

and exercise appear to be decreased ratings of perceived exertion, increased performance measures, improved mood and increased arousal [3].

Karageorghis has indicated that music is used to alter psychomotor arousal and thus can act either act as a stimulant or sedative. Music reduces a performer's attention therefore the person gets diverted from sensations of fatigue and tiredness and enhances the positive dimensions of mood like happiness, vigor and tempers anger, depression, tension**[4].** Music plays a significant role in emotion, raises spirits, regulates mood**[5],** evokes memories, increases work output and also induces states of higher functioning and reduces inhibitions. In sports science, there is evidence of a positive effect of music on grip strength and performances in other physical activities and other endurance **[6]** thus, music is a powerful key. Lack of sufficient physical activity is a significant factor for obesity. If there is a positive relationship between music and exercise performance (e.g., duration, intensity) the music could help to increase exercise adherence/reduce exercise dropout[7].

The preferred music may facilitate focus on the music or other external stimuli rather than the discomforts that often accompany strenuous exercise. Thus, music also has the capability to evoke pleasant associations, possibly masking unpleasant stimuli or serve as a distraction to internal feelings associated with pain and discomfort [8]. There are studies explaining the differences in slow beat and fast beat music on physical activity but there no research comparing the different types of music.

Listening to music during strength workouts has become a very common practice. Listening to music induced a significant increase of strength endurance performance and no effects on maximal strength [8]. Musical preference reflects the level of arousal needed to perform certain tasks [9]. Specifically, when doing physically demanding work or exercise, choosing inspiring music that the person preferably enjoys is a worthy strategy to follow [10]. A study has tested the effects of fast, energizing music and slow, relaxing music played prior to handgrip dynamometer performance [11]. Slow asynchronous music (< 110 bpm) is generally inappropriate for exercise or training contexts unless used to limit effort exertion or as an auditory backdrop for warm-up/cool-down activities. It has also been proven that there was a positive-linear relationship between exercise heart rate and music-tempo preference[12,13].

Therefore, the present study was conducted to compare the effect of classical symphony (<110 bpm) and self-selected music on muscle endurance. The goal of the present study was to examine which music (self-selected and classical symphony) influences the level of exercise intensity and duration.

Materials and Method

The cross sectional study was started after getting approval by institutional review board. Thirty one resistance-trained medical students were randomly selected and exposed to classical symphony music and self-selected music . The sample size was calculated based on the study by Bartolomei S et al [14]. After getting informed consent the study was carried out from April 2019 to July 2019. The study was conducted in Research lab, department of physiology, Saveetha medical college. The research lab was maintained with zero noise disturbances during the study.

The undergraduate students were identified from Saveetha Medical College aged 18 – 24years. Alcoholics, smokers, subjects with history of diabetes, hypertension and any student with musculoskeletal disorders were excluded. The procedures and benefits of the study were explained to the subjects, before starting each procedure. In this study only male participants were recruited as male has increased muscle mass compared to female. BMI assessment was done. The individuals falling under the obese (›30 Kg/m^2) category were recruited in the study.

Phase I: During phase I classical symphony music was shared to the participants in MP4 format (<110 bpm) prior to the study period. The music selected by the participants were left to their own choice. There was no particular intensity or frequency to choose self- selected music. Participants were asked to listen to classical symphony music for a period of 15 min for 20 days using headphones with closed eyes in a closed room to avoid external deviation. Participants were allowed to listen to the respective music anytime during these days. They were asked to perform hand grip test and Mosso′s Ergography after listening to the music on 20th day [15]. Endurance values were noted.

Phase II: The same participants were reassessed after a month and during this one month resting period the participants were allowed to have normal routine

life and not to listen to classical symphony music. They were asked to listen to self-selected music for period of 15 minutes for 20 days using headphones with closed eyes. On the 20th day the subjects were made to take muscle endurance test, using handgrip dynamometry & Mosso's ergography The tests were done in the research lab, Physiology department and monitored keenly by the investigator in the research lab. The values of muscle endurance by classical symphony music and self-selected music recorded on 20th day of each group were compared among obese male subjects using independent paired T- test.

Mosso′s Ergography test (joule): Subject was made to sit comfortably and asked to insert the index and ring finger into the tube holders and to lift the load by maximal contraction of middle finger until the muscle undergo fatigue. For every 30 sec, 500gms of weight were added. Work done was recorded as graph. Using mosso's ergography, formula used to calculate work done was W = F × S. W= work done, [where F = load in kg, S = sum of the vertical amplitude] in each ergogram

Hand grip test (kg): Proper instructions were given to the subjects: arm should touch lateral side of the body, the forearm should keep in 90^o then place the hand dynamometer in the participant's hand and request the participant to squeeze to his maximum, the needle will automatically record the force (in Kg).

Statistical Analysis: The results for Hand grip test and Mosso's ergography in obese individuals were compared before and after music using the independent samples T – test. Statistical significance was set at $p < 0.05$ using SPSS software version 26.0 .

Result

The mean age of the participants was 19.58 ± 2.0 years. Their mean BMI (Kg/m^2) was 33.4 ± 1.94.

Table 1: Hand Dynamometry: Comparison between Classical symphony music and Self selected music

Parameter	Mean±SD	P –value
Classical symphony music	29.83±2.63	0.021
Self selected music	47.27±4.09	

Table 1 and 2 indicates the values resulted in Hand dynamometer ($p<0.021$) and Mosso's ergography (0.003) respectively. These results clearly show that the work done improved after listening to self-selected music compared to classical symphony music.

Table 2: Mosso's Ergography: Comparison between Classical symphony music and Self-selected music

Parameter	Mean±SD	P –value
Classical symphony music	239.2±34.39	0.003
Self-selected music	330.35±20.75	

Discussion

The present study sought to examine the effects of different kinds of music on the exercise performance on muscle endurance in young obesity male subjects. Specifically, two different types of music were examined: self-selected (SSM) music, and classical (CSM) music. Many authors have indicated that overweight and obesity, expressed by the Body Mass Index (BMI), negatively influence the level of endurance-strength abilities.[4,16,17]

Survey-based data revealed that musical rhythm has a generic stimulative effect on the human organism irrespective of any synchronisation. Hence, in addition to activating few neural structures of brain in a periodic way in order to promote rhythmical movement, music may also cause significant stimulation of those parts of the brain that regulates arousal, namely the limbic and reticular activating systems [17]. Previous research suggests that exercise performance and duration can be influenced for at least two reasons: i) It is possible that the self-selected music provides higher levels of state motivation, thereby increasing exercise performance and endurance in the SSM as opposed to the CM conditions. ii) Listening to motivational music can help the exerciser experience more dissociative thoughts, taking the focus off of the potential discomfort of exercise and internal cues (e.g., self-talk).[18]

Several neural mechanisms may explain the ergogenic impact of music on short- term maximal exercise[19,20]. The present have used two method to measure muscle endurance in the young male subjects hand dynamometry and Mosso's ergography. Like a previous study, using mosso's ergography, subjects were asked to lift from low weight (500gms) to high weight (4000gms) by the middle finger maximal contraction until the subjects gets fatigue[21]. Some studies suggest that the introduction of music has a psychobiological impact on the exerciser demonstrated by changes in perceived muscle endurance [22].

The amount of physical activity performed overall, as well as the physiological response to the exercise, increased with exercise duration, in order to improve the benefits of exercise [23,24]. The present study also indicated that self-selected music has showed significant increase in muscle endurance. Energy and tiredness are often cited as reasons for why people don't exercise. However, exercise has a positive impact on both dimensions of affect. The present study showed significant increase in energy immediately following exercise.

There are numerous evidences to suggest that music, particularly high tempo, can have a positive impact on sporting performance particularly on muscular exercises. However, this has primarily been demonstrated in endurance based exercise rather than fine motor control activities [25-27]. It is interesting to note that performances were greatest in the present study when listening to self-selected music.

Negative aspects of affect, such as high levels of stress and tension, are often associated with an overall lack of well-being, decreasing feelings of tension and stress is an important aspect of regulating affect and mood disorders by listening music [28]. A study has demonstrated increased performance during an explosive exercise and an altered mood state when listening to self-selected music [5]. Therefore, listening to SSM might be beneficial for acute power performance. The current results showed significant changes in feelings of stress, tensions especially muscle endurance performance.

Limitations: The study population was chosen in a random manner and there are chances of bias. Only two types of music were compared to see the effect of muscle endurance. The work could be further extended with various types of music. The individual differences within the group and group differences were not done. The music intensity and frequency was not exactly fixed as they were asked to listen to self-selected music. The study can be further extended to compare the effect of degree of music on muscle endurance.

Conclusion

In light of this study finding, music can be used as an additional aid for obese individuals to improve their skeletal muscle endurance during any physical activity. As well as the music helps to change mood out & stress etc. Our research confirmed also the self selected music is the best one when compared to classical symphony music.

Ethical Clearance: The study was conducted after getting approval from institutional review board (SMC/IEC/2018/11/253)

Factors Affecting Romantic Relationship Satisfaction of University Students

Kyu Eun Lee[1], Hae Kyung Chang[2]

[1]Professor, Department of Nursing, Catholic Kwandong University, Republic of Korea,
[2]Professor, Department of Nursing, Hanseo University, Republic of Korea

Abstract

Background/Objectives: The purpose of this study was to identify the factors affecting romantic relationship satisfaction of university students.

Method/Statistical analysis: This study was conducted with 187 students from four universities in cities and provinces nationwide. Data were collected from September to October 2019 using a self-administered questionnaire. Collected data were analyzed through the stepwise regression analysis using the SPSS statistics program.

Findings: The final regression model showed that self-esteem, anxiety attachment, and avoidance attachment were significant predictors related to romantic relationship satisfaction in university students and explained 34.7% of the variance in romantic relationship satisfaction.

Improvements/Applications: The university student period is a time to form an adult attachment, thereby preparing for a happy marriage in the future by increasing the romantic relationship satisfaction. Therefore, it is necessary to develop and apply the educational programs that can increase self-esteem and positive heterosexual relationship for university students.

Keywords: *University students, sexual attachment, sexual attitude, self-esteem, romantic relationship satisfaction.*

Introduction

The time in university is a transitional stage from adolescence to adulthood[1], and it can be seen in the three main area of identity exploration: love, work, and worldviews which is the late period of adolescence and early period adulthood[2]. In Korea, many young people begin to date only after entering university[3]. A satisfactory experience through the romantic relationship with a partner enhances an individual's psychological health and level of happiness, allows them to feel positive emotions, and influences the development of positive self-concept[4]. Romantic relationship satisfaction refers to the subjective evaluation, attitude, and positive feelings about relationships[5], and attachment is one of key factors related to relationship satisfaction[6].

Adult attachment is the result of a process in which the attachment target shifts from the primary caregiver to friends and lovers as an individual enters into adulthood[7]. For university students in the emerging adulthood, who are in the process of forming adult attachment, the experience of healthy romantic relationship is important in itself. In particular, individuals with stable attachment in relationships with partners have displayed positive characteristics such as confidence, happiness, and constructive approaches toward relationship conflicts, while individuals with high levels of attachment anxiety

Hae Kyung Chang
Professor, Department of Nursing, Hanseo University, Republic of Korea
e-mail: hkchang@hanseo.ac.kr

and avoidance showed negative characteristics such as discomfort, jealousy, etc., in their relationships[7,8]. Therefore, in order for unmarried men and women to maintain a satisfactory relationship with the opposite sex, the sexual aspect must be considered, and for this, an individual's attitude toward sex is important.

Sexual attitude is one's own cognitive perspective on an individual's sexual aspect, is formed through sexual behaviors, and enables individuals to determine current and future sexual behavior based on it[9]. Positive sexual attitudes not only affect personality maturity, but also premarital and post marital sex life [10].

Self-esteem, meanwhile, is a key factor in determining an individual's behavior and adaptation, and it is essential for the healthy sexual function in romantic relationships[11]. Specifically, Lee's study[12], which finds that teenagers with low self-esteem are more exposed to unwanted sex, suggests that self-esteem is related to satisfaction in relationships. Prior studies in Korea frequently show that sexual attitude affects satisfaction in relationships, but the direction of the influence is different. Although the results are inconsistent, it is clear that sexual attitude is correlated with relationship satisfaction[13]. In addition, there are studies on adult attachment and satisfaction with romantic relationship, but there is a only of handful of research on the mechanism. Moreover, there is no research on an integrated approach to the factors affecting the satisfaction of relationships among university students. Therefore, this study aims to provide the necessary basic data to establish healthy romantic relationships and appropriate sexual attitudes of university students by identifying the determinants in relationship satisfaction of university students using variables of various aspects.

Method

Subjects: The subjects of this study were students of universities located in four cities and provinces in Korea and were convenient-sampled to male and female university students with dating experience. Using G*Power 3.12, the sample size of the study was set to be 160, where the median size effect is 0.15, a significance level is 0.05, and the number of predictor variables is 8, to secure 95% of the statistical power for regression analysis. Therefore, in this study, a total of 187 questionnaires were included in the final analysis after distributing the questionnaire to 192 people considering the dropout rate of 20%.

Tools:

Adult Attachment: The Experience in Close Relationship (ECRS), developed by Brennan et al.[14], was used. Adult attachment measurement tools consist of two areas: 18 questions for avoidance attachment and 18 questions for anxiety attachment. The higher the score on a 5-point scale of 36 questions, the higher the avoidance attachment and anxiety attachment. In this study, Cronbach's α were found to be 0.74 (avoidance attachment), 0.87 (anxiety attachment), and 0.83 overall

Sexual Attitude: The sexual attitude measurement tool developed by Woo[10] was used. The tool was comprised of 35 questions with a 5-point scale. A higher score means a more open sex attitude, and a lower score means a more conservative sex attitude. Cronbach's α in this study was found to be 0.74

Self-esteem: The self-esteem measurement tool developed by Rosenberg[15] was used. The self-esteem measurement tool consists of 10 questions with a 5-point scale. A higher score means a higher degree of self-esteem. Cronbach's α in this study was found to be 0.82

Romantic relationship satisfaction: The romantic relationship satisfaction measurement tool developed by Lee[16] was used. The tool consists of 41 questions with a 5-point scale. A higher score means higher romantic relationship satisfaction. Cronbach's α in this study was found to be 0.92.

Data collection: For the data collection, universities located in four different regions across the country from September 9 to October 31, 2019 were randomly selected. Through a research assistant at each local university, the purpose and method of the study were explained to the study subjects, and written consents from the subjects who exhibited voluntary participation were received. The research assistants explained that the collected data would not be disclosed or used for any purpose other than research, that the subject's personal information would be kept confidential and guarantee anonymity, and that the subject could stop participating in the research at any time if desired. The data were collected using structured questionnaires and it took 10~15 minutes to complete the questionnaire.

Ethical Considerations: This study was conducted after receiving research approval from the Institutional Review Board (IRB) of University C to project the subjects in prior to conducting the study (IRB No: CKU-19-01-0207)

Data Analysis Method: The collected data were processed by computer statistics using SPSS/WIN 22.0 program. Descriptive statistics for the general characteristics and variables of the subjects were obtained. The difference in Romantic relationship satisfaction level was determined according to general characteristics t-test, ANOVA, and post-test Scheffé test. The correlation between the Romantic relationship satisfaction and the variables was analyzed by Pearson's correlation coefficient. In addition, in order to identify factors affecting the Romantic relationship satisfaction, it was analyzed by stepwise multiple regression after multicollinearity diagnosis.

Result

General characteristics of subjects: Mean age of the subjects was 21.03(±2.06) years old and 20 to 29 years old group was the most among these with 134 persons (71.7%). The distributions of the gender were 95 male (50.8%), 92 female (49.2%). There were 1st 55(29.4%), 2nd 41(21.9%), 3rd 39(20.9%) and 4th 52(27.8%) in the Grade. Residence was living alone 82(43.9%), dormitory 72(38.5%) (Table 1).

Table 1. General Characteristics and Difference in Degree of Romantic Relationship Satisfaction according to General Characteristics

Characteristics	Categories	n(%) M±SD	Romantic relationship satisfaction			
			M±SD	t/F	p	Scheffé
Age	Teens (10's)	53(28.3)	2.60±0.52	0.09	.929	
	Twenties (20's)	134(71.7)	2.59±0.52			
		21.03±2.06				
Gender	Male	95(50.8)	2.53±0.54	-1.73	.085	
	Female	92(49.2)	2.66±0.50			
Grade	1st	55(29.4)	2.56±0.49	2.42	.067	
	2nd	41(21.9)	2.76±0.45			
	3rd	39(20.9)	2.62±0.55			
	4th	52(27.8)	2.48±0.56			
Residence	Home	31(16.6)	2.60±0.47	0.38	.767	
	Dormitory	72(38.5)	2.64±0.48			
	Living alone	82(43.9)	2.56±0.55			
	Etc.	2(1.1)	2.44±1.28			

Descriptive statistics of the study variables: Attachment averaged 2.78(±058). In addition, the average sexual attitude was 3.04 (±0.36), and the self-esteem was 3.66 (±0.62) (Table 2).

Table 2. Descriptive Statistics of the Study Variables

Variables	Mean	SD	Min	Max
Avoidance attachment	2.73	0.44	1.33	3.72
Anxiety attachment	2.78	0.58	1.28	4.67
Sexual attitude	3.04	0.36	1.46	4.43
Self-esteem	3.66	0.62	1.30	4.90
Romantic relationship satisfaction	2.59	0.52	1.27	4.24

Difference in degree of romantic relationship satisfaction according to general characteristics: The degree of romantic relationship satisfaction was non-significantly different according to general characteristics (Table 1).

Correlation between romantic relationship satisfaction and variables: The degree of romantic relationship satisfaction of the subjects was positively correlated with self-esteem (r=0.53, p<0.001) and negatively correlated with avoidance attachment (r=-0.40, p<0.001), anxiety attachment (r=-0.42, p=0.008), and sex attitude (r=-0.19, p=0.008). In other words, a higher degree of self-esteem, lower avoidance and anxiety attachment, and more conservative sexual attitudes all led to higher satisfaction in romantic relationships (Table 3).

Table 3. Correlations Coefficient among the Variables

Variables	Avoidance attachment	Anxiety attachment	Sexual attitude	Self-esteem
	r (p)	r (p)	r (p)	r (p)
Romantic relationship satisfaction	-.40 (<.001)	-.42 (<.001)	-.19 (.008)	.53 (<.001)

Influencing factors on romantic relationship satisfaction: As a result of verifying the multicollinearity before performing regression analysis, the variance expansion index (VIF) among the variables is 1.140 to 1.561, which is less than 10, which can be considered free of autocorrelation. In addition, the Durbin-Watson statistic that confirms the independence among the error terms was found to be 1.594, which satisfies the assumption of independence. A total of four independent variables were used to identify the determinants of romantic relationship satisfaction: adult attachment (avoidance attachment and anxiety attachment), sexual attitude, and self-esteem. The stepwise regression analysis results are as follows: self-esteem (β=0.330, p<0.001), anxiety attachment (β=-0.237, p<0.001), and avoidance attachment (β=-0.209, p=0.002). The exploratory power of the three variables 34.7%, and the most influential variable was self-esteem (Table 4).

Table 4. Influencing Factors on Romantic Relationship Satisfaction

Variables	B	β	t	p
Intercept	-2.334		-5.371	<.001
Self-esteem	.275	.330	4.574	<.001
Anxiety Attachment	-.213	-.237	-3.601	<.001
Avoidance Attachment	-.246	-.209	-3.166	.002
F = 33.875, p < .001, Adj R2 =.347				

Discussion

In this study, the romantic relationship satisfaction level of the university students was 2.59 points on a scale within a range from 1 to 5. This score was lower than the average of 3.47 points of the local university students, which was measured with the identical measurement tool[17].

As a result of examining the correlation between university students' romantic relationship satisfaction and their variables, it was found that adult attachment had a negative correlation with romantic relationship satisfaction. This result is consistent with Choi and Kim[17] and Yildiz, Cokamay, and Artar[18]. In general, the two dimensions of adult attachment, avoidance attachment and anxiety attachment, are viewed

as unstable attachment, and there tend to be more relationship problems as the degree of adult attachment grows stronger[19].Anxiety attachment in this study had a stronger negative correlation with romantic relationship satisfaction than did avoidance attachment, which is similar to the results in the previous literature[17].

People with high anxiety attachment tend to focus on their stress, reflect on negative thoughts, and emotion-centered coping strategies. On the other hand, those with a high level of avoidance attachment use strategies that cognitively and behaviorally distance themselves from the cause of stress [20].

The university students' sexual attitude and romantic relationship satisfaction were found to have a negative correlation, which was consistent with the prior result of Hendrick, Hendrick, and Reich[21] that more conservative sexual attitude leads to higher romantic relationship satisfaction. Conversely, a study of unmarried men and women with sexual experience reports a significant positive correlation between sexual consciousness and romantic relationship satisfaction[13], showing no consistency in the correlation between sexual attitude and romantic relationship satisfaction. In the future, if one establishes a strategy to maintain a satisfactory relationship by identifying the attitude of individuals, he or she will be able to increase satisfaction on the relationship.

Furthermore, romantic relationship satisfaction is higher in the group with high self-esteem[22], which is consistent with the results of this study. Through these results, one will be able to enhance romantic relationship satisfaction by turning negative sexual attitude into positive sexual attitude when establishing a strategy to maintain a satisfactory romantic relationship.

After analyzing the effects on romantic relationship satisfaction in the study, self-esteem, (β=0.330, $p<0.001$), anxiety attachment (β=-0.237, $p<0.001$), and (β=-0.209, $p=0.002$) explain 34.7% of romantic relationship satisfaction. Among them, self-esteem was the most influential variable on relationship satisfaction. It can be interpreted that those who love themselves and feel valued maintain satisfactory relationships with their partners[23].There are several factors in the characteristics which people with low self-esteem exhibit in relationships. First, they need more acceptance and incorrectly perceive others' attitude. These people believe that they need to live up to the specific standards they have set for themselves or need to have valuable traits to be loved and accepted by important people, so they underestimate the positive attitudes their partners have toward themselves or evaluate less of their partners' attitude[11].If the partner's continued acceptance is suspected, he or she could distance himself or herself from the partner, devalue romantic relationships, be unnecessarily disappointed in them, and end the relationship in dissatisfaction [24].

Anxiety and avoidance attachment, which are forms of unstable attachment among adult attachments, were the second and third factors that explained the relationship satisfaction of the university students. Hazan and Shaver[7] argue that adult attachment is the one of the most well-known variables in predicting relationship satisfaction and is related with romantic relationships in adulthood. Their findings demonstrate that positive emotions as happiness and trust are usually reported in relationships in the case of stable attachment, whereas instable attachment types such as avoidance or anxiety feel a lot of negative emotions such as discomfort or jealousy in relationships.

The overall results suggest that it is necessary for university students, in order to improve the romantic relationship satisfaction, to have a positive and active life attitude toward their own lives so that they can stablish positive sexual attitudes and enhance their self-esteem.

Conclusions

In this study, self-esteem, anxiety attachment, and avoidance attachment were significant predictors that influence university students' romantic relationship satisfaction and the three variables' explanatory power was 34.7%. Based on these results, it is necessary for university students to develop a sense of self-respect and experience the process of exchanging positive feelings with their partners in order to improve their satisfaction with romantic relationships.

This study is meaningful in that it takes account sexual attachment variables, a new concept in nursing, into account to provide nursing intervention to enhance healthy relationship satisfaction of university students.

Non-Invasive Monitoring of Blood Glucose Concentration Based on Insulin Secretion Level Using NIR Spectroscopy for Diabetes Detection

D. Arul Kumar[1], T. Jayanthy[2]

[1]Research Scholar, Department of Electronics and Communication Engineering, Sathyabama Institute of Science and Technology, Chennai, India, [2]Principal, Panimalar Institute of Technology, Chennai, India

Abstract

Diabetes claims millions of lives every year. Diabetes Mellitus is a metabolic disorder that occurs due to the increase in blood sugar level. The blood sugar level control by insulin secreted from pancreas. The diabetes classify as type 1 and type 2 depending on insulin secretion. The type 2 diabetes is more common in people than type 1 diabetes. Traditionally, the blood glucose level estimate with glucometer and blood test. However, the test require invasive blood pricking for blood glucose measurement. The measured blood glucose value also varies due to amount of blood taken for testing, part of blood used for testing, depth of finger pricking, physical activity, stress and underlying illness. Hence, the insulin secretion from pancreas monitor for accurate prediction of blood glucose level. The blood glucose level varies with respect to insulin secretion from pancreas. In this paper, we propose a non-invasive approach to estimate blood glucose accurately through NIR spectroscopy for diabetes control. The NIR spectroscopy signal obtained from pancreas process through Rational Dilation Wavelet Transformto determine the insulin secretion level. The non-invasive NIR spectroscopy method measures glucose level with 90% accuracy compared to lab results.

Keywords: *Type 2 Diabetes, RADWT, NIR spectroscopy, Insulin.*

Introduction

Diabetes mellitus characterizes by the abnormal increase of sugar level in the blood. When the glucose level in the blood increases, it induces the insulin release from the pancreas. Insulin causes fat cells and muscle to remove glucose from the blood and causes the liver to metabolize glucose and thus reduceblood sugar to normal levels. People with diabetes have high levels of blood sugarsince, pancreas does not produce insulin. The diabetic person have minimal count of β-cells in pancreas which secretes low insulin.

The most general forms of diabetes are type 1,type 2 diabetes, and gestational diabetes. The type 1 diabetes is an autoimmune disorderwhere, the body attacks the pancreas making it unable to produce insulin resulting in minimal insulin secretion. Thetype 2 diabetes cause due to factors such as metabolic disorders, age, overweight, obesity, physical inactivity and unhealthy food consumption. The β cell in pancreas produce insufficient insulin coupled with organ resistance to insulin and result in high blood glucose level. The gestational diabetes occurs during pregnancy.

Currently, the blood glucose level control by medication and insulin injection coupled with diet control and physical activity. The blood glucose level determine by blood test or glucometer. The first introduced blood glucose meter was Ames Reflectance Meter. The Ames Reflectance Meter enables diabetic patients to monitor the blood glucose levels themselves. Reflomat is another portable and compact blood glucose meter designed for health care professionals. The Reflomat requires only a small amount of blood to determine blood glucose level. The foresaid meter needs extraction of blood samples through fingertip pricking, ear pricking. The blood glucose monitoring require taking test for up to 4 times every day. Therefore, continuously pricking of finger, ear for blood to determine blood glucose level may cause infection, and calcified nodules. The blood sugar level estimated by glucometer are inaccurate due to damaged blood cells. Further, the frequent skin pricking

is uncomfortable, inconvenient and cause skin irritation. Hence, precise, convenient, safe and comfortable blood glucose measurement method is required.

The blood glucose also measure by non-invasive method. The polarization change is the first introduced non-invasive technique where combination of helium and neon based laser light is coupled to a linear polarizer and the phase matches with the rotation vector is relative to glucose.

Raman Spectroscopy can detect low frequency modes. A Surface Enhanced Raman Spectroscopy (SERS) detects the interaction between glucose molecules and SERS active surface. The monochromatic light on molecule result in photon energy shift. The energy shift of photon is proportional to molecular bond vibration. The molecular vibration have specific Raman spectrum band. The spectrum band featuresvary for different molecules such as glucose.

Fluorescent spectroscopy is an electromagnetic spectroscopy technique that can analyze a sample's fluorescence. Fluorescent Spectroscopy utilizes visible light spectrum, to detect energy emitted at different wavelength from glucose molecule. Near-Infrared (NIR) spectroscopy employs near-infrared light of wavelength 780-2500nm. In NIR spectroscopy, glucose level estimates with respect to the variations in the light intensity. Mid-Infrared (MIR) spectroscopy is developed from NIR spectroscopy that utilizes the near infrared light of wavelength 2500-10000nm. MIR spectroscopy is sharper and does not penetrate through the skin effectively. Absorption spectroscopy in the infrared (IR) region is a significant technique for finding unidentified biological substances in aqueous solutions. The technique is based on the process that every molecule has particular resonant absorption peaks. These peaks are caused by molecule's rotational and vibrational oscillations.

Literature Survey: Non-invasive blood glucose monitoring perform through in vitro and in vivo analysis of Differential Continuous Wave Photo Acoustic Spectroscopy (DCW-PAS). The DCW-PAS approach uses amplitude modulation withdual wavelengths of light to identify glucose concentration level. The analysis compares DCW-PAS evaluations including results from invasive blood glucose sensor evaluations of healthy people's Oral Glucose Tolerance Tests (OGTTs). The blood glucose level estimation from photo-acoustic signal and invasive sensors have good correlation. [1]

The blood glucose level measure with plasmonic sensor made of barium flint glass, gold film andsilicon nitride (Si_3N_4) substrate. The plasmonic sensor rejects infrared wavelength on normal incidence because of coupling between plasmonic wave and incident plane wave. The impact of glucose concentration or ambient refraction analyze for plasmonic structure sensitivity toblood glucose.[2]

A Spoof Surface Plasmon Polariton (SSPP) endfire sensor monitors aqueous glucose solutions and measures on-body glucose. The SSPP endfire sensor radiates an endfire beam into a glucose water solution with minimal effective aperture. At the sensor's CPW port, a set of triangular ground planes suppresses the side-lobes and limit glucose sensing. The SSPP endfire sensor's slow wave nature provides the way for measuring glucose concentrations with enhanced sensitivity. [3]

Non-invasive blood glucose monitoring offers an effective solution to diagnose patients with diabetes the glucose response characterize at low Radio Frequency (RF) signals. The relative permittivity and conductivity of aqueous solutions obtain for various glucose concentrations using an impedance analyzer in the frequency range 1 KHz to 1MHz. Further, the blood impedance measure for glucose monitoring the bio-impedance, measure from forearm during cardiac cycle with polygraph at 1000 Hz. The difference in bio impedance evaluate for cardiac cycle. The influence of blood glucose concentration on bio impedance evaluate to remove tissue influence on blood glucose concentration. [4]

The design of a microwave sensor for non-invasive monitoring of blood glucose concentration is presented. Three distinct microwave resonator structures analyze as suitable candidates. The microwave resonator has an open structure to place patient's finger. The finger's shape and size should fit in the resonator. The variation in blood glucose concentration alters the tissue's dielectric properties and changes the structure's resonant frequency. [5]

A combined millimeter-wave radar system detects various glucose concentration levels of duplicate blood samples made in the laboratory. The mm-wave radarnon-invasively monitors blood glucose of patients with diabetes. The mm-wave radar signal with Discrete Time

Fourier Transform finds various glucose concentrations in hemoglobin samples. [6]

The near infrared spectroscopy non-invasively measures glucose concentration in blood. The infrared light pass through finger and blood glucose concentration evaluate by calculating absorbance through Beer-Lambert law. The infrared absorbance is equivalent to blood glucose concentration and finger thickness. [7]

A sensitive Glucose fringe field Microstrip Line (MLIN), Material under Test (MUT) – glucose as substrate detects concentration of glucose and ports. The electromagnetic field from MLIN interacts with MUT and show variation in $|S_{11}|_{min}$. The glucose concentration estimate by Single variate, multivariate and multivariate estimation with bin correlation algorithm.[8]

An implanted sensor with telemetry system monitors subcutaneous tissue glucose for long term in diabetic patients. The implantable sensor consist of immobilized glucose oxidase membrane, polydimethylsiloxanemembrane, catalase connected to electrochemical oxygen detection and telemetry system for wireless data transmission. [9]

A planar microwave sensor monitors glucose level continuously. The sensor element contains four different hexagonal-shaped complementary split ring resonators (CSRR) resembling honey-cell pattern. The resonator was fabricated on a FR4 dielectric substrate and connected to planar micro strip with dielectric substrate. The CSRRs were connected through microstrip transmission line to a radar system operating at 2.4-2.5 GHz. The combined sensor system achieves a good sensitivity in detecting the glucose levels that dissolves in the blood similar to aqueous solutions.[1A substrate integrated waveguide (SIW) planar sensor's design measured blood glucose concentration non-invasively. The SIW planar sensor's structure resembles traditional band stop filter. The SIW planar sensor, yields a considerable and localized field improvement in the sensing region, the inter-digital arms and the slots on the SIW planar sensor cavity's upper conductor are utilized. Additionally, fingertip is utilized as material under test (MUT) and the effects of finger prints and the finger's displacement are analyzed.[11]

The ZnO based ultrasonic piezoelectric Micro-Electronics Mechanical Systems (MEMS) receiver monitors blood glucose. The radial displacement and the surface of the ultrasonic piezoelectric MEMS receiver produce voltage due to pressure and stress. The voltage vary with respect to blood concentration level. The simulation analysis of glucose data showed agreeable correlation with glucometer reading. [12]

The blood glucose monitor with RF/microwave technology. The RF sensor measure blood glucose level by detecting dielectric changes of blood. The dielectric variation due to glucose causes the sensor frequency to shift below 8Mhz. The frequency shift also occur due to blood layer, skin, fat, pressure and position of finger.[13]

A wearable, minimum invasive autonomous and pseudo-continuous blood glucose monitoring. This wearable micro system design obtains a whole blood sample from a little lanced skin wound utilizing a new micro-actuator based on a shape memory alloy (SMA) and straightly measures the blood glucose level from the blood sample.[14]

A wirelessly powered implantable electrochemical sensor system monitors blood glucosecontinuously. The system was powerby 13.56 MHz inductive link and an ISO 15693 radio frequency identification (RFID) standard for telemetric communication. The sensor system comprises awinding ferrite antenna, a RFID front-end, a 10-bit sigma-delta analog to digital converter (ADC), a long-term glucose sensor, an on-chiptemperature sensor, a potentiostatand a digital baseband for controlling and processing protocol. A high frequency (HF) external readerpowers, commands and configures the sensor system directly. The off-chip support circuitry requiresa glucose micro-sensor and a tuned antenna.[15]

Methodology

The non-invasive technique of diabetes detection is performed by measuring the blood glucose concentration through NIR spectroscopy. The NIR spectroscopy measures blood glucose concentration by evaluating insulin secretion from pancreas. The NIR sensor is placed on the pancreas region.Figure 1 shows the overview of diabetes prediction withreflected infrared from pancreas.

Pancreas is a gland that is six inches long and located in the abdomen. It is flat and pear shaped, surrounded by liver, small intestine, spleen, stomach. The pancreas's endocrine cells produce hormones. Hormones are substances that regulate or control particular functions in the body. Hormones are generally formed in one part of the body and passed through the blood to react on another part of the body. The two important pancreatic

hormones are insulin and glucagon. The endocrine cells such as the islet cells present in the pancreas produce and secrete glucagon and insulin in the blood. Glucagon increases the blood sugar level while insulin lowers the blood sugar level. The two hormones function together to maintain proper blood sugar level. The figure 2 shows the structure of pancreas.

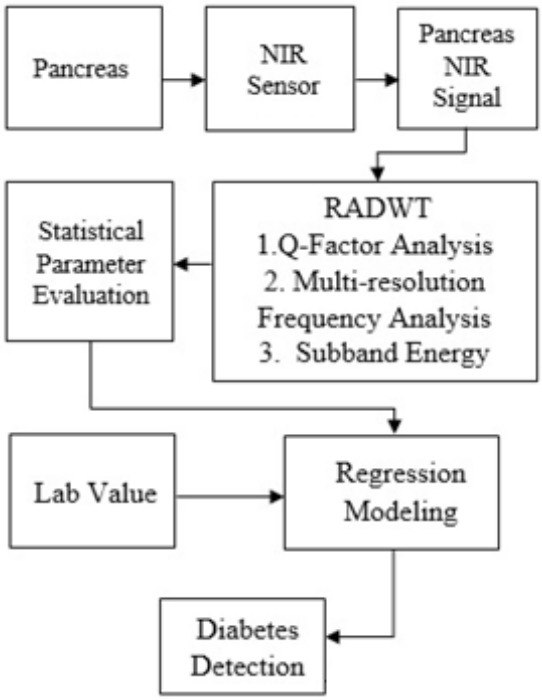

Figure 1. Overview of diabetes detection with NIR through RADWT algorithm.

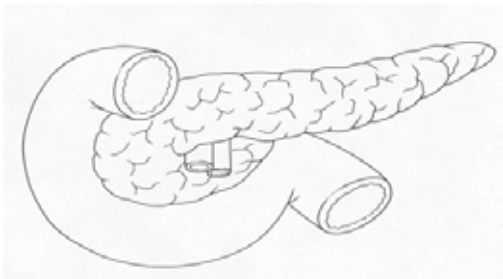

Figure 2. Structure of Pancreas

To find the insulin secretion level from pancreas, NIR spectroscopy is used. NIR spectroscopy is a spectroscopic technique that utilizes the electromagnetic spectrum's from near infrared region. NIR spectroscopy is used in various medical applications such as pulse oximetry, blood sugar level monitoring, neurology and urology. The NIR sensor is placed on the pancreas region as shown in figure 3. The reflected infrared signal from pancreas acquire with data acquisition tool. The infrared signal from pancreas of normal and diabetic person. The pancreas infrared signal obtain for before meal and after meal condition. The acquired infrared signalsprocesses through Rational Dilation Wavelet Transform (RADWT) to determine infrared variation due toinsulin secretion. In RADWT, the Q-factor value change for resolution and subband energy level of pancreas NIR signal.

Figure 3. NIR Diode Placed on the Pancreas Region

Rational Dilation Wavelet Transform (RADWT): The Dyadic Wavelet Transform is an effective transformation tool for sparsely representing the smooth signals and it is a constant Q-factor transform and a critically sampled wavelet transform. However, its frequency resolution is poor and has a low Q-factor. The Dyadic Wavelet Transform is not effective for processing NIR signals with oscillatory nature. Some techniques like Cosine Modulated Filter Banks, Short Time Fourier Transform (STFT), wavelet packets are traditionally used for oscillatory type signals rather than using dyadic wavelet transform. The transforms do not have a constant Q-factor. So an efficient transform with constant and high Q-factor and high frequency resolution is required. Another category of wavelet transforms like overcomplete wavelet transform performs efficiently than critically sampled wavelet transforms like dyadic wavelet transform. Overcomplete wavelet transforms extend an N-point NIR signal to a set of M coefficients with $M>N$. Several overcomplete invertible wavelet transforms such as double density wavelet transform, dual tree complex wavelet transform and undecimated wavelet transform exists. These wavelet transforms achieve over completeness through increasing only the temporal sampling in all frequency bands. The frequency spacing between adjacent frequency bands should be reduced to utilize the overcomplete wavelet transform's redundancy. These overcomplete wavelet transforms are based on rational dilations. The figure 4 represents the Rational Dilation Wavelet Transform (RADWT) where

$H(\omega)$ is high pass filter, $G(\omega)$ is low pass filter, p and q are rational dilation factors and s is redundancy factor.

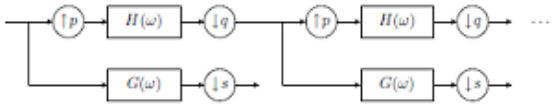

Figure 4. RADWT

The selection of dilation factor close to one, a wavelet can be dilated from scale to scale and multi resolution frequency analysis of the NIR signal can be performed. Additionally, the dilation factors p and q and the redundancy factor s enhance the Q-factor and frequency resolution of the NIR signal. The Q factor of the signal resolution depend on the rational dilation factors q and p. The filter banks of RADWT is shown in figure 5.

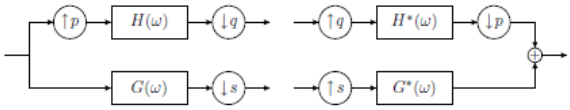

Figure 5. Filter Bank of the proposed RADWT

The perfect reconstruction filters for the filter bank shown in figure 5 is derived. The parameters p, q and s are positive integers that satisfy $1 \leq p < q$ and $p/q + 1/s \geq 1$. The integers p, q are coprime. For perfect reconstruction $p + 1 = q = s$. The only condition for perfect reconstruction filters is

$$\frac{1}{pq}\left|H\left(\frac{\omega}{p}\right)\right|^2 + \frac{1}{s}|G(\omega)|^2 = 1 \text{ for } \omega \in [0,\pi] \quad (1)$$

Finally, the perfect reconstruction filters are given as

$$H(\omega) = \begin{cases} \sqrt{pq} & \omega \in \left[0, \left(1-\frac{1}{s}\right)\frac{\pi}{p}\right) \\ \sqrt{pq}\,\theta\left(\frac{\omega-a}{b}\right) & \omega \in \left[\left(1-\frac{1}{s}\right)\frac{\pi}{p}, \frac{\pi}{q}\right) \\ 0 & \omega \in \left[\frac{\pi}{q}, \pi\right] \end{cases}$$

$$G(\omega) = \begin{cases} 0 & \omega \in \left[0, \left(1-\frac{1}{g}\right)\pi\right) \\ \sqrt{s}\,\theta_c\left(\frac{\omega-pa}{pb}\right) & \omega \in \left[\left(1-\frac{1}{g}\right)\pi, \frac{p}{q}\pi\right) \\ \sqrt{s} & \omega \in \left[\frac{p}{q}\pi, \pi\right] \end{cases} \quad (2)$$

Results and Discussion

The NIR sensor position over pancreas of diabetic person and infrared signal acquire for before meal consumption and after meal consumption. The infrared signal acquired before meal consumption is shown in figure 6.

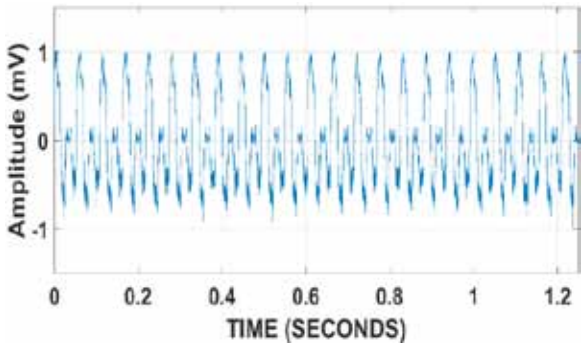

Figure 6. Pancreas NIR signal (Before meal consumption)

The acquired NIR signal decompose up to 11 levels to determine subband signal influenced by pancreas insulin secretion. The NIR signal process through RADWT for multi-resolution frequency analysis. The decomposed subband signal is shown in figure 7.Figure 8 shows the reconstructed subband signal from individual subband.

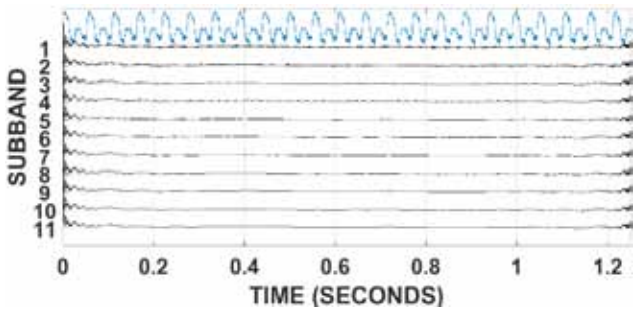

Figure 7. NIR signal decomposition with RADWT (Before meal consumption)

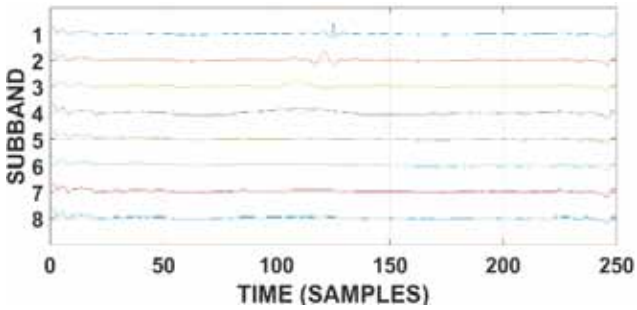

Figure 8. Reconstructed subband signal of the pancreas NIR signal (Before Meal consumption)

The multiresolution analysis evaluate for NIR signal subband energy. The RADWT, decomposes the signal and subband energy evaluate for each subband signal. The subband energy level of the NIR signal before meal consumption is shown in figure 9.

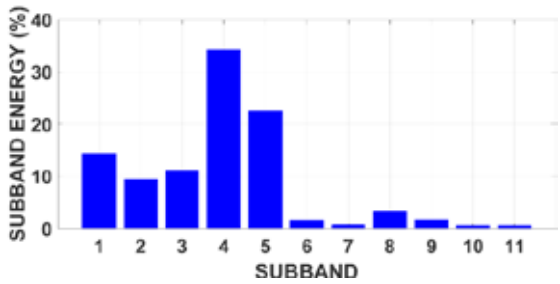

Figure 9. Subband Energy Level of the Pancreas NIR signal (Before meal consumption)

In figure 9 the subband energy level is low due to low insulin secretion from pancreas. The low insulin secretion from pancreas cause high blood glucose level. The subband energy level attains a maximum of 24% at fifth subband.

The pancreas NIR signal was obtained from pancreas with NIR sensor after mealconsumption is shown in figure 10.

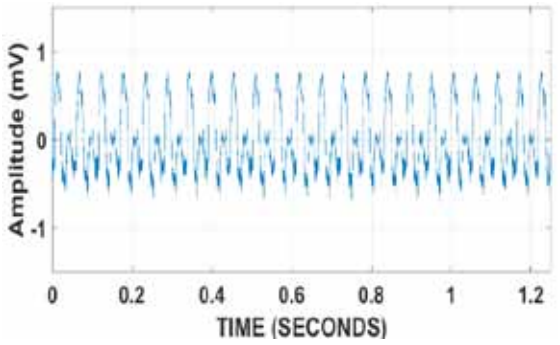

Figure 10. Pancreas NIR signal (After meal consumption)

The decomposed signal with RADWTis shown in figure 11. The subband signal reconstructed with RADWT from individual subband is shown in figure 12. In figure 12, the subband energy increases when the insulin secretion level from pancreas increase.

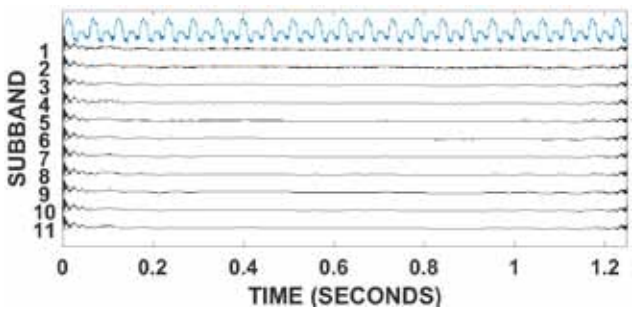

Figure 11. NIR signal decomposition with RADWT (Aftermealconsumption)

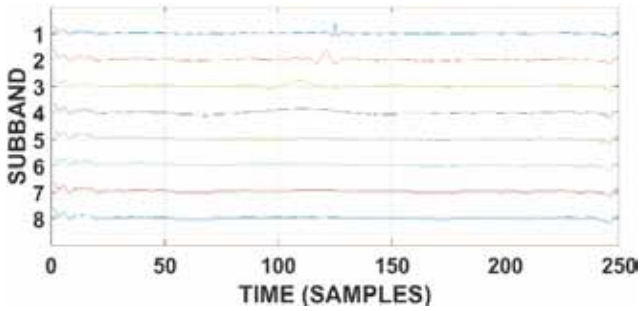

Figure 12. Reconstructed subband signal of the pancreas NIR signal (After meal consumption)

The subband energy level reconstructed NIR signal with RADWT from pancreas after meal consumption is shown in figure 13.

In figure 13, the subband energy level increases due to insulin secretion from pancreas. The subband energy level attains a maximum of 28% for fifth subband. The increase in pancreas insulin secretion lowers blood glucose level.

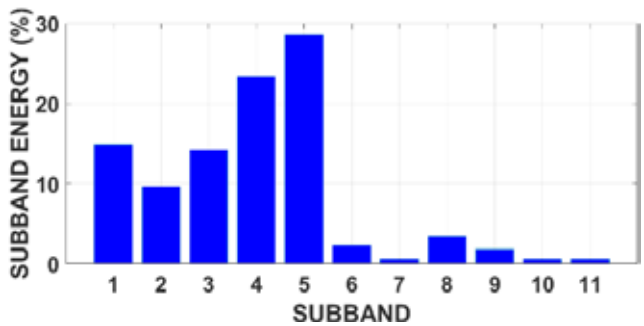

Figure 13. Subband Energy Level of the Pancreas NIR signal (After meal consumption)

The NIR signal from pancreas of non-diabetic person was obtained for before food consumption and after food consumption scenarios. The NIR subband energy variation was similar to diabetic person. However, the subband energy increased to maximum of 35% at fifth subband before food consumption and increased further to 42% after food consumptiondue to high insulin response. The subband energy increased proportional to insulin response from pancreas. The high insulin response from pancreas regulated blood sugar level. The table 1 gives information about subband energy, insulin response and glucometer reading of diabetic and non-diabetic person.

Table 1: NIR signal parameter of diabetic and non-diabetic person.

Parameters	Diabetic person		Nondiabetic person	
	Before meal consumption	After meal consumption	Before meal consumption	After meal consumption
Subband energy	24	28	15	21
Glucometer values	183	240	95	132
Lab results	165	228	90	120

Regression Modeling: The regression modeling is a statistical procedure used to estimate the linear or straight-line relationship that relates two or more variables. The linear relationship represents amount of change in one variable that relates with change in another variable. The regression modeling also evaluate for statistical significance, to check whether the linear relationship emerge by chance or not. The two variable regression model includes two variables such as an independent variable and a dependent variable. The independent variable causes changes in the dependent variable.

Linear Regression: Linear regression model determines relationship between two variables through fitting a linear equation forobserved data. One variable is considered as an explanatory variable, and the other is considered as a dependent variable.

The equation of a linear regression line is of the form

$$Y = a + bX \tag{3}$$

where,

X is the explanatory variable.

Y is the dependent variable.

The slope of line is *b*, and the intercept is *a* (the value of *y* when *x* = 0). The formula for computing intercept *a* and slope *b* is given as

$$a = \frac{(\sum y)(\sum x^2)-(\sum x)(\sum xy)}{n(\sum x^2)-(\sum x)^2}$$
$$b = \frac{n(\sum xy)-(\sum x)(\sum y)}{n(\sum x^2)-(\sum x)^2} \tag{4}$$

The blood glucose level of diabetic person obtain from subband energy and labvalues represent by equation

$$Y = 14.20*X - 159.0 \tag{5}$$

and the blood sugar level of non-diabetic person represent by

$$Y = 6.393*X - 1.357 \tag{6}$$

Conclusion

A non-invasive technique for monitoring blood glucose concentration is presented. The blood glucose level determine with insulin secretion level from pancreas, NIR sensor measures the insulation secretion level in pancreas. The intensity of the NIR light varies according to the insulin secretion level in pancreas. The NIR signal obtained from the pancreas is processed through RADWT to evaluate the insulin level in pancreas. The RADWT subband energy level is relative to insulin secretion from pancreas. The subband energy is low when the insulin secretion level in pancreas is low,before food consumption and the sub band energy level is high when insulin secretion level in pancreas increase after food consumption. The subband energy of NIR signal validates with glucometer measurement results.

Effects of Multidrug-Resistant Organism Infection Control Simulation Program on the Infection Control Fatigue, Job Stress, and Performance of Nurses

Mi Hyang Lee

Associate Professor, Department of Nursing, College of Nursing, Konyang University 158, Gwanjeodong-ro, Seo-gu, Daejeon, South Korea

Abstract

Background: This study was conducted to develop a training program simulating multidrug-resistant organism infection control for nurses and to verify its effectiveness.

Method: This was a randomized, control-group, pretest-posttest design study carried out with a total of thirty-one nurses. A general lecture on theories was provided to the control group, while the developed simulation training program was implemented for the experimental group.

Result: The results showed that the experimental group who received the multidrug-resistant infection control simulation training program recorded higher infection control performance than the control group who received lecture-based training (p=.029). However, there was no statistically significant difference in infection control fatigue and job stress between the two groups.

Conclusion: It was found that the simulation training program is an effective intervention that can improve the performance of infection control. Repeated research on diverse variables is necessary in the future in order to continuously measure the effectiveness of the simulation training program.

Keywords: *MDROs, Fatigue, Job stress, Performance, Simulation training.*

Introduction

Healthcare-associated infections have steadily been on the rise due to a widespread use of invasive treatment method and an increase in multidrug-resistant organisms (MDROs)[1]. Healthcare-associated infections caused by MDROs, in particular, are known to exacerbate the medical condition of patients and even raise mortality,[2] in addition to increasing the hospitalization period and medical costs, thereby causing more financial burden on patients and their families[3].They are problematic even from the viewpoint of healthcare institutions in relation to increased costs from patient isolation, lack of space for isolation and greater workload for the medical staff to control and prevent the spread of infection[4].

Nurses taking part in the treatment of infected patients experience physical and mental burden arising from the difficulties related to wearing personal protective equipment (PPE) and managingpatients[5]. On the other hand, there are patients who believe that the medical staff is to blame for the occurrence of MDROs, which causes the relationship between such patients and the medical staff to rapidly deteriorate, and this in turn further increases mental fatigue for the medical staff[6]. When nurses nursing patients infected with MDROs the more fatigue they will experience due to increased workload such as hand hygiene and wearing PPE, and under these circumstances, they will likely have difficulty concentrating on their job and become more easily distracted, resulting in poorer job performance[7]. Therefore, in order to provide quality nursing services to patients, it is necessary to reduce the infection control fatigue experienced by nurses.

Nurses tend to experience high job stress due to the high demand for professional knowledge and skills, interpersonal conflict with patients, higher nursing quality demanded by patients, and occupational nature in

dealing with human lives[8]. Nurses who are involved in treating a patient with infectious diseases, in particular, experience emotional pain due to the idea that they themselves are responsible for the patient's infection or death and fear that they could become a medium and spread the infection to other patients[9]. The higher the job stress faced by nurses, the more difficult it is for them to provide quality nursing to patients, and it also leads to reduced productivity and work efficiency[10]. Plus,higher job stress leads to a higher chance of a burnout[8], which eventually lead to higher turnover. Therefore, it is necessary to reduce the job stress that may occur when nurses care for patients infected with MDROs.

Nurses were found to experience high stress in relation to professional expertise and PPE among other factors when nursing patients infected with MDROs. According to a study conducted by Lee[11],67.8% of nurses in small- and medium-sized hospitals have received training for MDRO infection control, while 86.1% have had experience in nursing patients with infected with MDROs. In other words, it was found that there were cases in which nurses had to care for patients infected with MDROs without having received any MDRO infection control training, and insufficient knowledge of infection control would likely have increase the level of stress they experienced. Moreover, MDRO infection control training mostly consists of lectures on theoretical knowledge, which makes it is difficult for nurses to apply the knowledge they gain in practice. Simulation training has recently been introduced in the healthcare sector, and it is known to be highly effective in allowing trainees apply the theories they have learned in lectures to clinical performance[12].

Simulation training is a method of training that helps improve the clinical competency of nurses in a safe educational environment where there is no potential harm to patients, and it is a method of training that helps cultivate comprehensive performance capacity suitable for various situations[13]. As for prior studies that examined simulation training for nurses, Lee andAhn[14] reported improved knowledge of emergency situations, clinical performance capacity, and performance confidence, and Cho et al.[1] reported that it helped enhanced the infection control performance of participating nurses.

Accordingly, this study was conducted with the aim of examining the effects of MDRO infection control training on the infection control fatigue, job stress, and performance of nurses.

Study Objectives: The purpose of this study is to determine the effects of MDRO infection control simulation training on infection control fatigue, job stress and performance of nurses. The specific objectives are as follows:

1. Verify the difference in the level of fatigue from infection control before and after MDRO infection control simulation training;
2. Verify the difference in the level of job stress from infection control before and after MDRO infection control simulation training;
3. Verify the difference in the level of infection control performance before and after MDRO infection control simulation training.

Method

Study Design: This was a randomized, control-group, pretest-posttest design study carried out with the application of an MDRO infection control simulation training program to verify its effectiveness.

Participants: The subjects in this study were nurses in a certain region who voluntarily agreed to participate in this study with an understanding of the purpose and procedure of the study. The number of samples required for the study was calculated using the G*power 3.1 program, and the number of samples required for t-test was calculated based on a significance level of .05, group number of 2, effect size of .08, and power of .80. The minimum number of samples for analysis was found to be 26 for the experimental group and 26 for the control group. Due to the outbreak of COVID-19, some of the subjects refused to participate in the study, and ultimately, there were 17 subjects in the experimental group and 14 subjects in the control group.

Measurements:

1. **Fatigue from infection control:** A total of 29 questions were asked based on a 5-point Likert scale, with the highest score indicating the highest level of fatigue. As for the reliability of the tool, Cronbach's alpha was measured to be .94.
2. **Job stress from infection control:** A total of 32 questions were asked based on a 5-point Likert scale, with the highest score indicating the highest level of job stress. Cronbach's alpha was .96.
3. **MDROinfection control performance:** A total of 16 questions were asked based on a 5-point Likert

scale, with the highest score indicating the highest level of MDRO infection control performance. Cronbach's alpha was .92.

Intervention

1. **Preliminary Survey:** Both the control group and the experimental group were asked to fill out a questionnaire on fatigue, job stress, and performance in relation to MDRO infection control without receiving any infection control training. The subjects were not given any information on whether they belonged to the control group or the experimental group.

2. **Intervention**

1. **Experimental Group:** The developed MDRO infection control simulation scenario was administered by a nurse specializing in infection control. One virtual patient, one legal guardian, and one nurse were selected, and three nurses with at least five years of experience or more at the medical institution performed the evaluation based on a checklist.

The scenario consisted of nursing activities routinely performed in the ward, such as administering medication, measuring vital signs, and emptying urine bags for MDRO patients in isolation. The checklist required the evaluators to perform evaluation on the nursing activities before entering the patient room and while in the patient room, use of PPE and hand hygiene practice when leaving the patient room, etc. After the scenario was administered, corrections were made through a 15-minute debriefing process, and manual demonstration training was conducted.

2. **Control Group:** A nurse specializing in infection control gave an hour-long lecture explaining the definition of MDRO, transmission method, and theories related to contact isolation based on a PowerPoint presentation.

3. **Follow-up Survey:** Immediately after the simulation training and lecture-based training, the same questionnaire was distributed to both the experimental group and the control group. After the final questionnaire was completed, simulation training was administered to the control group.

Statistical Analysis: The data collected were analyzed using the SPSS/WIN 21.0 program, based on the following analysis method: The test of homogeneity between the experimental group and the control group was carried out by the Chi-square test, Fisher's exact test, and Mann-Whitney U test depending on the characteristics of the variables. The hypotheses with respect to the MDRO infection control fatigue, job stress, and performance were tested using the Mann-Whitney U test.

Findings:

Characteristics of Test Subjects and Test of Homogeneity: The results of the test of homogeneity according to the general characteristics of the subjects are shown in Table 1. There were no significant differences in age, sex, affiliated department, MDRO infection control training in the past year, or prior experience in nursing an MDRO-infected patient between the control and experimental groups (Table 1). A comparison of infection control fatigue, job stress, and performance between the two groups before the simulation training program showed no significant difference between them (Table 2). As there was no significant difference between the control group and the experimental group, they were deemed homogeneous.

Table 1. General Characteristics of the Experimental and Control Groups (n=31)

Variable	Categories	Cont. (n=14)	Exp. (n=17)	U/χ^2	p
		n(%)	n(%)		
Age		31.71±10.77	34.35±7.28	-.811	.424
Sex	Male	1 (7.1)	3 (17.6)	.754	.607
	Female	13 (92.9)	14 (82.4)		
Affiliated department	Ward	9 (64.3)	10 (58.8)	.097	1.000
	Special department	5 (35.7)	7 (41.2)		

Variable	Categories	Cont. (n=14)	Exp. (n=17)	U/χ^2	p
		n(%)	n(%)		
MDRO infection control training received in the past year	Yes	3 (21.4)	8 (47.1)	2.203	.258
	No	11 (78.6)	9 (52.9)		
Prior experience in nursing an MDRO-infected patient	Yes	10 (71.4)	5 (29.4)	.003	1.000
	No	4 (28.6)	12 (70.6)		

Table 2. Test of Homogeneity Between the Experimental and Control Groups in Dependent Variables (n=31)

Variable		Cont. (n=14)	Exp. (n=17)	U	p
		M±SD	M±SD		
Infection control fatigue	Pre-test	3.37±.53	3.56±.43	116.5	.922
Infection control job stress	Pre-test	3.55±.58	3.66±.57	103.0	.544
Infection control performance	Pre-test	4.15±.44	4.42±.34	72.0	.064

Effects of MDRO Infection Control Simulation Training Program: Hypothesis 1: The hypothesis that the "experimental group receiving simulation training will experience lower infection control fatigue than the control group receiving lecture-based training" was tested, and the results showed no statistically significant difference, with the experimental group recording 3.40±.49 and the control group 3.45±.51 (U=109.5, *p*=.710). Therefore, Hypothesis 1 was not supported.

The hypothesis that the "experimental group receiving simulation training will experience lower infection control job stress than the control group receiving lecture-based training" was tested, and the results showed no statistically significant difference, with the experimental group recording 3.62±.58 and the control group 3.50±.54 (U=92.0, *p*=.297). Therefore, Hypothesis 2 was not supported.

Hypothesis 3: The hypothesis that the "experimental group receiving simulation training will exhibit better infection control performance than the control group receiving lecture-based training" was tested, and the results showed no statistically significant difference, with the experimental group recording 4.60±.32 and the control group 4.18±.54 (U=64.0, *p*=.029). Therefore, Hypothesis 3 was not supported.

	Exp. (n=17)	4.42±.34	4.60±.32	.18±.46		

Discussion

This study was conducted with the aim of developing an MDRO infection control simulation training program and verifying its effectiveness. With homogeneous experimental and control groups, the MDRO infection control simulation training program was administered to the former. The results of verifying the MDRO infection control fatigue showed that it decreased by 0.16 points from 3.56 points to 3.40 points, on average, for the experimental group, while it increased by 0.08 points from 3.37 points to 3.45 points for the control group. However, the difference was not statistically significant. Even in the case of job stress, it decreased by 0.04 points from 3.66 points to 3.62 points, on average, for the experimental group, and it decreased by 0.05 points from 3.55 points to 3.50 points for the control group. The difference was not statistically significant. Although it is difficult to compare the changes in the levels of infection control fatigue and job stress resulting from the simulation training intervention, as there have not been prior studies examining these two variables, it is believed that it would be difficult to directly reduce infection control fatigue and job stress with short-term training. In this study, infection control fatigue and job stress were evaluated immediately after the application of the simulation training program, which is thought to be too short to truly evaluate the effectiveness of the training program on these two variables. It is predicted that it will be better to compare the changes in the infection control fatigue and stress before and after the application of the intervention program while allowing the participating nurses actually apply what they have learned in the clinical setting for some time. Thus, it is suggested that a re-evaluation be performed 4 to 8 weeks after the simulation training program intervention.

The infection control performance was verified after applying the MDRO infection control simulation training program, and the results showed it increased by 0.18 points from 4.42 points to 4.60 points for the experimental group, and it increased by 0.3 points from 4.15 to 4.18 points for the control group. The difference between the two groups was found to be statistically significant. This was similar to the findings reported by Cho et al.[1] that infection control performance was enhanced after simulation training, while there was no difference in the infection control awareness and self-efficacy. The results were similar to the findings reported by Lee and Ahn[14] in regard to their study on nurses.

Simulation training helps trainees synthesize and apply knowledge rather than simply acquiring knowledge[15]. It is believed that the subjects in this study exhibited enhanced performance by affirming and applying the knowledge they had previously learned in theoretical education on MDROs through simulation.

Based on these results, it is believed that it will be effective to use the simulation training method to improve the MDRO infection control performance of nurses. Going forward, it will be necessary to develop various scenarios and repeat this research in order to understand the effects of simulation using a control group. It will also be necessary to evaluate infection control fatigue and job stress 2 to 4 weeks after training in order to evaluate the effectiveness of the simulation training program in an ongoing manner.

Conclusion and Recommendations

In this study, a simulation training program was developed and applied, and the differences in infection control fatigue, job stress, and performance between the experimental group and the control group after the application of the MDRO infection control simulation training program were examined. The results showed that the simulation training program is an effective intervention for improving infection control performance. In order to continuously measure the effectiveness of simulation training in the future, it will be necessary to conduct this research repeatedly on various variables.

Assessment of Breast Cancer Risk by Gail Model in Women of Thi-Qar

Sara OmranIssa[1,2], Zainab H. Farhood[1], Zaman Subhi Madlool[1]

[1]Assistant Lecture at Department of Biology, College of Education for Pure Science, University of Thi-Qar/Iraq, [2]saraom895@gmail.com

Abstract

The aim of current study to assess the high incidence of breast cancer (BC) and the effect of its earlydiagnosis on decreasing morbidity and mortality among Iraqi women. A descriptive cross-sectional study was conducted and data were collected from 106 women in Thi-Qar by a questionnaire consisted of demographic and breast cancer risk (BCR) factors questions. Brest cancer risk was calculated using the BCR Assessment Tool (BCRAT) of the National Cancer Institute's online version (Gail Model).Results: The average age of women was 43.44± 11.3 years. Ten (9.4%) women have first degree relatives who had BC and five of them have more than one. Fifty (45.3%) had their menarche at 12–13 years of age,32 (29.2%) had their first birth at 20-24 year of age. The mean five year BCR for all women was 1.25± 1.46%, and 15 (14.15%) of them had a five year BCR >1.7%. Mean lifetime BCR up to age 90 years was 13.11± 12.76% and 8(7.54%) women had high risk. Based on these findings, it may be suggested that Gail Model for BCR assessment can help healthcare providers in Iraq to estimate an individual's probability of developing BC for early detection and prevention.

Keywords: *Gail model; Breast cancer; Thi–Qar.*

Introduction

Breast cancer is the most common type of cancer in women. It is estimated that about 1.4 million new cases every year all over the world, and this disease accounts for about 25% of all cancer cases in women and is the second most common after lung cancer. This can happen in men, but this is uncommon. The incidence of this disease is much higher in developed countries than in developing countries (IARC, 2010). Incidence is increasing rapidly in many newly industrialized countries due to changing lifestyles in developed countries [1]

In 2010, it was recorded that 721 of the women who underwent a breast examination at the examination center for early detection of breast cancer in Iraq, 143 cases of this disease were diagnosed (19.8%). Although 90.6% of women initially self-discovered these lumps, Another study conducted in 2012 to explore the knowledge, attitudes and practices towards breast cancer in a sample of educated women, revealed that nearly half of the participants had a low knowledge score for this disease (less than 50%). The study indicated that 90% of the participants heard about breast self-examination (BSE), however, we only found only 43% of them practiced this technique[2].

First type assesses the likelihood of BRCA mutations such as the Claus model where all predictions are based only on family history [3] The second type of risk factor used in BC includes the Gail model (GM) and the modified model (GM2) that calculates 5-invasive BCR and lifetime [4]] GM is the most widely used risk prediction mode and the land has been studied, validated and applied in various studies around the world [5-7] So the aim of the current study was to apply GM2 to the Iraqi population and assess whether it could be used to assess BC prediction for women Iraqi women.

Materials and Method

This study is a cross-sectional design and descriptive . The data were collected from 106 women who had applied to Bint Al Huda Hospital in Thi-Qar, a city in southern Iraq. The purpose of the study was explained to each woman and those who refused to participate

were excluded. A total of 106 women in the ages of 35 years and older were included and data were collected between May and Jane 2020.

The questionnaire was used in this study based on the online version of the National Cancer Institute's Breast Cancer Risk Assessment Tool (BCRAT)also known as Gail Model available at (http://www.cancer.gov/bcrisktool/) which has questions about the five-year and lifetime BC risk based onage, age at first live birth, age at menarche, first degree relative numbers with BC, previous breast biopsies with or without atypical hyperplasia, BRCA mutations and woman race[8]

The questionnaire also had additional questions about sociodemographic features such as occupation, education,marital status, family income and husband education level. Unknown BRCA mutations and the white race/ethnicity(Caucasian) variables were used for all the women in this study in estimating their risks[9] For five-year risk assessment, a rate of 1.7% or less was defined as low risk while a rate of 1.7% or more was defined as high risk[4,9] Lifetime risks were classified as usual(<15%), moderate (15–30%), or strong (>30%)[10,11] Descriptive statistics including the mean, standard deviation and percentage was used to analyze data.

Results

The socio-demographic features studied showed that 39(36.8%) of the women had completed primary, secondary or high schools and 59 (54.7%) had completed diploma, college or postgraduate studies, and of their husbands there were 47 (55.6%) completed diploma, college or postgraduate studies and 39 (40.2%) completed primary, secondary or high schools. Thirty eight (34.9%) were teaching staff and 53(50.9%) housewives. There are 81 (75.5%) married, 8 (7.6%) unmarried, 9 (9.4%) divorced and 8 (7.9%) widow. About 12 (14.4%) of them had high level family income, 85(77.4%) had middle level and 9 (8.5%) had low level income (Table 1). The five-year and lifetime BCR variables studied showed that the mean age of women was 43.44± 11.3 years (range 35–67 years) and that 50 (45.3%) of the participants had their menarche at the age of 12–13 years, 32 (29.2%) of women had their first live birth between the ages of 20–24 years and 22(19.8%) between 25–29 years. There were 10 (9.4%) of the participants reported having first degree relatives who had diagnosed with breast cancer. Only 5 (3.8%) women reported two first-degree relative with breast cancer, four (4.7%) had undergone one breast biopsy and 8(8.5%) had more than one. five of the participants reported having atypical hyperplasia (Table 2).Based on the modified Gail model, the women in this study had a mean five years risk of 1.25± 1.46 and a mean of lifetime risk of 13.11± 12.76%. The minimum and maximum values were 0.3%, 7.1% and 3.7%, 39.6% for the five years and lifetime risks, respectively. In comparison with women of the same age and average risk factors, 19 (7.6%) had a higher five years risk and 6 (2.4%) had higher lifetime risk (Table 3).

Table 1: Socio demographic information about the women included in the study, 35 years and over (N=106)

Occupation	Martial status	Family income	Education level	Husband educ. Level
Teaching staff (38)34.9%	Married (81)75.5%	Low (9)8.5%	Prim.School (23)20.8%	Prim. School (14)14.4%
Employees (12)11.3%	Unmarried (8)7.6%	Middle (85)77.4%	Med.school (11)11.3%	Med .school (12)12.4%
Workers (1)1%	Divorced (9)9.4%	High (12)14.1%	High school (5)4.7%	Highschool (13)13.4%
Students (2)1.9%	Widow (8)7.5%		Diploma (16)14.2%	Diploma (9)10.3%
Housewives (53)50.9%			College (20)16%	College (28)27.8%
			Higher study (23)24.5%	Higher study (10)17.5%
			Uneducated (8)8.5	Uneducated (5)4.2%

Table 2: Women risk factor values used in the BCRAT in women, 35 years and over (N=106)

Age	Age at menarche	At a first live birth	No. of first degree relatives with BC	Having a biopsy
35-44 (59) 52.8%	Unknown(24) 23.6%	Not married(8) 8.5%	One relative (10) 9.4%	One biopsy (4)4.7%
44-54 (34) 30.2%	7-11 (4)3.7%	Unknown(2) 1.9%	>One relative (5) 3.8%	>One biopsy (8) 8.5%5 had atypical hyperplasia

Age	Age at menarche	At a first live birth	No. of first degree relatives with BC	Having a biopsy
55-64 (12) 16%	12-13(50) 45.3%	No birth (6) 5.7%	Zero relative 91(85.84%)	
>65 years (1) 1%	>14(28) 27.4%	>20years(20) 19.8%		
		20-24years(32) 29.2%		
		25-29years(22) 19.8%		
		>30(16) 15.1%		

Table 3: Calculated BCR in women,35years and over (N=106)

Five years risk Number and percentage	**Lifetime risk**
Standard of Gail Model 1.02%	Standard of Gail Model 11.21%
Mean of five-year risk of all Women 1.25± 1.46%	Mean risk of all women up to age 90 years 13.11± 12.76%
Low risk 91(85.84%)	Usual risk 91(85.84%)
High risk 15 (14.15%)	Moderate risk 7(6.60%)
	High risk 8(7.54%)

Discussion

With the increase in breast cancer rates in Iraq, it is important to screen for women at high risk for early detection and prevention. Biostatistician Mitchell Gill developed a mathematical model in 1989 to assess the risk of BCR based on the results of a large screening study of 284,780 women who underwent annual mammography screening, and because of the reliability and validity of the GM., It was used in the current study[18].

As 18.1% among the USA women over the age of 40 in Mermer and Meseri study whereas it was 2.5% among the women aged 35–60 in Abu-Rustum et al. study[12,13]. Ewaid and Al-Azzawiin their study[14] found that the five year risk rate in Iraqi women was 0.95% and the lifetime risk was 11.134%. Fikreeand Hamadeh[15] reported that the five year risk in Bahraini women was 0.7% and the lifetime risk was 9.3%. Erbil et al[16]

The Gail model qualifies women age 35 and older to try BC prevention if they have a five-year risk of 1.7% or more. In this study, there were 15 women who had a 5-year higher risk. Therefore, these women are eligible for BC prevention

Strategies. Iraqi Cancer Council statistics showed an increase in the incidence of BC in young Iraqi women [ICB, 2010]. In this study, although the risk at five years and during ninety years of life was lower than the standard for the Gail model, those with a Gail score equal to or greater than 1.7% were considered high risk and recommended regular mammograms. [17,18] Chemoprophylaxis[32] and even prophylactic mastectomy [18,17].

Conclusion and Recommendation

Women's Iraqi should be given the chance to survey their risk of BC and give them direct screening strategies. The relationship between the possibility of ethnic differences and the environmental pollution might affect the applicability of the Gail model, so these factors must be studied well.

In Silico Study Chitosan Snail Shell as Antioxidant Through Interesting NRF2-KEAP1 in Hypercholesterolemia

Umarudin[1], Dewi Ratih Tirto Sari[2,3], Fatchiyah Fatchiyah[2,3], Sri Rahayu[2,3], Sri Widyarti[2,3], Warsito[4]

[1]Student, Department of Biology, Faculty of Mathematic and Natural Science, Brawijaya University, Malang, Indonesia, [2]Lecturer, Department of Biology, Faculty of Mathematic and Natural Science, Brawijaya University, Malang, Indonesia, [3]Researcher, Research center of SMONAGENES, Brawijaya University, Malang, Indonesia, [4]Lecturer, Department of Chemistry, Faculty of Mathematic and Natural Science, Brawijaya University, Malang, Indonesia

Abstract

Hypercholesterolemia is one of the leading causes of endothelial dysfunction. Hypercholesterolemia can result in oxidative stress that exceeds antioxidant defenses. One of the antioxidants is snail shell chitosan. The research aimed to analyze the study of *in silico* chitosan snail shell as an antioxidant through inhibition of nrf2-keap1 in hypercholesterolemia. This research method is the 3D structure of Keap1 and Nrf2 (ID: 5CGJ) proteins. Canonical chitosan smiles ($C_{56}H_{103}N_9O_{39}$) (ID: 71853) were modelled with Corina software to obtain 3D structures. Chitosan was analyzed by Lipinski test. Molecular docking was analyzed by interacting chitosan, Nrf2 and Keap1 with HEX 8.0 software and visualized by discovery studio version 4.1. Data analysis was used descriptively. The results of the study of chitosan with Keap1 and Nrf2 had 43 amino acid residues (GLU444, ARG447, ASN387, ASP448, GLU79, LEU84, ALA407, TRP450, LEU76, ALA407, GLU447, LEU452, ASN495, ASN387, GLN73, GLU72, ASP79. ASP538, ASP589, GLU82, PHE70, LEU75, ASP77, GLY80, GLY81, LEU84, GLU540, ASP589, PRO549, ASN469, ASN517, ARG536, VAL536, THR545, ASP589, LEU84, GLU540, ASP538, ASP58979) and hydrogen, electrostatic, and hydrophobic bonds. Snail shell chitosan has potential activity as hypercholesterolemia because it has an affinity with nrf2 and keap1 proteins which can prevent the switch on gene process in the formation of antioxidants.

Keywords: *Hypercholesterolemia, oxidative stress, snail shell chitosan, NRF1, KEAP1.*

Introduction

The cholesterol diet can change the picture of lipoproteins to be more atherogenic, namely increasing LDL, lowering HDL levels, and increasing plasma cholesterol. Increasing LDL levels in the body will increase the risk of LDL oxidation caused by various factors such as free radicals. Oxidized LDL will be recognized by the scavenger receptor in macrophages and will become foam cells. The more LDL levels in the plasma, the more it will be oxidized and captured by macrophage cells, causing accumulation of macrophage cells. This accumulation causes reverse cholesterol transport to become unbalanced, which results in hypercholesterolemia[1,2].

Oxidative stress occurs due to an imbalance between increased free radical production and decreased antioxidant capacity. The decline in antioxidants is mainly due to impaired activation of nuclear factor-erythroid-2 related factor 2 (Nrf2) and keap1, the transcription factor that regulates genes encoding antioxidants and detoxification enzymes[3-5].

In the presence of oxidative stress, electrophiles and reactive oxygen species (ROS) can react with KEAP1

sensor cysteines, including cysteine 151 (C151), C273, and C288, possibly releasing NRF2 from KEAP1-mediated degradation[6-8], so that newly synthesized NRF2 occurs in the nucleus and activates the expression of scattered Nrf2 and degradation occurs in the cytoplasm[9]. KEAP1-NRF2 activates NRF2. Activated NF2 accumulates in the nucleus, resulting in interactions with transcription factors and other cofactors to regulate the transcription of the target gene, which encodes a protein whose role is antioxidants[10].

Exogenous antioxidants are needed to compensate for this is snail shell chitosan. So far, snail shell chitosan has not been studied scientifically as an antioxidant *in silico*. In this study, using in silico with computational modelling which is closely related to in vitro and in vivo experiments. This modelling plays a role in the field of medicinal chemistry to find bioactive compounds that have drug candidates[10-13] in silico test using docking molecules that are predicted as target cells to be determined. This research aims to analyze preliminary studies of molluscs as chitosan producers and to predict activity as antioxidants.

Method

The 3D structures of Keap1 and Nrf2 proteins (ID: 5CGJ) were downloaded from the PDB database. Canonical smiles chitosan ($C_{56}H_{103}N_9O_{39}$) (ID: 71853) from the PubChem database modelled with Corina software to obtain 3D structures. Chitosan was analyzed by Lipinski test. Molecular docking was analyzed by interacting chitosan, Nrf2 and Keap1 with HEX 8.0 software and visualized by discovery studio version 4.1. The analysis includes H-bond, SAS, Hydrophobicity, Aromatic, Interpolated Charge, and Ionizability.

Results

Table 1 shows that the conditions that must be met by a compound based on Lipinski are a molecular weight of the compound <500 Da, there are no compounds with more than 5 hydrogen bond donors, the number of hydrogen acceptors <10, while for molar refractivity ranges from 40-130 and the value Log P <5, the ligand tested has met the requirements so that it is confirmed to be able to pass through the cell membrane.

Table 1. Lipinski Test Results

Ligand	Molecular Weight (Da)	Number of Hydrogen Bonds	Amount of Acceptor Hydrogen Bonds	Molar Refractivity	Log p	Term
Chitosan	312 Da	5	6	77.146	-0.053	Meets specifications

Discussion

In this study, the molecules studied had a higher number of rotatable bonds and had a good ability to bind Nrf2 and Keap1 because the molecules used were polymers. It is seen that the number of hydrogen bond acceptors is directly related to the binding properties of the amino acid residues; It can be seen that the results of docking chitosan→keap1, chitosan + Keap1→Nrf2, chitosan→Nrf2, chitosan + Nrf2→Keap1. The results of chitosan docking to 1 amino acid residue were SER391, SER408, THR388, ARG447, GLU444, ASP389, GLU444, ARG447, ASN387, and ASP448 with the hydrogen bond category. Docking, chitosan + Keap1→Nrf2 amino acid residues produced are SER391, SER408, THR388, ARG447, GLU444, ASP389, GLU79, LEU84, ALA407, TRP450, LEU76, ALA407, GLU447, LEU452, ASN495, GLN387, AL73A69, ASP77, THR80, LEU84, PHE83, GLU79 with the hydrogen bond category, the resulting docking results of chitosan→Nrf2 amino acid residues are LEU84, ALA72, GLN75, GLU72, ASP77, GLU79, ASP79, ASP77, LEU84, and GLU79 The bonds obtained are electrostatic and hydrogen. In contrast, the results of chitosan + Nrf2→Keap1 docking are ARG536, ASP538, LEU84, ALA72, GLN75, ASP589, GLU82, PHE70, LEU75, ASP77, GLU79, THR80, GLY80, GLY81, LEU84, GLU540, ASP589, PRO549, ALA69, PHE83 ASN517, ARG536, VAL536, THR545, ASP589, LEU84, ASP77, GLU540, ASP538, ASP589, ALA548, TRP591 and GLU79, electrostatic, hydrogen, and hydrophobic bonds.

The docking results showed that the different amino acid residues were chitosan →keap1: GLU444, ARG447, ASN387, and ASP448. Chitosan + Keap1→Nrf2 are GLU79, LEU84, ALA407, TRP450, LEU76, ALA407, GLU447, LEU452, ASN495, ASN387,

GLN73. Chitosan→Nrf2: GLU72, ASP79. Chitosan + Nrf2→Keap1: ARG536, ASP538, ASP589, GLU82, PHE70, LEU75, ASP77, GLY80, GLY81, LEU84, GLU540, ASP589, PRO549, ASN469, ASN517, ARG536, VAL536, THR545, ASP538, LEU ASP589, ALA548, TRP591 and GLU79.

Hydrophobic interactions play a role in determining the stability of the ligands against androgen receptors. Hydrophobic interactions avoid a liquid environment and tend to cluster within the globular structure of proteins. The results of this study are by several previous studies which stated that drug candidates generally have the number of hydrogen bonding bonds[14-16], because the average number of hydrophobic atoms in drugs is generally[16], with one to two donors and three to four acceptors[17], so that hydrophobic interactions play an important role in drug candidates because they can increase the binding affinity between target interfaces. The in silico test proved that the binding affinity and drug efficacy associated with hydrophobic bonds could be optimized by combining them at the hydrogen bond site[18,19]. However, this approach is not the only primary method for designing a drug. The formation of hydrophobic bonds minimizes the interaction of nonpolar residues with water. Chitosan + Keap→Nrf2 obtained 3 hydrophobic bonds, namely ALA407, TRP450, and LEU76. Chitosan + Nrf2→Keap1 obtained 3 hydrophobic bonds, namely ALA69, PHE70, and PHE83. The residue on these amino acids is hydrophobic and nonpolar. Nonpolar (hydrophobic) amino acid residues tend to form groups in the interior of the protein[20,21].

Based on the value of the bond energy obtained, it shows that chitosan compounds have potential activity as hypercholesterolemia because they have an affinity and form hydrogen-protein bonds between chitosan and nrf2 and keap1 proteins, so that chitosan can block receptors (keap1) and ligands (nrf2) so that they can be inhibited.

Conclusion

In conclusion, Snail shell chitosan has potential activity as hypercholesterolemia because it has affinity by forming hydrogen bonds with nrf2 and keap1 proteins and can inhibit hypercholesterolemia in silico.

Conflict of Interest: The author declare that they have no conflict of interest.

Abstract

In this paper we used a biological method to prepare gold nano particles as a simple technique, environmentally friendly and limited toxics compared with chemical and physical method. Where used *Pseudomonas* bacteria supernatant to prepare gold nano particles and use this supernatant to reduction gold salt ($HAuCl_4.4H_2O$) and converted to AuNPs. XRD measurement showed the average the crystallite size ranging from (9.2-11.4) nm, UV-VS spectrum exhibited the maximum absorbance peak at (530)nm and optical energy gap (E_g = 1.88)e.v, FESEM image showed the shapes of AuNPs as (spherical and semispherical), TEM image showed the formation of particles as clusters, spherical and hexagonal shapes. AuNPs was used as anticancer cell line where testing against breast cancer line (MCF-7) and interested result indicated that can be used AuNPs in reliably as an active treatment to those have breast cancer (MCF-7).

Keywords: *Gold Nanoparticles, MCF-7, Anticancer.*

Introduction

Gold is one of precious metals that was discovered in nature by human and used in jewelry making Gold is also used not only for jewelry, but also for industrial uses and applications in the fields of biology and medicine etc.[1][2][3][4][5]

Physical and chemical method succeeded in the manufacture of many nanomaterials that are high purity, but in return there are negative sides such as the high cost and risks of chemical reactions The biological method has no chemical risks as well as is less costly and environmentally friendly. Biosynthesis of gold is being different size from Several nanometer to hundreds of nanometers and different shapes.[6][7][8]

AuNPs are formed by the reduction of Gold salts in the solution through various reduction agents in the solution.[9][10]

Rapid reduction results NPs in large particles and spherical shape in general as for slow reduction results NPs in small particles.[7][9]

Safety aspect of NPs: The properties of Many Materials change when they are reduced to nanoscale as the surface area of the particles increased resulting in interactions with environment. Nanomaterials are of limited toxicity and therefore have the advantage in medicine, biochemistry and nanotechnology.[11][12][13][14]

Materials and Method

To preparing the Nutrient broth medium (NBM) we suspended 0.8 gm of the medium in 100 ml deionized water. Mix well and dissolve with frequent agitation for one minute until complete dissolution. And finally sterilizes it in Autoclave for 15 min in 15 lb and 121 C.[15]

***Pseudomonas* culture:** To preparing of *Pseudomonas* culture solution, under sterile environment, we were

taken a full loop of new activated *Pseudomonas* bacteria (which provided from biological department- Science Faculty/University of mustansiriyah) and cultured in 100 ml flask of nutrient broth medium then incubated for 24hr under 37 ºC.

Preparation of bacterial supernatant: After 24hr of culturing, we centrifuge the culture tube at 5000 rpm, and take the supernatant in quiet and kept it in +4 ºC, until preparing gold nanoparticles.

Preparation 0.02 M of gold (III) chloride tetrahydrate ($HAuCl_4.4H_2O$) stock solution:

To preparation of a stock solution of gold salts, dissolved 1gm of ($HAuCl_4.4H_2O$) in 100ml of deionized water. Then we calculated the stock concentration according to the following equation:-[16]

$$M = \frac{Wt}{Mwt} \times \frac{1000}{V}$$

M=Molarity,

Wt=weight of ($HAuCl_4.4H_2O$) (1)gm

Mwt= Molar mass of $HAuCl_4.4H_2O$ is 411.8476 g/mol

V=Volume of deionized water=100ml

$$\text{So: } M = \frac{1gm}{411.8476\ gm/mol} \times \frac{1000}{100ml}$$

= 0.02 Molar

Synthesis of (Au-NPs) by using *Pseudomonas* bacteria: To synthesis of Au-NPs, 0.5 ml of $HAuCl_4.4H_2O$ stock solution which prepared was added dropwise in 25 ml glass tube with screw cupcontains of 2ml of bacterial supernatant and 7.5 ml deionized water as shown (figure 1) a,b,c, the final volume will be 10ml. The concentration of $HAuCl_4.4H_2O$ in this solution calculated according to the following equation:-[17]

$$C1 \times V1 = C2 \times V2$$

$$0.02 \times 0.5 = C2 \times 10$$

$$C2 = \frac{0.02 \times 0.5}{10} = 0.001\ Molar$$

Then, the glass tube was placed in the heating mantle with inserting the thermometer and thermostat, the temperature was raised until 80-85ºC for 30 min, the color of the solution will change to dark red which indicated to synthesized the gold nanoparticles. Also, we controlled the pH value (7.5-8) of this reaction by added 0.25 ml of NaOH at concentration 0.1 Molar.

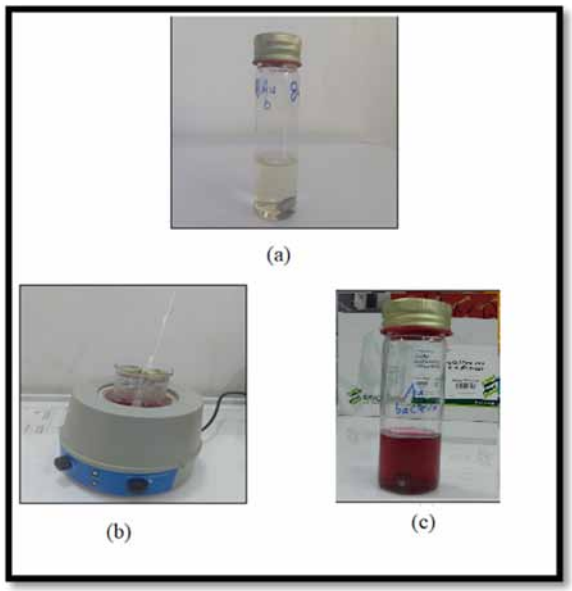

Figure (1) prepared gold nanoparticles from bacteria supernatant

(a) Solution contain of (0.5 ml of HAuCl4.4H2O+ 2 ml of bacteria supernatant+ 7.5 mlD.W)

(b) Solution of Au NPs during preparation

(c) Solution of Au NPs after preparation

Results and Discussion

XRD analysis: Formation of gold nanoparticles by biological method using Bacterial supernatant was assured by XRD spectrum as shown in figure (5) peaks (111) (200), (220), and (311) point out FCC phase of gold nanoparticle, the peak broadening in XRD pattern indicates that small nanocrystallite are work out in specimens.

The average crystallite size was calculated using scherrer's equations and its values was found to be in the range (9.2 to 11.4) nm. Result of figures (2)a are agreement with[18]

UV-Vis measurements: The absorbance spectra for sample of gold NPs solution prepared from bacteria supernatant was investigated by uv-vis spectroscopy. (Figure 2) b shows absorbance spectra of Au NPs solution at concentration (100 ppm) with images of collides. Investigation shows presence of absorbance peak at 530

nm for NPs prepared from bacteria supernatant. Which corresponding to surface plasmon resonance (SPR) of Au NPs, and this result is agreement with[19][20][21][22]

The optical energy gap (E_g^{op}) of AuNPs is calculated from the following equation:

$$\propto h\upsilon = B(h\upsilon - Eg)^n$$

Where ($h\upsilon$) is incident photon energy

(B) is constant, (n) is constant take Value (1/2, 3/2, and 3) depend on type of the optical transitions (direct or indirect)

where the values of energy gap for AuNPs solution prepared from bacterial supernatant (E_g^{op} = 1.88) e.v, the reason for appearance band gap energy due to quantum size effect.

The figures (2)a,b,c show XRD pattern, Absorbance and optical energy gap for gold nanparticle

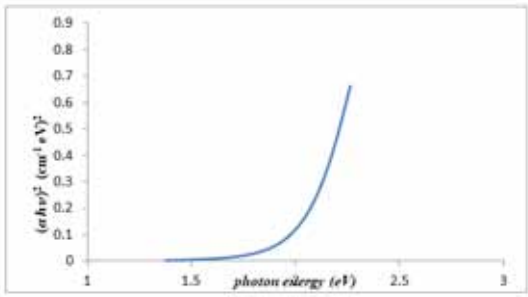
(b)



(c)

Figure(2): a) XRD pattern of gold nanoparticles prepared by Biological method using Bacteria supernatant, b) Absorbance as a function of wavelength for gold colloids nanoparticles prepared by Biological method using Bacteria supernatant, c) Variation of ($\alpha h\nu$)2 with hv for direct transition in Au NPs prepared from Bacteria supernatant

FE-SEM: By examining the FE-SEM of gold nanoparticles prepared from Bacteria supernatant, as shown a (figure 3 a) imagewith magnification (100 kx). the shapes were semispherical and spherical with random shapes. and it can be note that the agglomeration percentage is high in the image. The average of grain size was found in the range from (12.13 – 37.8)nm.

TEM: Figure (10b,c) show the TEM image of Gold nanoparticles - prepared from bacterial supernatantat (pH = 7.5-8) and concentration (100ppm), with (125000x) magnification, the image reveal formation of gold nanoparticles with spherical,semispherical and hexagonal shapes. The average particle diameter between (10 to 40) nm, which agreement with FE-SEM result and very closely with XRD result.(figure b,c)

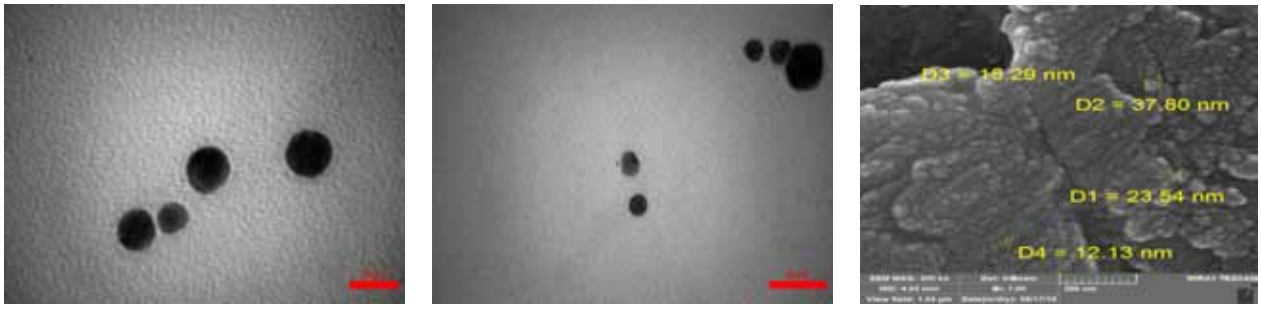


Figure (3)a: FE-SEM images recorded by deposited gold-DW nanoparticles on pure glass slide; b,c: TEM image of gold nanoparticles prepared by Biological method using Bacteria supernatant

Cytotoxic Effect of synthetic Au-NPs using *Pseudomonas sp.supernatant* on MCF-7 Tumor Cell Lines using MTT colorimetric assay: The cytotoxic activity of Au-NPs which synthesized via using *Pseudomonas sp.* supernatant was determined by MTT colorimetric assay. As shown in Table 1 and (figure 4), the cytotoxic (Viability percentage) of created Au-NPs was not affected significantly (p>0-05) with 6.25 and 12.5 µg/mL concentrations. While, the cytotoxicity was increasing significantly with increasing of synthesized Au-NPs concentrations (P<0.05). Moreover, this assay showed that the minimum inhibitory concentration of MCF-7cells and WRL68 by reaction with synthesized Au-NPs were obtained at 6.25 µg/mL (95.602±1.505 and 95.833±0.579 respectively). However, the maximum inhibition concentration at 400 µg/mL (54.707±1.124 and 77.585±1.238 respectively; Table (1). Also, when reacted of synthesized Au-NPs with the normal cell line cells, the median lethal dose (IC50) was 117.4, while it was reduced to 51.66 in MCF-7 cells (figure 11)and this result agree with[23].

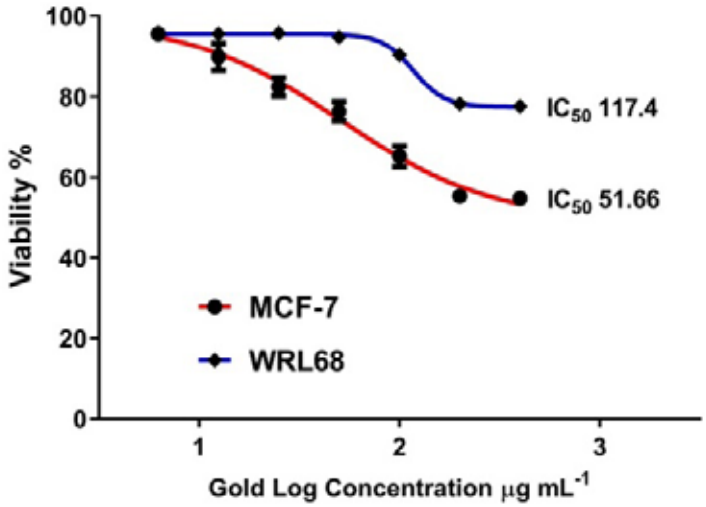

Figure. 4 Comparison of the viability percentage of MCF-7 cells and WRL68 versus the logarithm of the concentration of synthetic Au-NPs using *Pseudomonas* sp. supernatant.

Table 1: Viability percentage of MCF-7 and WRL68 tumor cell line, and degree of freedom (Df) regarding to different concentrations of synthesized Au-NPs using *Pseudomonas sp.*supernatant

Molecular Detection of Tumor Necrosis Factor-Alpha (TNF- a) Gene in Mycotic aborted Placenta of Ewes Using RT-PCR

Bushra Hamza Fares[1], Hameed Abdul Hussain Al-tememy[2], Ban Abbas Abdulmajeed[3], Mohammed M. Dakheel[4]

[1]Assistant Professor, Department of Pathology/Faculty of Veterinary Medicine/University of Kufa/Iraq, [2]Scientific Researcher, Department of Poultry Diseases/Najaf Veterinary Hospital/Iraq, [3]Professor, Department of Pathology/ College of Veterinary Medicine/University of Baghdad/Iraq, [4]Lecture, Department of Veterinary Public Health/ College of Veterinary Medicine/University of Baghdad/Iraq

Abstract

Background: Abortion is associated with altered inflammatory molecule expression at the maternal-fetal interface. (TNF-alpha) are inflammatory proteins and display cytokine as a function that enhances the leukocyte recruitment to the inflammatory site.

Objectives: This work aimed at establishing the TNF-alpha gene expression in mycotic aborted placental animals as opposed to normal delivery.

Materials and Method: Using the technique Real Time-Polymerase Chain Reaction (RT-PCR), TNF-α DNA, tested in the mycotic aborted Placenta group (15 cases), normal delivery group (15 cases).

Results: The levels of TNF-α DNA expressed in the Placenta varied significantly between the two groups ($P<0.05$), respectively. The expression of TNF during abortion was significantly higher than in normally delivered models.

Conclusion: These findings indicate that both cytokines Th1 and Th2 play a key role in the pathogenesis of abortion. TNF alpha is likely a source of abortion's genetic susceptibility. There had been a strong correlation between the two cytokines and abortion.

Keywords: *Tumor necrosis,Factor-alpha, (TNF- a) gene, RT-PCR, Mycotic abortion.*

Introduction

Inflammatory processes caused by host resistance to infection or by infection-independent immune disorders pose a major challenge for successful pregnancy[1,2]. Inflammatory mediators, particularly tumor necrosis factor-a (TNFA), which act on the gestational tissues to damage the supply and function of the placental blood[3] and cause fetal injury[4], eventually leading to placental and fetal death. In fact, the predominance of cellular immunity in abortion results in a rejection of the embryo.TH-1 type cells induced by the infection may cross the interface of the fetus or may produce trophoblasticinflammatory cytokines[5].

The development of these cytokines is partially regulated by genetic regulation and the level of production of cytokines has been found to be associated with genetic polymorphisms, particularly TNF alpha and IFN gamma[6]. There is a relation between TNF-a gene polymorphism and abortion risk[7]. Mycotic abortion (fungal abortion, mycotic placentitis), caused by many fungi, is a cosmopolitan, contagious, intermittent, animal, particularly sheep, infection of the genital tract;moreover, Magee and Cox[8] found that passive

serum transfer from the Formalin-killed spherules (FKS) mice vaccine did not protect the recipients; however, Raghupathy[9] who also noticed that neither serum nor immune B-cells transferred protection against mice attack. However, the role of a coccidioidomycosis humoral-immune response remains unclear[10].

In this study, real-time polymerase chain reaction (RT-PCR) detected the expression of TNF-α DNA in mycotic aborted sheep for Placenta; thus, revealing the link between aberrant TNF-α DNA expression and abortion. It is the first study that showed that mycotic aborted animals had increased expression of alpha TNF. In fact, changed expression of those inflammatory molecules can contribute to the pathophysiology of abortion.

Materials and Method

Fifteen samples of the mycotic of the aborted placenta, which was collected from aborted ewes, were collected from various areas of Al-Najaf City, and fresh placental tissue was subjected to complete DNA extracted using Genomic DNA Mini Extraction Kit (KAPA BIOSYSTEM, USA).

These samples were taken from November 2018 to November 2019, following instructions from the manufacturer RT-PCR for the molecular analysis of the genes TNF-alpha. Fresh placental tissue was subjected to complete DNA extraction using the Genomic DNA Mini Extraction Kit (KAPA BIOSYSTEM, USA), following the manufacturer instructions.

Quantitative Real-time PCR: Real-time PCR was made using TNF alpha primers (forward GAA TAC CTG GAC TAT GCC GA, reverse CC TCA CTT CCC TAC ATC CCT) according to the manufacturer's protocol (Applied Biosystem).

Quantitative RT-PCR reactions were conducted in 20 µl containing 10 µl KAPA SYBER* (KR0393_S – v2.17) FAST qPCR Master Mix(2X), 0.4 µl forward Primer(10 µM), 0.4 µl Reverse Primer(10 µM), 0.4 d UTP (10 µM), 0.4 ROX High/Low, 0.4 µl KAPA RT Mix (50x), and 3 µl deionized water DNA template up to 20 µl. The cycling conditions were as follows for all genes: 10 min at 95 ºC, 40 cycles of 30 seconds at 95 ºC,40 cycles of 30 seconds at 95 ºC,1 min at 55 ºC and 1 min at 72 ºC followed by a melt curve starting at 65 ºC rising to 94 ºCat 0.3 per-second**.**

Statistical Analysis: The differences between the means were analyzed with Student's t-test for unpaired samples; the *P-value <0.05* was considered to be significant the differences between. Analysis of the aborted and normal expressions of TNF alpha placental samples were performed using SPSS v.19.0 (SPSS Inc., Chicago, USA).

Results

The placenta immune response was characterized by an analysis of the aborted TNF-α andnormal placecentomes of delivery, Table(1). All the cytokines showed substantial increases compared to the animals given one. Those results were analyzed when aborted animals did not show any differences with the control sheep;thus, the interpretation was identical regardless of the duration of the abortion. Similarly, the increase in TNF-α transcription among the aborted groups was similar.

Table 1: Comparison of cytokine expression between two groups

	Mean	N	Std. Deviation	Std. Error
Normal	17.5200	15	0.76278	0.31141
Aborted	22.1067	15	3.05502	1.24721

TNF-α DNA levels expressed in Placenta differed considerably between the two groups (P<0.05) respectively. The number of cases showing over-expression of TNF alpha in the aborted placenta was 15 of 20 (80 %), which was statistically important from controls.

In placental aborted research median alpha, TNF fold transformation was found to be 22.1067 Relative to the controls which were 17.5200.

Discussion

The inflammatory response in abortion which is necessary for anordinary pregnancy is sought to be altered. Nonetheless, a motherly immune response is a primary determinant of success or failure in pregnancy[11]. However, the inflammation of mediated pregnancy is a well-studied phenomenon in rodents, which is used as a basis for spontaneous pregnancy loss. Further, Aberrant inflammatory and environment are related to uteroplacental perfusion dysfunction, the incidence of thrombotic events, and placental and fetal hypoxia[12].

Several studies on the role of TNF polymorphisms show the impact of the various alleles on *in vitro* and *in vivo* production of TNF levels[12]. Nevertheless, a recent study showed that not only polymorphisms within the TNF cluster are necessary to regulate the production of TNF but also receptors (TNF R)[13]. This result suggested that research into polymorphisms within the TNF cluster and TNF receptors will be important in understanding the role of TNF regulation in a given disease.

A substitution of (G) to (A) in role-308 in the tumour necrosis factor-alpha (TNF-alpha) gene promoter increases the transcription of TNF-alpha *in vitro* by around 6 to 9 folds[13]. Paracoccidioidomycosis (PCM) has associated polymorphisms in other genes, such as cytokines, which play a role in the immune response,which involve polymorphisms of IL-10(1082 G/A) and TNF-α (-308 G/A) in PCM patients It has been found that while homozygous, the IL-10-1082 G allele may be correlated with an increased risk of disease contracture[14].

Placental cytokines such as IL6, TNF α, and TGF β have been reported to play roles in necrotic and aponecrotictrophoblast cell death by influencing caspase and endothelial cell activation activities.IL6, IL1, and TNF α are thought to play important roles in early pregnancy and also to be elevated in inflammatory states[15]. High levels of pro-inflammatory molecules such as TNF a, IFN-gamma, IL-6andIL-10 and inflammatory leukocytes (macrophages, neutrophils, lymphocytes) were found in women with recurrent pregnancy loss (RPL) compared to women with normal pregnancy[16].

Baud and Karin[17], elevated levels of pro-inflammatory cytokine in the macrophage triggered by IFN-gamma and TNF-alpha.IFN γ was formed from trophoblasts and endometrial mucosal cells at moderate levels. It's consistent with other findings from the mouse study[18]. Since its ability to control immunologically important transcription, this is a type II interferon and controller of a wide variety of cellular processes. Therefore, this study hypothesized that maternal overexpression of the TNF alpha gene may increase the recruitment of inflammatory leucocytes in the maternal-fetal interface,resulting in uteroplacental perfusion deficiency, development of thrombotic events and placental hypoxia, finally abortion of embryos. This study also examined the altered expression of TNF alpha in 15 aborted placenta versus 15 normal placenta, subjects as controls. TNF alpha gene has been evaluated using quantitative real-PCR to assess if the pattern of differential expression of such transcript analysis has been performed.

The level of TNF alpha protein in the placental tissue of the aborted ewes has increased significantly ($p < 0.05$) compared to controls. Thus, this is the first study that predicted the role of the inflammatory molecules TNF alpha. The research opens up a new perspective to understanding the role of TNF alpha in pregnancy maintenance and outcome. In this context, Th2 or Th3 cytokines, such asIL-4, IL-10or TGF-b, would promote pregnancy survival, while the development of excessive pro-inflammatory cytokines (i.e., TNF-a Or IFN g) would assess fetal rejection[19].

The TNF-alpha is primarily expressed by mononucleomacrophage, CD4 + Th1, cell NK, etc. Yet apart from these immune cells, certain reproductive tissues can also express this cytokine[13]. It was observed that the expression of TNF-α DNA decreased significantly in normal delivery compared to that of abortion, which was consistent with Kirwan *et al.*[14] findings. Monzón-Bordonaba *et al.*[22]. reported that lower TNF-α concentrations could improve pregnant women's energy metabolism and their embryo development,increase synthetic progestagen and choriogonadotropin levels, and stimulate trophoblast to generate urokinase-type plasminogen activator (uPA),It promotes the deterioration of decidual cell ectomatrix and placenta implantation and eventually plays a role in pregnancy sustainability.

Chaouat *et al.*[23]. found that higher TNF-α concentrations can lead to abortion by the promotion of trophic cell apoptosis, the elevation of synthetic PG E2, excitation of uterine smooth muscle,stimulation of Th1 type of immunological reaction, rejection of embryonic tissue, coagulative system activation leading to placenta trophic vessel thrombosis. Thus, the proportion of CD4 + T cells in the peripheral blood of early pregnant women had decreased significantly, presumably as a result of physiological changes in several hormones during pregnancy contributing to certain changes in the maternal immune system and ensuring the development of relatively lower levels of TNF-α in pregnant maternity.

A study showed that abortion was related to an irregular rise in the TNF-α serum protein, which the expression of TNF-α increased significantly locally in

different types of cells at the maternal-fetal interface during a spontaneous abortion, and 94% of these TNF-α were located in the mother's peripheral blood cycles[24]. Furthermore, Zenclussen *et al.*[25] found that P-selectin within the vascular wall of decidua is significantly increased in patients with normal spontaneous abortion,and, in combination with P-selectin ligand on the surface of TNF-α-expressing Th1 cells, local migration of Th1 cells from the peripheral blood to the maternal/fetal interface results.

Chaouat *et al.*[26]reported that PBMCs were accumulated locally through a series of complicated mechanisms at the maternal-fetal interface and secreted a larger amount of TNF-α in the form of paracrine or autocrine, possibly resulting in abortion.Although the causal-effect relationship between abnormal expression of TNF-α and abortion is not yet clear, abortion may be correlated with TNF-α gene polymorphisms[27].A study has recently found, from the immunogenetic point of view, that the gene polymorphism occurred in women with a tendency to abortion, cytokine modification may typically be affected by many factors during a spontaneous abortion[28]. Nevertheless, the above study raised a train of new thoughts, the exact mechanisms of TNF-α leading to abortion are not completely understood,and whether the initiator or the successor case is an irregular expression has not been confirmed, requiring more research on many aspects of gene polymorphism, gene transcription, and expression of TNF-α and INF gamma receptors. Moreover, a recent study reported that a significant link between recurrent pregnancy loss and polymorphisms were studied. This research confirmed that TNF-α polymorphisms might suscept factor of recurrent pregnancy loss cases. Therefore, this study concluded that TNF-α polymorphisms were the possible genetic problem of pregnancy loss[29].

Detection of *Legionella pneumophila* and *Legionella dumoffii* Biochemically in Water Samples in Baghdad City, Iraq

Jundi Alak Mahdi Al-Buhilal[1], Taghreed Khudhur Mohammed[1]

[1]*Assistant Professor/Institute of Medical Technology-Almansour, Middle Technical University, Baghdad/Iraq*

Abstract

Background: Legionellae can be isolated from various sources of water. *Legionella pneumophila* is transmitted via contaminated water and caused many diseases like pneumonia; lungs abscesses and fever.

Objectives: Isolation and identification of *L. pneumophila* from environmental samples; study the factors that affect the frequency of *L. pneumophila*; and some oxidizing substances on their growth.

Materials and Method: A total of one hundred water samples were collected from Cooling tower; Water tanks; Tap water and Swab from inner tap water. All samples were cultured on Buffered charcoal yeast extract (BCYE) agar and Buffered charcoal yeast extract (BCYE) broth to isolate *Legionella pneumophila* and *Legionella dumoffii*. Effect of pH; temperature; chlorine; Iron and effect of soluble zinc on *L. pneumophila* growth were studied.

Results: The isolates gave positive results for the tests of catalase, oxidase, gelatin degradation, nitrate reduction and beta-lactamase. Iron; Soluble Zinc; Chloride; Calcium hardness ($CaCO_3$); Turbidity and silver were ≤ 3ppmas; 1-3 ppmas; 0.2-0.5 ppm; 600 ppm; ≤ 0.3 and 3 ppmas respectively. The distribution of *L. pneumophila* in the water samples were studied.

Conclusion: Fatal*L. pneumophila* may be transmitted by drinking contaminated water and led to death because they caused pneumonia.

Keywords: *Legionella pneumophila, Legionelladumoffii, Water sources, Antibiotic resistance.*

Introduction

Legionella pneumophila (*L. pneumophila*) is a Gram negative bacillus, grow and multiply under aerobic conditions in the presence of cysteine and iron, hydrolyses gelatin and produces urease. It is positive for oxidase and catalase. The colonies colour is white to greyish. It grows on yeast extract agar[1]. It has been isolated from patients suffering from Legionnaisis (respiratory system infections), drinking water, lakes, hot water tanks and cooling towers. *L. pneumophila* isolated from tap water; and from tankers in Baghdad and Basra cities. Many Iraqi researchers found that 75 isolates of *L. pneumophila* were isolated from 96 water samples which susceptible to many antibiotics (Gentamicin, Streptomycin, Rifampin, chloramphenicol) and resistance to Penicillin and Cephalothin [2]. Another study revealed that one hundred ten*L. pneumophila* isolates were isolated from cooling towers in General Company for the manufacture of biofertilizer/Basra, (96.3%) of isolates were sensitive to Chloramphenicol and the Refampein while (14.5%) of isolates were sensitive to Polymaxin B [3]. Forty-nine isolates of *L. pneumophila* were isolated from 222 precipitation water tanks and filtration tanks in Basra governorate. All isolates were resistant to ampicillin while susceptible to doxycycline [4]. Most of Legionnaires' Diseases (90%) caused by *L. pneumophila*, followed by *L. dumoffii*[5]. The aims of the current study are isolation and identification of *L. pneumophila* from environmental samples; study the factors that affect the frequency of *L. pneumophila*; and some oxidizing substances on their growth.

Materials and Method

1. **Water sample collection:** A total of one hundred water samples (1000 mL from each sample) were collected from:

- Cooling tower (25 samples).
- Water tanks (25 samples).
- Tap water (25 samples).
- A swab from inner tap water (25 samples).

Each sample was collected in a sterile glass container. All samples were transported to the laboratory immediately in the icebox.

2. **Water samples concentration[6,7,8]:** the concentrations of the water samples were done by centrifugation at 3000 round per minute for 5 minutes. The supernatants were discarded, and the sediments were kept in the sterile container for minutes. Then the sediments were concentrated by using Millipore membrane filter (with pore size 0.2 μm). The filter membrane resuspended with 10 mL of original water and vortexed for mixing (400 r.p.m. for 10 minutes). Then 0.1 mL of samples were cultured on *Legionella* isolation media (triplicate plates):

- Buffered charcoal yeast extract (BCYE) agar (Oxoid) containing (Yeast Extract 10 g/L; Charcoal 2.0g/L; Ferric Pyrophosphate 0.25 g/L; ACES Buffer 10.0g/L; Potassium Carbonate 2.3 g/L and Agar 14.0g/L) supplemented with a-ketoglutarate, vancomycin, polymyxin B, and anisomycin. The pH of medium adjusted to 6.9.
- Buffered charcoal yeast extract (BCYE) broth (Oxoid) to encourage the growth of *Legionella*. Then spread on BCYE agar.

All plates were incubated at 37C° with 2% CO_2. The culture media plates were examined after 2, 3, 5, 6, and 7 days of incubation to detect the *Legionella* colonies (white, convex, circular, 2 mm in diameter, like ground glass in their appearance. While the swabs of water samples were cultured onBCYE agar directly; the plates were incubated at 37C° with 2% CO_2 and then examined after 5 days of incubation.

3. ***L. pneumophila* identification:** Many biochemical tests were done to identify ***L. pneumophila*** [9]:

- Gram staining.
- Urease test.
- Nitrate test.
- Oxidase testing (using 1% *N,N,N′,N′*-Tetramethyl-*p*-phenylenediamine dihydrochloride.
- Catalase test (using Hydrogen peroxide; 3% H_2O_2).
- Gelatin liquefaction test (using gelatin agar stab).

4. **Effect of pHon *L. pneumophila* growth:** Tubes containing 10 mL of nutrient broth (Oxoid) with L-cysteine in various ranges of pH (6, 6.5, 7, 7.5, and 8) were inoculated with *L. pneumophila* isolates. All tubes after inoculation with bacteria under study were incubated at 37C° for 5 days. Then, the turbidity of each tube was measured by using turbidimeter apparatus to determine the growth of *L. pneumophila* in different pH values. After that, 0.1 mL of bacterial growth was taken from each tube and inoculated on BCYE agar; the plates were incubated at 30°C for 5 days to calculate the number of viable bacteria in different pH levels [10].

5. **Effect of chlorine on *L. pneumophila* growth:** It was donewith serial dilutions of free chlorine (0.1-1.5) mg/L in sterile 0.85% normal saline. All tubes after inoculation with bacteria; were incubated at 25°C for 30 minute. 0.01 ml from each dilution was inoculated on BCYE agar and incubated to study the effect chlorine on bacteria [11]

6. **Effect of temperatures on *L. pneumophila* growth:** All isolates were cultured on BCYE agar in incubated in different temperatures (20, 25, 30, 35, 37, 40 and 45) °C [11].

7. **Effect of soluble zinc on *L. pneumophila* growth**[12]

8. **Effect of Iron on *L. pneumophila* growth**[12]

9. **Turbidity measuring**[13]

Results and Discussion

The results showed that the isolated bacteria were Gram negative bacilli, motile, grown on (CYEA), which contains the yeast extract and cysteine. The isolates gave positive results for the tests of catalase, oxidase, gelatin degradation, nitrate reduction and beta-lactamase. They gave negative results to ferment sugars (glucose, maltose, lactose); and showed a bright blue color under ultraviolet light. So, the isolates were identified as the *Legionella pneumophila*. Analysis results of water samples were fixed in the table (1) and (2).

Table 1: Biochemical analysis results of water samples

Iron (Fe^{+2}) (ppmas)	Soluble Zinc (Zn^{+2}) (ppmas)	Chloride (ppm)	Calcium hardness ($CaCO_3$) (ppm)	Turbidity	Ag (ppmas)
≤ 3	1-3	0.2-0.5	600	≤ 0.3	3
ppmas: part per mas Ag: Silver ppm: part per million					

The distribution of*L. pneumophila* in the water samples were 22(34.37%); 18(28.12%); 15(23.43%) and 9(14.06%) in cooling tower; tanks; tab water and swab from tab water respectively. The frequency of isolates number 1 from positive samples were 22,15,14,9for cooling tower, water tanks, tab water and swabs from tab water respectively.

Table 2: Distribution of *Legionella pneumophila* isolates according to water sources

(%) Isolate of no. 2 from total positive sample	Frequency of isolate no. 2 from positive sample (%)	Isolate of no.1 from a total positive sample (%)	Frequency of isolate no.1 from positive sample	Negative sample (%)	Positive sample (%)	No. of sample	Source of samples	No
80(20/25)	20(46.51)	88(22/25* 100)	22(36.66)	3(9.33)	22(34.37)	25	Cooling tower	1
48(12/25)	12(27.91)	60(15/25* 100)	15(25)	7(19.44)	18(28.12)	25	Tanks	2
40(10/25)	10(23.25)	56(14/25* 100)	14(23.33)	10(27.77)	15(23.43)	25	Tab water	3
4(1/25)	1(2.32)	36(9/25* 100)	9(15)	16(44.44)	9(14.06)	25	Swab from tab	4
172172/4=43	**43(100)**	**240(240/4=60)**	**60(100)**	**36(100)**	**64(100)**	**100**		**Total**

In one positive sample; two isolates may appear and in some samples, only one isolate appeared (frequency).

Two species of *Legionella* were isolated from water samples. The first was(60) isolates of *Legionella pneumophila*; and the second was (43) of *L. dumoffi*. The frequency of two species of *Legionella* in the cooling tower was more than other water samples, and the frequency of *Legionella pneumophila* was more than the frequency of *L. dumoffi*.

The frequency of *L. pneumophila* at pH_7 (88.3%) and this was more at pH_8 (60, 61.1 %) respectively. Whereas, the frequency at temperature 37°C (83.3%) was more than at 40°C and 45°C (73.3 and 63.37)% respectively. The current results showed also that the frequency of *L. pneumophila* was better at 0.3 ppm of R. chlorine when compared with 0.5 and 0.7 ppm of R. chloride. The frequency of *L. pneumophila* was high at 10 ppm of dissolved Oxygen and 3 ppm of Iron. Ag (silver) inhibited the growth of *L. pneumophila* at a concentration of 3ppm (table 2).

The results of the current study were incompatible with other studies. In Iran, only one isolate (2.9%) of *L. pneumophila* was isolated from water [11]. Whereas, in Saudi Arabia;the rate of *L. pneumophila* in water tanks was (8%), and most the isolates were grown better in pH_6 and pH_7; survived in temperature at 42°C and normal level of chlorine in water tanks. The other researches also isolated *L.dumoffi* (2%)[12].

The results of the present study are compatible with Al-Sulami*et al* [4]. *L. pneumophila* isolates were detected in 6 from 19 water stations in Basra governorate; the average of residual chlorine concentration was (0-1.03) mg/L.

Legionella pneumophila was emphasized for frequency in all water samples collected and it was the predominant species among other species affiliated with the *Legionella* spp. The spread of this species is evidence of the favourable environmental conditions, which increased the chance their presence in the samples, were indicated that these bacteria survive in temperatures between 40-42 °C, pH between 5.6-8.7 and high concentrations of chlorine ranged from 5.0-0.6 µg/ml [13].

Felice *et al*[14] isolated *L. pneumophila* from water

pools in Venezia Giulia, Italy. The prevalence of *L. pneumophila* was (82% of positive samples). In the Netherlands, 33.2% of water drinking water samples taking from buildings had *L. pneumophila*. This study was done to re-plan the drinking water management because *L. pneumophila* considered a dangerous bacterium which causing pneumonia and urinary tract infections [15]. 89 samples (43.6%) of 204 water samples (showerhead, taps in kitchens and tanks) had *L. pneumophila* in Kuwait, diagnosed with Real-Time Polymerase Chain Reaction[16]. Other studies showed that the prevalence of *L. pneumophila* in different water sources was (80%) in Mosul governorate/North of Iraq. The isolated *L. pneumophila* isolates were killed at 55°C for 30 min and 70°C for 5 min. Also, the isolates of bacteria were killed after exposure to UV light; 70% ethanol; 20% Isopropanol and 1% formalin [17]. Gauad*et al*. [18] determined the frequency of *L. pneumophila* in patients suffered from pneumonia and urinary tract infections using PCR technique. The percentage of *L. pneumophila* was 30% at hospitals in Baghdad city. The researchers suspected that the sources of *Legionella pneumophila* were drinking water or ventilation and cooling opening [18]. In Australia, the sources of *L. pneumophila* are shows, washing machines, swimming pools and lakes. The most isolates of *L. pneumophila* isolated from the water with temperature ranged from (>20 °C) to (<60 °C), and water containing free residual chlorine (<0.5 mg/L) [19-22].

The Relationship between Some Blood Components and Wool Production and Some of its Physical Traits in the Local Arabian Sheep

Hafetd Musa Ali AL-Taee[1], Rahman Hussein Hamza Al-Qasimi[2], Azhar Abdulabbas Jaffar Shareef[3]

[1]Assis. Prof., College of Food Sciences/Al-Qasim Green University/Iraq, [2]Lecturer College of Veterinary Medicine/ Al-Qasim Green University/Iraq, [3]Lecturer, Marshes Research Center/Thi-Qar University/Iraq

Abstract

The variation in the wool traits of Iraqi sheep is very large and is affected by non-genetic and genetic factors. The study was carried out in the fields of Al-Kafeel station in Karbala governorate on a sample consisting of 26 heads of local Arabian sheep to find out the relationship between wool production (raw wool weight, clean wool weight) and some of its physical traits (tuft length, fiber length, fiber diameter) with some Blood components (glucose, total protein, growth hormone, thyroxine hormone), as the results showed a positive significant regression of the raw and clean wool weight and the diameter of the fiber on the percentage of glucose in the blood and with a regression coefficient of 0.117, 0.023, and 0.224 respectively, while the two traits of the strand length and the length of the fiber did not record a significant regression on the level of glucose in the blood.

Keywords: *Arabian sheep, thyroxine hormone, fibrous diameter.*

Introduction

Iraqi sheep are one of the types of producing coarse wool that is used in the manufacture of carpets, floor furnishings and blankets, and the wool industry needs an integrated plan that begins first with improving its production in quantity and quality for the purposes of the carpet industry. The variation in the wool traits of Iraqi sheep is very large and is affected by non-genetic and genetic factors[1] the weight of the wool is the main indicator of wool production, and this in turn depends on a number of physical traits of wool, such as the ratio of clean wool, the length of the strand, the length of the fiber, the diameter of the fiber, the density and other traits, and its direct relationship with many internal, physiological and health factors that occur on the animal and therefore it is an economic traits. Important because it plays an influential role in the manufacturing process and its yields according to the types of wools produced from these animals [2]. The production of wool and its physical traits can be predicted through the association with chemical blood traits, some hormones and metabolic enzymes to improve the wool production trait through early selection. Where some researchers noticed a significant relationship between wool production and some of its traits with some blood components such as total protein, glucose and others [3]. From this standpoint, the aim of this study came to know the relationship between some blood components such as glucose, total protein, growth hormone, and thyroxin in a sample of local Arabian sheep for selection purposes and to improve wool production and traits at an early date to accelerate improvement programs.

Materials and Method

This study was carried out in the fields of Al-Kafeel station in Karbala governorate on a sample of 26 heads of local arabian sheep to find out the relationship between wool production (raw wool weight, clean wool weight) and some of its physical traits (tuft length, fiber length, fiber diameter) with some blood components (Glucose, total protein, growth hormone, thyroxine hormone).

Collection and analysis of blood samples: Blood samples were collected in clean and sterile plastic test tubes without anticoagulant and serum was isolated using a 3000 rpmcentrifuge. For the purpose of separating the blood from the rest of the components. the concentration of biochemical parameters was measured according to the method of work attached to each kit by the French company Biolabo SA in measuring the concentration of glucose and total protein using a Spectrophotometer. and it was adopted to measure the concentration of growth hormone and thyroxin hormone on the method described on the measuring kit provided by the American company Monobind Inc.

Measuring wool production and its physical traits: Sheep were sheared at the beginning of April and weighed directly to know the weight of the raw wool. Before shearing, a wool sample of 10×10 cm was taken from the area in the center of the right side of the animal (the last six ribs) as the best sampling area, according to[4]. After taking the weights of raw wool samples, these samples were washed in three containers on liquid soap to remove dirt and dirt with stirring and squeezing, and then dried at room temperature for 48 hours, then weighed the clean wool samples to extract the ratio of clean wool and clean wool weight as in the following formula:

Clean wool ratio = (clean sample weight/raw sample weight) × 100

Clean wool weight = Clean wool% × Raw wool Weight

The length of the tuft was measured after taking three tufts randomly from each sample and their lengths were measured using the usual ruler and without tensile or pulling, from the tuft base to the end of it. Special clips to be as tight and straight as possible to adjust their true length. The diameter of the fiber was measured using a German-born Primo microscope containing an Axiocam in the Histology and Anatomy Laboratory of the Faculty of Veterinary Medicine/Al-Qasim Green University, where ten fibers were taken from each sample and the general rate was extracted. The fiber was placed under the microscope and appears on the computer screen Connected to the microscope, a straight line is drawn between the ends of the fiber diameter using the mouse, and the diameter of the fiber appears in the micron [5].

Statistical Analysis: The program[6] was used in the statistical analysis to estimate the regression coefficients (trait of wool production on the studied blood trait) and the values of the parameter of determination, to be used in the selection and improvement programs.

Results and Discussion

The average weight of the raw and clean wool was 1.53, 0.97 kg, while the general averages of the traits were the length of the strand and the length of the fiber was 11.81, 14.54 cm and the diameter of the fiber 24.97 microns, which is similar to the results of [3,5]. As for the blood components, the mean of glucose was 66.57 mg/100 ml, total protein 5.68 g/100 ml, 9.83 ng/ml for growth hormone, and 31.74 nmol/liter for thyroxine (Table 1), and these rates are within the normal limits recorded by [7].

Table (1): General mean ± standard error for studied traits

Traits	Means	Standard error
Raw wool Weight (kg)	1.53	0.30
Clean wool Weight (kg)	0.97	0.21
Length of tuft (cm)	11.81	1.17
Length of fiber (cm)	14.54	1.16
Diameter of fiber (microns)	24.97	2.88
Glucose (mg/100mL)	66.57	6.13
Total protein (g/100ml)	5.68	0.98
Growth hormone (ng/ml)	9.83	1.19
Thyroxine hormone (nmol/L)	31.74	2.86

The current study shows that there is a positive significant regression at the level of P≤0.05 for the weight of the raw and clean wool and the diameter of the fiber on the percentage of glucose in the blood and with a gradient factor of 0.117, 0.023, 0.224, respectively, where the high level of glucose in the blood mg/100 ml gives an increase in the weight of the raw and clean cotton of 0.117 0.023 kg, respectively, and 0.224 microns in the diameter of the fiber, with a determination factor of 0.31, 0.25, and 0.20, respectively (Table 2). In agreement with [8,9], the two characteristics of tuft length and fibril length did not record a significant regression on the level of glucose in the blood.

Table (2): Regression of the production of studied wool traits on blood glucose

Traits	Regression coefficient b-	Straight line equation	Significance	Coefficient of determination -R^2
Raw wool Weight	0.171	y^ =0.821 +0.0117X	*	0.31
Clean wool Weight	0.032	y^ =0.838 +0.0023X	*	0.25
Length of tuft	0.0405	y^ =9.048 +0.0403X	NS	0.05
Length of fiber	0.0506	y^ =10.65 +0.0582X	NS	0.07
Diameter of fiber	0.223	y^ =10.27 +0.224X	*	0.2
Not significant : NS, (P≤0.05) : *				

It is evident from Table (3) that there is a highly significant positive regression at the level (P≤0.01) for the wool weight of the raw jelly over the total protein in the blood and with a gradient coefficient of 0.169, meaning that an increase in the level of total protein in the blood g/100 ml leads to an increase in the weight of the raw jute by 0.169 kg. With a determination factor of 0.39, the two trait of the clean wool weight and the length of the fiber also significantly decreased by (P (0.05) on the crude protein percentage and with a regression factor of 0.083 and 0.383 respectively, meaning that increasing the level of total protein in the blood g/100 ml leads to an increase in the clean wool weight by 0.083 Kg, with a determination factor of 0.29, an increase in fiber length by 0.383 cm, and a determination factor of 0.23. in the blood

Table (3) Regression of the production of studied wool recipes on total blood protein

Traits	Regression coefficient b-	Straight line equation	Significance	Coefficient of determination -R^2
Raw wool Weight	0.169	y^ =0.605 +0.169X	**	0.39
Clean wool Weight	0.083	y^ =0.501 +0.083X	*	0.2
Length of tuft	0.185	y^ =10.69 +0.185X	NS	0.02
Length of fiber	0.383	y^ =12.306 +0.383X	*	0.23
Diameter of fiber	0.836	y^ =20.422 +0.836X	NS	0.08
Not significant: NS, (P≤0.01) : **,(P≤0.05) : *				

Table (4) shows the presence of a negative significant regression at the level of P≤0.05 for the weight of the raw and clean wool at the level of growth hormone in the blood and with a regression factor of 0.016 - 0.048, respectively, meaning that an increase in the level of growth hormone in the blood ng/ml gives a decrease in the weight of the raw wool. And clean by 0.016 and 0.048 kg, respectively, with a determination factor of 0.34 and 0.19, respectively. as for the diameter of the fiber, it recorded a positive significant regression with the level of P≤0.05 on the growth hormone in the blood, with a regression factor of 0.673 and a determination factor of 0.503, meaning that the increase in the level of growth hormone ng/ml gives an increase the fibril diameter was 0.673 microns, while the strand length and fibril length did not record a significant decline in the level of growth hormone in the blood.

Table (4) Regression of the production of wool traits studied on the level of growth hormone

Traits	Regression coefficient b-	Straight line equation	Significance	Coefficient of determination-R^2
Raw wool Weight	-0.016	y^ =1.776 -0.016X	*	0.34
Clean wool Weight	-0.048	y^ =01.487 -0.048X	*	0.19
Length of tuft	0.064	y^ =11.12 +0.0095X	NS	0.02
Length of fiber	0.202	y^ =12.53 +0.202X	NS	0.03
Diameter of fiber	0.673	y^ =18.58 +0.673X	*	0.05
Not significant : NS, (P≤0.05) : *				

The current study did not show a significant regression for all the studied traits (raw wool weight, clean wool weight, length of tuft, fiber length, and fiber diameter) on the level of thyroxine hormone in the blood.

We conclude from this study the possibility of using some metabolic and hormonal compounds in the blood to accelerate the selection programs and improve some of the productive trait of the local Arabian sheep.

Abstract

Background: Diabetic cardiomyopathy is one of the serious complication of diabetes mellitus, with a silent development and it is often underestimated, Currently available diagnostic techniques are limited in their ability to identify patients who present with uncommon symptoms or silent myocardiopathy in its early stages.

Aim: To evaluate role of miRNA-378 compared to GLS as a sensitive biomarker for early detection of subclinical diabetic cardiomyopathy.

Method: The echocardiographic assessment for GLS was done for control group (H) and normotensive diabetic patients and these patients were divided into (CD) group without cardiomyopathy, and (M)group with cardiomyopathy diagnosed by negative GLS and positive GLS, respectively .Group (F) include Hypertensive and/or ischemic diabetic patients with overt heart failure.

Results: There is significant elevation in miR-378 Ct value between H in one side & other three diabetic gps. (CD, M, F) as presented in table (3-17) ($p< 0.05$). There is significant elevation in miR-378 Ct value in M than CD groups. There is significant elevation in Ct value in F than M gp. ($p=0.000$). In the ROC curve (AUC) was 0.965. The sensitivity and specificity were 0.978 and 0.646, respectively according to the chosen cut-off value.

Conclusion: This study showed that miRNA-378 could be regarded as a novel sensitive biomarker which could play a significant role for early detection of subclinical diabetic cardiomyopathy.

Keywords: *Diabetic cardiomyopathy, screening, GLS, sensitivity, miRNA-378.*

Introduction

Diabetic cardiomyopathy was first described by Rubler in 1972 [1,2]. The term describes several mechanisms involved in the pathogenesis of this entity including changes in myocardial structure and metabolism that are not directly attributed to other co-morbidities such as coronary artery disease (CAD) or hypertension. Left ventricular hypertrophy, myocardial lipotoxicity, increased oxidative stress, cell death from apoptosis, impaired contractile reserve, altered substrate utilization as free fatty acids (FFA), mitochondrial dysfunction and fibrosis are among the mechanisms involved with these changes in structure and metabolism contributing to the progression of heart failure [2]. Cardiac magnetic resonance (CMR) is the gold standard in the assessment of myocardial fibrosis given that T1 sequences separate normal from fibrotic tissue [3]. Nonetheless, CMR is not widely available, and it is time and cost consuming with longer and exhausting protocols. Speckle tracking echocardiography has been validated against magnetic

Assistant Lecturer, Al-Safwa University, Iraq
e-mail: saagzz2012@yahoo.com

resonance imaging[4,5]. Global longitudinal strain (GLS) is the simplest deformation parameter specified by Speckle tracking echocardiography and probably the closest to routine clinical application[6]. Quantitative assessment of myocardial function is now possible with this technique[7]. Routine use of Speckle tracking echocardiography in daily clinical practice is not cost-effective in this scenario and currently impractical for large-scale population screening. Therefore, assessment of individual risk factors becomes very important in clinical practice especially in primary care settings.More than half of patients with heart failure have preserved ejection fraction (HFpEF)[8]. In several studies, BNP proved to be a suboptimal screening test to detect pre-clinical LV dysfunction or LVH[9-11]. For all these reasons novel sensitive markers are needed. Although many substances have been suggested as biomarkers for DbCM, none have qualified for clinical use. Diagnosis and therapies are difficult because of a lack of specific biomarkers and imaging techniques. There is a need to anticipate the progression of heart failure in patients with diabetes and for that reason we propose a strategy of non-invasive analysis of inflammation-fibrosis LVD. The detection of appropriate biomarkers could potentially permit routine population-wide screening, allowing early diagnosis and anticipation of cardiac dysfunction,and stratify these subclinical cases[12,13]. MicroRNAs (miRNAs) are short noncoding RNAs that modify gene expression by regulating mRNA stability or translation during various disease processes. Each mRNA regulates expression of multiple genes. Dysregulated miRNAs are potentially involved in the pathogenesis of DbCM [14]. There are multiple miRNAs that have been implicated with the progression of disease. After release from the cell, these molecules remain stable in extracellular fluids and can be measured by quantitative polymerase chain reaction (qPCR)[15].Clinical studies have proposed peripheral blood microRNAs (miRNAs) as sensitive, specific and non-invasive biomarkers for the early monitoring of alterations in cardiac viability, structure, and function. Distinctive circulating miRNA signatures with clinical value have been described in various cardiomyopathies and type 2 diabetes and its related vascular complications [16,17].

Subjects, Materials and Method

Subjects: From May 2018 to April 2019, a total of 75 patients with DM2 and 25 control subjects who were aged 40–65 yr were prospectively enrolled from Diabetic Center, CCU, and Echo Unit in Merjan Medical City (M.M.C.) admitted as diagnosed cases of DM2 by expert physicians. Each 25 patients group has a definite characters as in table (1).

Table (1): Diagnostic criteria of study groups

CD group	Normotensive diabetic patients without cardiomyopathy diagnosed by negative strain echo study
M group	Normotensive diabetic patients with cardiomyopathy diagnosed by positive strain echo study
F group	Hypertensive and/or ischemic diabetic patients with heart failure diagnosed by conventional echo study
H group	Apparently healthy subjects with negative strain echo study

All were subjected to clinical examination including, heart rate and blood pressure. Further clinical details are shown in Supplementary Table (2).

Table (2): Clinical data for patients in all study groups and control subjects

Variables		Groups			
		CD Group	M Group	F Group	H Group
Total number (n)		25	25	25	25
Age/mean ± SD		52.76±6.3	53.04±6.2	58.44±5.9	50.88±8.1
Gender	Male	14	15	18	17
	Female	11	10	7	8
BMI (Kg/m^2)/mean ± SD		26.4±4.1	32.1±5.3	30.6±3.5	29.2±5.9
Family history of DM2	+ve	19	17	18	4
	-ve	6	8	7	21
HbA1c%		8.5±2.3	8.9±2.3	9.1±2.2	4.4±0.27

Method

Echocardiography: The gold standard biomarker of diagnosis was GLS% which was defined as the average longitudinal strain at end-systole in 18 segments. By regarding cut-off value of GLS = -18% according to (Islam E. Shehata et al[18] who reported that a GLS cutoff of<−18.1% was able to accurately "predict subclinical LV systolic dysfunction".

Strain echocardiography: Speckle tracking strain mode was selected on the echo-machine during apical 4, 2 and 3-chamber imaging and three consecutive cycles were recorded at a frame rate of 60 to 80 frame/sec. The LV is divided into 6 walls (inferoseptum, lateral, anterior, inferior, posterior and anteroseptal walls) every wall is divided into basal, mid and apical segments except the anteroseptum and posterior wall divided into basal and mid segments only, the global PSLS value for each participant were calculated as the average of values of the 16 segments[18].

Blood collection and Laboratory method: Venous blood was acquired by venipuncture without anticoagulant treatment. Samples were centrifuged and subsequently aliquoted and stored at −80 °C prior to analysis.For RNA isolation, an miRNeasy Mini Kit (Sigma/USA) was used to extract total RNA from 500 µl of serum. Reverse transcription (RT) was performed using a TaqMan MicroRNA Reverse Transcription Kit (Sigma/USA). The RT product was preamplified, and level of miR-378-5p (assay MIRAP00354) were measured by qPCR using a TaqMan miRNA assay (Applied Biosystems).miRNA species with CT value ≥35 were considered below the detection threshold. The serum miRNA expression levels in individual samples were determined by a TaqMan probe-based RT-qPCR on a 7300 Real-Time PCR Sequence Detection System (Applied Biosystems). Because U6 and 5S rRNA are degraded in serum samples and the lack of a consensus housekeeping miRNA for the RT-qPCR analysis of serum miRNAs, miRNA expression was normalized to serum volume [19]. For serum and exosome samples. Influence of haemolysis was discarded by analysing the Ct values of miR-23a and miR-451a[20].

Results and Discussion

The difference in miRNA-378 circulating level in different study groups: There is significant elevation in the Ct value of miR-378 with the progression of the diabetic cardiomyopathy as presented in table (4) indicating its down regulation as the disease progress. This result agreed with (Rui Guo et al) who classify miR-378 as anti-hypertrophic miRNAs as it is downregulated with the development of DbCM[21].

This result disagreed with (Sarah Costantino,) who stated that miR-378 is one of key initiators of apoptosis, were significantly over expressed in the diabetic heart and intensive glycemic control was unable to revert these changes [22]. The complex biology of miRNAs may also influence the respective findings. The miRNA profile of a given cell is highly specific to the stressor which it is exposed and suggests that miRNA expression in the human heart is dynamically regulated as a function of the pathophysiological context [23].

There is significant elevation in miR-378 Ct value between H & other three diabetic gps. (CD, M, F) as presented in table (5) $p< 0.05$; which represent its relevance to DM2. This result agreed with (Ivana Knezevic et al) who reported that in tissues such as fibroblasts and fetal hearts, where insulin-like growth factor receptor-1(IGF1R) levels are high, we found either absent or significantly low miR-378 levels, suggesting an inverse relationship between these two factors [24]. IGF-R are hybrid receptors which are more abundant when insulin receptors are down-regulated in response to the hyperinsulinemia as seen in insulin-resistant patients with DM2 as stated by Liam J. Murphy[25] Also it agreed with (Assmann et al[26]) who stated that it is down regulated with DM2. miR-378 down regulation relevance to DM2 approved by (Yong Zhang et al[27]) when they found that Tg mice had a significant overall increase in body O_2 consumption, CO_2 production, and energy expenditure.

The significant elevation in miR-378 Ct value in M than CD groups indicate its downregulation with the development of cardiomyopathy in its subclinical state as that miR-378 downregulated in case of hypertrophy development and oxidative stress increase [28]. These findings confirm the potential role of these modulators in identifying DbCM in relevance to their role in mitochondrial metabolism of cardiomyocyte via FoxO-1 as presented by (Puthanveetil, P.[29]) who stated that overexpression of FoxO1 mimics a hyperglycemic effect on vascular endothelium and also that hyperglycemia-induced endothelial dysfunction is mediated through FoxO1. miR-378 mimics reduced Akt phosphorylation also resulted in decreased phosphorylation of FoxO1, ultimately leading to FoxO1 activation. This effect was

also perceived in a H2O2-induced oxidative stress model in rat cardiomyocytes. So downregulation of miR-378 resulted in increased expression of FoxO1which resulted in mitochondrial dysfunction trigger cardiac cell death in diabetic heart disease.

There is significant elevation in Ct value in F than M gp. (p=0.000) which indicate more downregulation of miR-378 in F gp. than M gp.as presented in table (5). This lower expression may be due to different pathophysiological background related to hypertension & ischemia as concluded by (Jan Fiedler et al[30]) who published that presence of miR-378 attenuated ischemia-induced apoptosis by inhibiting caspase-3 expression in cardiac myocytes and blunted cardiac hypertrophy and dysfunction upon cardiac overload by targeting Ras signaling. So may be the ischemic hypertensive metabolic changes resulted in downregulation of miR-378.

Table (4): ANOVA–All Groups with Ct of miR-378

miRNA-378 as a screening marker: To evaluate the potential diagnostic value of miRNA-378, the ROC curve has been used. For cut-off value, values exceeding the cut-off are positive, while those below the cut-off are negative.

It is found that the area under the ROC curve (AUC) was 0.965 (Fig. 1). The sensitivity and specificity were 0.978 and 0.646, respectively. The cut-off Ct value was 20.06, it was appeared to have independent associations with the clinical end-points that are studied. As a blood-based marker, the miR-378 characteristics as highly sensitive may improve the screening values of DbCM. These results suggested that miR-378 may be highly sensitive and moderately specific enough to detect DbCM.

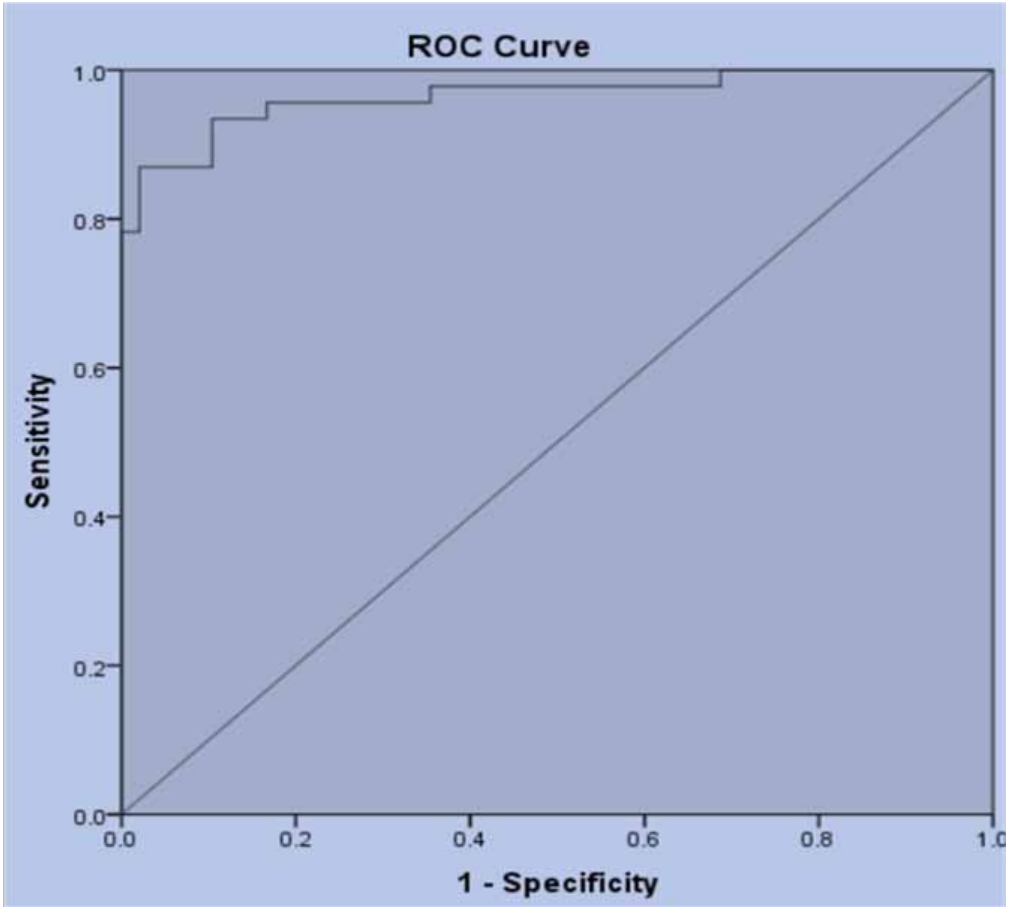

Figure (1): ROC curves for miRNA-378 Ct value in all study groups

The extremely high sensitivity (0.978) of miR-378 to identify DbCM patients from non-symptomatic diabetic individuals exceeded our most optimistic expectations.

These findings strengthen the clinical applicability of circulating miR-378 as a biomarker of diabetic cardiomyopathy in type 2 diabetes patients.

Conclusion

Serum miR-378 expression level can be regarded as a non-invasive tool to improve the detection, prediction, and monitoring of cardiac-related complications in the early stages of diabetes.

Abstract

Background: This study concentrated on evaluation the FBXW7 levels and other markers in T2DM patients related to the duration of metformin monotherapy and duration of T2DM.

Method: The current study includes 60 diabetic patients type II and30 control subjects. The groups of patients were subdivided in to two groups: (group I) (30) Newly diagnosed T2DM which also subdivided to two groups(> 1 year, and <1 year). Group II(30) T2DM (who were treated with metformin monotherapy) which also subdivided into two group (> 1 year and <1 year). In the present study FBXW7, FetuinA, pentraxin3, Nitric oxide and insulin were determined bythe enzyme linked immune sorbent assay (ELISA). Biochemical markers, fasting serum glucose, and lipide profile were determined through spectrophotometere technique in patients and control groups.

Result: The levelsof glucose, HbA1c and IR significantly affected byincrease the duration of diseaseWhile each of fbxw7, pentraxin 3,NO, and fetuin A not influenced by increase duration of disease. There was non-significant effect of metformin therapy duration on levels of Fbxw7,fetuinA, pentraxin3 and lipid profile. While IR showed significant decrease when the duration of treatment increase.

Conclusion: Fbxw7, fetuinA, pentraxin3 and NO arenot affected by long duration of therapy or by duration of disease while glucose, HbA1c, and IR are affected by increase duration of diseaseonly. Whereas insulin and IR are affected by both; duration of disease and therapy.

Keywords: *FBXW7, pentraxin3, nitric oxide, Type II diabetes, metformin, duration.*

Introduction

Among the most challenging health problems of the (21st century) is diabetes mellitus [1]. It is a chronic condition characterized by high levels of glucose in blood, resulting in significant damage to multiple organs including the heart,kidney,liver,eyes and vessels[2]. Weak glycemic regulation is known to be correlated substantially with a longer period of diabetes . Diabetes

e-mail: ikhlasmb_chem@csw.uobaghdad.edu.iq

is a progressive disease and as glucose levels increase, more medicinesare required to regulate it [3]. Metformin monotherapy is first treatment in diabetes type 2 patients which initiated when non-pharmacological therapy has failed to reach sufficient glycemic regulation[4]. Data from other studies showed that drug therapy of T2DM becomes more complex in longer duration of disease[5]. Fbxw7 is one of Fbox proteins and an important part of SCF E3 ligas complex that target proteins for thedegradation[6][7] Fbw7 protects against hyperglycemia, insulin resistance, and the glucose intolerance. Previous studies in obese patients showed hepatic down regulation of fbxw7[8].Fetuin A, named also α-2 Hermans-Schmid glycoprotein AHSG) is an acidic glycoprotein with molecular weight 64 KD [9]. It is belongs to proteases inhibitor cystatinesuperfamily[10]. Fetuin A is associated with high risk of diabetes, especially in people with high plasma glucose[11,12]. Studies to identify the markers for diabetes2 and its associated cardiovascular complications are important to control the disease, prevent the onset and progression of lethal complications at early stage[13].Pentraxin3are an acute phase protein superfamily which induce each of short pentraxin like c reactive protein (CRP) and long pentraxin like pentraxin3 (PTX3)[14]Actually, serum PTX3 level in patients with diabetes has been shown to be positively associated with atherosclerotic markers[15,16]. Nitric oxide (NO) is one of most common substances in the mammals which is considered as an internal gaseous free radical[17]. Previous studies suggested an alteration in serum NO levels in T2DM [18]. Some studies documented raise in NO rates in patients with diabetes while others reported lower in levels[19,20]. In the present study, weexamined the effectof *duration* of T2DM disease and duration Therapy on fbxw7 and other parameters.

Materials and Method

Serum sample from Ninety subjects were selected to perform this project, agerage between 37 to 69 years. They were divided in to 3 groups as follows: A control group consisted of 30 apparently healthy individuals. Group1 included 30 newly diagnosed (T2DM) without treatment, and group 2 included 30 patientson metformin monotherapy. Each groups of patients' sub divided into two group,> 1 year and <1 year. Bothgroups collected from National Diabetes Center for Treatment and Research at Al Mustansiriya University/Iraq.Patients with heart disease, liver disease, hypertension, kidney disease and smoker patients were excluded.

Blood samples were taken after overnight fasting. From each patient and control, 10 ml of blood was obtained. Two ml was dispensed in ethelendiaminetetracetic acid(EDTA) tube. This blood was used for HbA1c estimation. Serum that obtained was used in determination of other parameters. Serum fetuin A was estimated be quantitative sandwich enzyme immunoassay technique, using the kit fromcusabio, china. FBXW7 was determined by competitive enzyme immunoassay technique using the kit fromBiosource,USA. Enzymatic colorimetric method was used for serum glucose determination using the kit supplied by Randox UK.Insulin was determined by ELISA technique,using the kit supplied by Demeditec,Germany.Serum cholesterol and triglyceride were measured using the kit supplied by Spinreact,Spain. Whileserum HDL was determined by the kit supplied by Randox UK. Results were summarized as mean±SD. Statistical analysis program (SPSS 25) have been performed for analysisof the results. Student t-test has been used to identify the significant differences. Dendrogram have been used to identify the similarity between variables.

Results and Discussion

Effect of disease duration on diabetesrelated parameters: Analysis of baseline characteristics table 1, showed that glucose level, HbA1c and insulin resistance IR significantlyaffected by the duration of disease,glucose level and IR showed significant increase in group of patient with duration of disease > 1 year, also HbA1c show significant decrease in patient group > 1 year. While BMI,WHtR, AI,and lipid profile showed non-significant difference between patient groups.A relation between FBS and duration of diabetes in this study is in agreement with the results obtained by a previous study which reported that the incidence of severe hyperglycemia increased with age and duration [21].Long duration of Diabetes is known to be associated with poor control, possibly due to decreasesecretion of insulin over time due to B cell failure, which makes the response to diet alone or oral agents unlikely[22]. The levels of Fbxw7 significantly increase in newly diagnosed DM as compared to control but the increase was non-significant with prolong the duration of disease as shown in Table 2. This increase may be due to damage tissues caused by diabetes lead to decrease fbxw7 in tissues and increase secretion in blood. While each of pentraxin 3,NO, and fetuin A not influenced by increase duration of disease.

Group III (Newly diagnosed >1 year) represented by symbol (b)

Group II and group III represented by symbol (c).

Effect of duration of metformin therapy on diabetic-related parameters: Metformin is an antidiabetic medication that decreases peripheral resistance to insulin, increase peripheral uptake of glucose and reduces liver gluconeogenesis[23,24]. The results in the present study investigated the effects of duration of metformin therapy on fbxw7 and other diabetic- related parameters. The result in table 3 revealed that insulin and IR significantly influenced by duration of therapy and their levels decrease significantly by increase the duration of therapy, while there was non-significant difference in BMI, WHtR, AI,glucose, HbA1c, and lipid profile between groups of patient with treatment < 1 year and >1 year. Such finding are consistent with Delman Najim et al[25], which revealed metformin as an antidiabetic agent to decrease blood insulin levels and insulin resistance.

Also table 4 showed that the levels of Fbxw7, fetuin A, pentraxin3, and NO not influenced by the duration of therapy and there were non-significant difference in these parameters between patient groups themselves.

Table 3. Effect of duration of metform in treatment on parameters.

Color Change of Two Different Nano-Hybrid Resin Composite Materials after Staining and Bleaching. (An *in vitro* Study)

Zahraa Sabah Abdul Wahhab[1], Emad Farhan Alkhalidi[2]

[1]*B.D.S.,Conservative Dentistry Department/Dentistry College/Mosul University/Iraq,*
[2]*Assist. Prof. Dr. Ph.D. Oral Sciences,Conservative Dentistry Department/Dentistry College/Mosul University/Iraq*

Abstract

Purpose: To investigate the effects of staining and bleaching on color change of two different Nano-Hybrid resin composite materials.

Materials and Method: In total, 48 samples were fabricated (24 samples from each Nanotype). Samples of each composite group were sub-divided into three sub-groups (n=8). Samples of *Stain sub-groups* immersed in coffee solution for 48 hours at 37°C; in *Stain Bleach sub-groups*, samples were stored in coffee solution for 48 hours at 37°C then bleached with 30%H_2O_2; in *Bleach sub-groups*, samples were bleached with 30% H_2O_2. After that, color measurements were recorded again for each sub-group.

Results: After staining and bleaching, all sub-groups of both tested materials demonstrated clinically acceptable color change ($\Delta E<3.3$) with significant differences ($P<0.05$).

Conclusion: Color change of the two tested materials do not affected by staining and bleaching.

Keywords: *Composite resin, color change, staining, bleaching, hydrogen peroxide.*

Introduction

The esthetic success of resin composite restorationdepends greatly on its optical appearance and color match with the surrounding natural dentition; to render a restoration imperceptible, restoration materials should reproduce color of natural teeth and maintain long-term colorstability and resistance todiscoloration(1). Many parameters affect the colorstability of resinous materials liketype and volumeof resin material, size and typeof filler particles, and the coloring agents. Extrinsic discoloration can be caused by dietary and smoking habits, and adsorption or absorption of water-soluble stains within the composite organic matrix (2). Stains can be removed partially or totally by brushing with toothpastes, polishing and bleaching.; tooth bleaching is considered a conservative, easy and efficient methodforteeth whitening, and nowadays, tooth bleaching has become a routine treatment in common dental practice. Bleaching treatments can improve the color of discolored teeth and,at the same time, may yield color alterations of the existed composite restorations on teeth; also, composite restorations might undergo changes due to softening effectsof bleaching which ultimately affect their clinical durability (3).With the application of Nanotechnology to dental composites, Nano Hybrid composites have been used as restorative materials for their favorable mechanical properties. However, there is a controversy regarding their color stability after staining and bleaching. Therefore, this study investigated the color change of two Nanohybrid composite materials after staining by coffee and bleaching with 30% hydrogenperoxide. The null hypothesis suggested that staining and bleaching have no influence on color of both tested materials.

Materials and Method

Samples Fabrication: Twoesthetic Nano Hybridcomposite materials (Joyfil Nano hybrid composite, and Omnichroma resin based composite) were tested in this study (Table 1). In total, 48 disc samples (24 samples from each Nanotype), 5 mm in diameter and 2 mm in thickness, were fabricated using Polyurethane mold. The mold was placedon a transparentcelluloid matrixover a glass slab and filled with the tested material, then the surface of the mold was covered with anothermatrix and a glass slab.A 500g load was placedfor 30 seconds on the topof eachsampleto allow the excess material to leak out[4]. Load was then discontinued and thesamplewas light cured for 40 seconds using (LED light curing unit,Blue phase,Woodpecker, China) with 1000mW\cm^2 light intensity. Specimens were stored in artificial saliva at 37°C for 24 h[5]. Specimensof each composite material were divided intotwo majorgroups:

Gp1: Joyfil composite. (24 samples),

Gp2: Omnichroma composite. (24 samples).

Each composite group was further randomly subdivided into three sub-groups, each of which contained 16 samples (8 samples of each composite type) as follow:

- **Stainsub-groups:** Specimens were stained by incubating the samples in coffee solution at 37°C for 48 hours, then color change measurements were recorded.
- **Stain Bleach sub-groups:** Firstly, specimens stained in coffee solution for 48 hours then chemically bleached by 30% H_2O_2 gel; after that, color change measurements were recorded.
- **Bleach sub-groups:** Specimens were chemically bleached with 30% H_2O_2gel then color change measurements were recorded.

Table (1): Materials used in the study

Material name	Type	Composition	Manufacture
Joyfil	Nano Hybrid universal composite (Shade:A_2)	**Matrix:** BIS-GMA **Filler:** Non- agglomerated 7 nm nano-silica filler in size and aggregated schott glass/silicanano-cluster filler. Range is 0.7µm (74%w, 58.89%v)	3D Dental, USA
Omnichroma	Nano Hybrid composite (Universal shade)	**Matrix:** 1,6(methacryl ethyloxycarbonylamino), UDMA,TEGDMA. **Filler:** Spherical silica-zirconia filler. Ranging from 0.2-0.6micron (Mean particle size is 0.3µm (79%w, 68%v).	Tokuyama Dental,Japan
Dash Chairside whitening system	In-office chemical bleaching	30%Hydrogen peroxide	Philips,USA

Staining Method: Samples of Stain and Stain Bleach sub-groups of both composite materials were stained by coffee solution which was prepared by mixing (1.5g) of coffee powder (Nescafe Classic,Nestle,Indonesia) in 120 ml of boiling water according to manufacturer's instructions. Samples of both sub-groups were incubated in coffee solution for 48 hours at 37°C[1]. After staining, samples of Stain sub-groups were washed with distilled water and air-dried to be ready for recording color measurements, while samples of Stain Bleach sub-groups were rinsed with distilled water and incubated again in artificial saliva at 37°C until performing bleaching procedure.

Bleaching Procedure: Samples of Stain Bleach and Bleach sub-groups were chemically bleached with 30% H_2O_2 (Dash Chairside whitening system, Philips,USA). Bleaching gel was applied in an equal amount on the specimen for 45 minutes in three cycles, each cycle lasted 15 minutes according to manufacturer's instructions. After bleaching, samples were washed under running water for 1 minute to eliminate bleaching material remnants and then air-dried before color measurements were recorded.

Color measurement procedure: Color measurements were taken first for all sub-groups using VITA Easyshade®V Spectrophotometer and considered as initial data. After staining and bleaching procedures, color measurements were taken again for all samples

of both materials. VITA Easy shade is a simple click digital spectrophotometer that provides an instant shade read out. The measurements depend on the CIE L*a*b* (Commission International del'Eclairage) colorsystem toper form color change test [6]. Coloris measured in three coordinate dimensions: L* refersto lightness and its value range from (0) for perfect black to (100) for perfect white; the a*value is a measure of red-green axis, ($^{+}$a*=red,−a*=green); the b*value is a measure of yellow–blue axis, ($^{+}$b*=yellow,−b*=blue)[5]. Measurements were repeated for 3 times for each specimen and color change (ΔE) values were recorded according to the formula

$$\Delta E^* = \sqrt{(\Delta L^*) + (\Delta a^*) + (\Delta b^*)}$$

Statistical analysis: Normality test was used to check the normal distribution of the data and non-parametric tests were chosen since the data follow abnormal distribution. Friedman's test of related samples was used to test the significance of staining and bleaching at P<0.05 among and between the three sub-groups of both tested materials. Mann-Whitney U Test for independent samples was used to compare (ΔE) mean values between every two similar sub-groups of the two materials.

Results

The ΔE* values of all sub-groups were recorded and analyzed. According to many studies there are three different intervals for(ΔE): ΔE<1, imperceptible by human eye, 1<ΔE<3, recognizedonly by skilled persons; and ΔE ≥3.3, easily observed by human eye (clinically unacceptable) [1]. Mean and standard deviationof (ΔE) values are displayed in Table(2). All sub-groups of the twomaterials showed clinically acceptablecolorchange (ΔE<3.3). Friedman's test demonstrated significant differences (P<0.05) in colorchange among all sub-groups forboth tested materials as demonstrated in Table(3). As the sub-groups ofboth materials were significantly different, Friedman's test was used again tocompare each twopairsof sub-groups in both materials to indicate the difference between which sub-groups. In Joyfil composite sub-groups, there were significant differences (P<0.05) between Stain sub-group with both Stain Bleach and Bleach sub-groups. However, no significant difference (P>0.05) was seen between Stain Bleach and Bleach Joyfil sub-groups. For Omnichroma sub-groups, the results showed significant difference (P<0.05) between Stain Bleach and Bleachsub-groups. In contrast, there was no significant difference (P>0.05) between the other pairs of sub-groups as seen in Table(4). Mann-Whitney U Test used to compare the (ΔE) mean values of each two similar sub-groups of both composite materials, the results revealed significant differences (P<0.05) between Stain sub-groups and also between Bleach sub-groups. However, no significant difference (P>0.05) was seen between Stain Bleach sub-groups of both materials as seen in Table(5) and Figure(1).

Table (2): Mean and standard deviation of Color Change (ΔE) for all sub-groups of both tested materials

	Joyfil (ΔE)		Omnichroma (ΔE)	
Sub-groups	Mean	Std. Deviation	Mean	Std. Deviation
Stain	3.2	0.382324	2.03375	0.587001
Stain Bleach	1.64	0.822540	1.68750	0.339695
Bleach	2.04875	0.252102	2.47125	0.414882

Discussion

Resin composites are frequently used esthetic restorations in dentistry for their excellent aesthetic properties and adequate strength; composite restorative materials should mimic the appearance of natural teeth and one of main causes for replacement of restorations is when they reflect unacceptable color match with the surrounding dentitions[7]. For achieving desirable esthetics in dentistry, composite restorations should be able to maintain intrinsic color stability and resistance to surface staining. However, over time, composite restorations in the oral environment acquire external stains and develope internal discoloration which may be explained by the biphasic nature of the material (composed of matrix and fillers) that facilitates inclusion of external stains in its structure[8]. Coffee was selected in this study because it is frequently consumed beverages and it has a strong potential to stain teeth and restorative materials. Many studies have used coffee as a staining solution[1,3,7,9,10] and according to coffee manufacturers,

it requires an average of 15 minutes to drink a cup of coffee; coffee drinkers consume an average of 3.2 cups of coffee per day; therefore, specimens storage in coffee solution for 48 h equals an average of two months of coffee intake [9]. The findings of the present study showed that coffee induced clinically acceptablecolorchange (ΔE<3.3) in specimensof stain sub-groups for both tested materials with significant differences (P<0.05) between the two sub-groups. Discoloration by coffee attributed tobothabsorption and adsorptionofpolarcolorantsonto the surface of materials [7]. Another reason can be related to fluid uptake by resin composites as when composite can absorb water, so it can absorb othercoloredsolutions; the increase in fluid uptake was relatedtoincorporationof hydrophilic monomers in composite resin matrix. Bis-GMA and TEGDMA are hydrophilic monomers, but fluid uptake in Bis-GMA increased from 3 to 6%, while in TEGDMA it increased from 0 to 1%[2]. AlthoughpresenceofBis-GMA and TEGDMA in the twotested materials, their colorchange after staining was clinically acceptable. However, Omnichroma Stain sub-group was significantly less than Joyfil Stain-sub-group which can be attributed to the presenceof UDMA in its resin matrix which is more stain resistant than Bis-GMA with low water sorption and solubility. The acceptablecolorchange and low staining susceptibility after staining forboth tested materials can be explained by low resin content in the twomaterials (26% for Joyfil and 21% for Omnichroma). The findings of this study came in agreement with the results ofsome studies whoobtainedacceptablecolorchange (ΔE<3.3) of resin composites after staining with coffee [1,11]. In contrast, other studies found that coffee had induced severe clinically unacceptable staining (ΔE>3.3) of resin composite samples[3,7,9,10]. This discrepancy in results were probably related to differences in staining methodologies like the typeof immersionsolution and immersion time; also, the differences in chemical compositionof resin composite used may affect the results.

The interaction between bleaching agents and composite materials is of clinical significance and should be focused on; the bleaching system used in the current study was chemically activated with 30%H_2O_2. Hydrogen peroxide is a strong oxidizing agent that generates free radicals which have an extensive ability for diffusion and penetration the surface of composite materials then producing degradation of polymer network; thus, a resin composite with higher resin content is expected to be more pronounced to degradation and subsequently may undergo more colorchange [12].

Ideally, bleaching after staining would be considered good if (ΔE) values decreased and perfect if (ΔE) values are equal tozero because this means that the restorative materials have returned to their baseline colorbefore staining [1]. The findings ofthis study showed that bleaching after staining for both Joyfil and Omnichroma Stain Bleach sub-groups also gave acceptable color change (ΔE<3.3) with no significant differences (P>0.05) which refers to that bleaching following staining was effective in reducing the discoloration for both tested materials as the (ΔE) values after bleaching were decreased from the (ΔE)obtained after staining. These results came in accordance tosome studies that found bleaching treatments have decreased (ΔE) values of composite tested materials to a clinically acceptable level even after severe colorchange due to staining; they attributed this to superficial cleansing of the specimens by bleaching agents not due to internal bleaching[8,13]. In contrast with these results, others stated that bleaching after staining with a high concentration of H_2O_2 gave high and unacceptable color alteration (ΔE>3.3) for the tested materials and explained their results that high concentrations of H_2O_2 may cause chemical softening of restorative materials leading to more colorchange [1,14].

After bleaching, (ΔE) values ofboth tested materials for bleach sub-groups were also within the acceptable range (ΔE<3.3). However, the (ΔE) values of Omnichroma study samples was significantly higher (P<0.05) than that of Joyfil study samples. Omnichroma composite has average filler particles size of 0.3μm and lower amount of resin matrix (21%) by weight with different percentages of UDMA and TEGDMA, so it is expected to show low color change, but the results demonstrated the opposite. In contrast, Joyfil is Bis-GMA based resin material with average filler particles size of 0.7μm and resin matrix of (26%) by weight, but it showed less colorchange compared to Omnichroma resin composite. This finding may be explained by the differences of bond interfaces between resin matrix and fillers or the type of prepolymerized filler particles incorporated in these two materials that mayinfluence the effect of bleaching agent on them.

With respect to comparison of (ΔE) values among the three sub-groups in each tested material, the results showed significant difference among all sub-groups of the two tested material which may refer to that staining

and bleaching can change the color of tested samples but with acceptable levels.

Some limitations in this study can be pointed out like immersion of study samples in a single type of staining beverage; which can't reflect the actual staining potential of human dietary behavior. Also, this is an *in vitro* study, so it is impossible to directly mimicoral conditions because food and beverages ingestion is a dynamic process that doesn't allow sustained static retention of stain in the oral cavity.

Conclusion

1. The two Nano-Hybrid composite tested materials reacted similarly to staining and bleaching.
2. Staining by coffee and bleaching by 30%H_2O_2 didn't influence the color of both tested materials as ΔE values were within acceptable range ($\Delta E<3.3$).

The Effect of Interfering Waves Strategy in Developing Some Basic Volleyball Skills for Intermediate First Graders

Aujeed Madlool Abbas[1], Sattar Jaber Ashour[2], Bashar Akram Mohammed[2], Jabbar Ali Kathim[3]

[1]Lect., [2]Assist. Lect., [3]Assist. Prof., Al-Qasim Green University/College of Physical Education and Sports Sciences/ Iraq

Abstract

The research objectives to reveal the effect of using the interfering waves strategy in learning some basic skills in the game of volleyball (serve from the bottom facing, receiving the serve from the bottom, and preparing from the top) for the first intermediate students, the researchers used the experimental method, and the research sample consisted of (32 A student with (16) students in each group, and by lottery two groups were named to represent one of them the experimental group and the other the control group, and parity was achieved between the two groups in the variables (age, weight, and height) in addition to achieving parity between them in basic skills (under study), And the overlapping waves strategy was used with the experimental group players, but with the control group, the method was used by the trainer, and the implementation of the experiment took nine weeks with two educational units per week for each group of 18 educational units, and the time for one educational unit was (45) minutes, and the experiment started on 10/2/2018 until 1/15/2019.

The researchers used the following statistical method: the mean, standard deviation, simple correlation coefficient (Pearson), (t) test for two related means and two equal samples, and (t) test for two unrelated means and two equal samples. And after analyzing the data statistically, the researchers reached conclusions, the most important of which are:

1. The use of the overlapping waves strategy had a clear role in learning some basic skills (under study) for the experimental group players.
2. Take advantage of the overlapping waves strategy in physical education lessons for all school levels.

Keywords: *Interfering waves, activity of players; role of education; brain enhancement; strategy and skills.*

Introduction

Physical education is considered a science like the rest of the sciences. It uses the latest scientific method and method developed by scientists and researchers in a manner consistent with the nature of all society and its circumstances. This is what has contributed to the upgrading and development of physical education from scientific and educational institutions to the community. Sports activities are also an important means to achieve educational goals. This is because the academic subject is not a self-directed goal to be achieved. Rather, these activities have become means that the teacher can invest to reach through them to achieve the goals set according to the concept of modern education.[1]

It also aims to prepare students to reach their simple abilities to the highest possible level, and to work on their numbers and make them successful academics, and in order to achieve these goals it is necessary to deliver the teaching curriculum vocabulary to the learner according to scientific foundations and strategies commensurate

Corresponding Author:
Aujeed Madlool Abbas
Lect., Al-Qasim Green University/College of Physical Education and Sports Sciences/Iraq
e-mail: dr.aujeedmadlool@sport.uoqasim.edu.iq

with their abilities, including the interlocking waves strategy, which is one of the teaching strategies that It works to provide and guide students when studying a specific problem and to reach appropriate solutions in an organized manner that contributes to saving time and effort by the teacher, especially in difficult situations or aspects that require accuracy in their implementation.[2]

As none of the skills are more important than others, as they are the movements that the learner should implement, according to the circumstances required by the volleyball game, in order to reach positive results, economy, effort and delay in the state of fatigue. Through the foregoing, the importance of researching the variables that it studies is the strategy of overlapping waves and its role in developing social, psychological, skill and physical skills, which is a fundamental factor in achieving mental health, as well as its importance in learning basic skills in volleyball, to be an effective means for teachers to benefit from And, as well as the importance of the research sample, which is represented by middle first-grade students who represent future teachers, also the importance is embodied in preparing educational units according to the strategy of overlapping waves to depend on what the learner has of information or previous perceptions about the skill (to be learned) and employing it in the learning process for the new skill And according to his own capabilities and abilities, and it is done through educational units and in the form of cooperating groups, each of which has multiple duties and tasks, which provides a great opportunity in learning.[3]

The common strategy in learning basic skills in the game of volleyball is the strategy that follows the American approach that makes the teacher a decision-maker, imposing it on students not to exploit this strategy and diminish its advantages, but our current era is an era of cognitive prosperity and educational work, and this is what the researchers observed (Being a student, trainer, and teacher) while watching practical lectures of volleyball and personal interviews with some teachers of physical education and sports sciences, as teaching strategies must keep pace with this development, as working according to a strategy followed by the teacher determines the abilities and creative capabilities of the learner. Studies revealed that there are many teaching strategies, each of which has a special position in terms of goals and characteristics and has an effective role in learning basic skills as well as speeding up its learning. However, these strategies do not meet enough attention from most of the workers in the field of teaching in physical education and sports science,[4] as the lack of Reliance on modern educational strategies represents the problem of research, so the researchers decided to use a strategy Interlacing waves by preparing educational units according to this strategy in learning some basic skills in volleyball.

Research Objectives:

1. Knowing the effect of using the interfering waves strategy in investing the time of the physical education lesson for first intermediate students.
2. Knowing the effect of using the interfering waves strategy in learning some basic volleyball skills for first intermediate grade students
3. Identify the effect of educational units according to the strategy of overlapping waves in learning some basic skills in volleyball for students (experimental group) in pre and posttests.
4. Identify the effect preference in the post-tests between the two groups (control and experimental).

Research Hypotheses:

1. There is a positive effect for educational units according to the strategy of overlapping waves in learning some basic skills of volleyball for first intermediate grade students.
2. There is a preference in influencing the strategy of overlapping waves (the experimental group) and the strategy followed (the control group) in learning some basic skills of volleyball for students of the first intermediate grade and in favor of the strategy of overlapping waves (the experimental group).

Research Fields:

- The human field: The first intermediate grade students are (13-14) years old in Al- Irfan Intermediate School for Boys.
- Time range: 10/2/2018 - 1/15/2019.
- Spatial field: the internal and external arena of the school.

Research Methodology

The researchers used the experimental approach in the manner of equal groups, because it searches for the cause, and how it occurs, as it is defined as "what the researchers introduce from a variable in reality, and this is an intended change."[5]

And because the experimental method "represents the most honest approach to solving many practical problems in a scientific and theoretical manner,"[6] So researchers used to reach the desired results.

Research community and sample

Research community: The research community is determined from two students, whose number is (52) students, and whose average age ranges between (13-14) years.

The research sample: The research sample was chosen deliberately from the original research community, and by drawing lots, and by (32) students, representing 61.5% of the research community, as they were divided into two equal groups, and by (16) students per group, which is an appropriate percentage to represent a community Research is a real and honest representation.

The researchers excluded a number of sample individuals to achieve homogeneity, and the excluded ones are:

1. Exploratory experience personnel.
2. Older than (12-13) years.
3. Students are practicing the game.

Table 1. Shows the research population, its selected sample, and the percentage

Variables	N	Number of sample selected	Percentage
A sample pilot experiment	10	32Student	61.5%
The two students are the oldest year	5		
Students are practicing the game	5		

The homogeneity of the sample and the equivalence of the two research groups

Homogeneity of the sample: Before starting the implementation of the educational curriculum, the researchers resorted to checking the homogeneity of the research sample in the variables related to the morphological measurements (height, weight, age), and as shown in Table (2).

Table 2. Shows the homogeneity of the sample members in the variables (Age, Weight and Length)

Variables	Mean	SD	Median	Skewness	N
Age (in months)	133.5	133	3.8	0.44	32
Weight (Kg)	41.3	41	4.5	0.32	
Length (Cm)	143.13	143	6.18	0.05	

The two research groups are equivalent: Before starting the implementation of the educational curriculum, the researchers resorted to checking the parity of the two groups of research in the variables related to skill tests, which are the accuracy of performance of the skills under study, as shown in Table (3).

Table 3. Shows the equivalence of the experimental and control groups in accuracy tests for the skills of preparation and reception of serve and serve from the bottom facing the volleyball

Variables	Control group		Experimental group		(t) calculated*	Type of significance
	Mean	SD	Mean	SD		
Accuracy test preparation skill	2.05	0.43	2.06	0.37	1.09	No sig.
Test the accuracy of the serve reception skill	0.92	0.23	1.22	0.7	1.25	No sig.
Accuracy test of serve skill from below	1.57	0.53	1.40	0.35	1.05	No sig.

*The tabular score = (2.14) at the level of significance (0.05) and the degree of freedom (30).

Aids, devices and tools used in the research:

- Arab and foreign sources.
- Personal interviews.
- Auxiliary work team
- Tests and measurements
- Weight measuring device.
- A length measuring tape.
- (2) electronic stopwatch.
- Volleyball balls, number (8).
- Volleyball court.
- Colorful adhesive tape.

Tests used in the research: The selection of tests is one of the important steps in scientific research in order to measure the variables related to the research. Selection "is a set of exercises given to the individual aiming to define his abilities, aptitudes, or sufficiency".[7]

After the researchers, being a teacher, trainer, and player, were informed of most of the available resources related to his research, standardized tests were chosen to measure my skills (reception, serve from the bottom, preparation from the top, and serve from the bottom facing) with the volleyball of the age stage of the research sample. Because it suits the extent of validity and suitability for the age of the research sample.

Field research procedures

Pre-tests: The pre-tests were conducted for the research sample, after implementing two initial educational units, in which they included an explanation of the preparation skill through an explanation of the skill. Then the research sample applied this skill during the educational unit, and at the end of the unit, pre-tests for technical performance and accuracy of the preparation skill were conducted on Monday 10/10/2018.

The educational curriculum:

As for the vocabulary of the educational curriculum, it was as follows:

- The educational curriculum took (18) weeks divided into (3) weeks for the preparation skill, (3) weeks for the reception skill, (3) weeks for the serve skill from the bottom confrontation, and by two educational units per week, thus the total number of educational units for the preparation skill reached (6) Educational units for each skill, by two educational units per week, so the total number of educational curriculum units is (18) units for all skills.
- The teaching unit time (45) minutes.

Post tests: After completing (6) educational units in a period of (3) weeks to learn the skill of preparation, and with two educational units per week, the post tests were conducted for the two experimental groups, and under the same conditions that were in the pre-tests for this skill, and the post tests were conducted on Monday 5/11/2018.

Results and Discussions

Table 4. Shows the mean of mean, standard deviations, and the two values of (t) calculated and tabular between the pre and posttests of the skills under investigation (the control group)

Variables	Pretest		Posttest		(t) calculated	(t) tabulated	Type of significance
	Mean	SD	Mean	SD			
Transmitter from the bottom	17.93	2.18	25.2	3.26	4.76	2.13	Sig.
Preparation from above	9.6	2.64	19.13	2.31	3.04		Sig.
Receive the serve from the bottom	9.80	2.86	19.00	2.47	2.99		

Table 5. Shows the mean of mean, standard deviations, and the two values of (t) calculated and tabular between the pre and posttests of the skills under investigation (experimental group)

Variables	Pretest		Posttest		(t) calculated	(t) tabulated	Type of significance
	Mean	SD	Mean	SD			
Transmitter from the bottom	17	2.79	32.07	3.12	4.95	2.13	Sig.
Preparation from above	10.33	2.56	24.00	2.04	4.48		Sig.
Receive the serve from the bottom	10.26	2.54	24.47	2.82	3.36		

Table 6. Shows the mean of mean, standard deviations, and two t-values calculated and tabular between the post tests of the skills under investigation (experimental and control group)

Variables	Control group		Experimental group		(t) calculated	(t) tabulated	Type of significance
	Mean	SD	Mean	SD			
Transmitter from the bottom	25.2	3.26	32.07	3.12	2.69	2.04	Sig.
Preparation from above	19.13	2.31	24.00	2.04	2.82		Sig.
Receive the serve from the bottom	19.00	2.47	24.47	2.82	3.14		

The researchers attribute this development in the level of learning of the individuals of the research sample to the use of the strategy of overlapping waves, and this method has a different concept in the performance of the duty assigned to the learner, whereby it is to determine multiple levels of performance for the same assignment divided among all students in the manner of groups and stimulate competition between them and other groups as per His technical ability to perform, that is, at whatever level he begins to perform.[9]

The goal of the educational unit is to contain all students to perform the same duty to move in the process of dimensions to inclusion. Hence, the teacher's tasks are clear as he is responsible for implementing the educational and training process through the use of the interlocking wave strategy, which achieves the desired purpose of the educational, educational and social concept first by containing all students and at the same time working to develop the skills performance of two students in addition to the effectiveness of the educational units using this method that contributed to the development Physical and skillful capabilities.[10] Through the foregoing, the development of some basic skills in volleyball cannot be achieved in the desired manner except through the use of various educational method in the process of learning and training that achieve the desired purpose.[11]

The researchers attribute this superiority in performance to the strategy that was used in the application, as the researchers used the strategy of overlapping waves in education, since this strategy has advantages that can constitute a great addition in the learning and teaching process represented in transforming the educational material into multiple stages. The learner uses more than one sense in his learning, as well as investing the previous information in a way that serves and develops the learning process, and this increases the learning opportunities and the great ability to comprehend and comprehend and thus the possibility of applying the student to what he has learned to the fullest. "The best model for learning is to be through vision. Nevertheless, the stimulation and acceleration of learning will occur if the information is presented and processed by more than one sense".[12]

Conclusions

1. The strategy of overlapping waves used in the research has a positive effect, and the great and effective impact on the learning process and the development of some basic skills in volleyball.
2. Take advantage of the strategy of overlapping waves in physical education lessons for all academic levels of the proposed educational units, an active role in developing students 'level of learning some volleyball skills.
3. The interlocking wave strategy is the best in learning some basic skills in volleyball than the method used by the teacher with students and thus achieved the

goals and objectives that were set in order to achieve them.

4. The experimental group that learned according to the strategy of interfering waves was superior to the control group that used the strategy used in the post-test in learning some basic skills of volleyball for students.

Diagnostic Study of Some Microbiological Dacryocystitis with in Baghdad City Patients

Zena K. Khalil[1], Ala'a K. Husain[2], Saif S. Al-Kamil[3]

[1]Assist. Prof., [2]Optometrist, [3]Biologist, Al-Mansur Medical Technical Institute/Middle Technical University/Iraq

Abstract

The study was conducted from May -November 2019 among 114 dacryocystitis patients attending to ophthalmology department of Al-Yarmuk central hospital in Baghdad city. From of 114 patients with dacryocystitis, 90 (79%) patients had bacterial dacryocystitis, 24 (21%) with fungal dacryocystitis. According to the results 83(73%) recorded with chronic dacryocystitis and 31(27%) with acute dacryocystitis. The high percentage was bacterial dacryocystitis (32%), fungal dacryocystitis (38%) were at age of 74±0.3 y and the low percentage of bacterial was (11%) at 63±0.5 y and with fungal dacryocystitis (8%) at age of 42±0.3y. Patients with bacterial dacryocystitis had diabetes mellitus (56 %),arthritis and hypertension (28%,16 %) while the DM with fungal dacryocystitis (46%), arthritis, hypertension (38 %,16 %), *S.aureus* 23(26%), *S.epidermidis* 18 (20%),*Streptococcus spp.* 14 (16%), *Pseudomonas spp*. 11 (12%), *E. coli* 10 (11%), *Enterobacter spp* 9 (10%) finally *Proteus spp*. 5 (6%), while *Aspergillus flavus* represented 9 (37%) as causing fungal dacryocystitis, *Aspergillus fumigates* 7 (29%), *Aspergillus niger* 4 (17%)and *Candida spp* 4 (17%) . The antibiotic susceptibility tests revealed that *S. aureus* isolates were sensitive to Chloramphenicol (83%),. *S.epidermidis* isolates showed sensitivity to Gentamycin and Tetracycline (88%), *Streptococcus spp* showed the susceptibility to Erythromycin (93%), Ciprofloxacin (86%) respectively,*Pseudomonas spp* isolates considered highly sensitive to Tetracycline and Chloramphenicol (91%), *E.coli* isolates were also susceptible to Chloramphenicol (90%), *Enterobacter spp* were sensetive to Tetracycline and Gentamicin (78%),*Proteus spp* isolates seems sensitive to Chloramphenicol and Tetracycline (100%), *Aspergillus spp*. and *Candida spp*. isolates remain sensitive to Itraconazole, Voriconazole .

Keywords: *Dacryocystitis, bacterial and fungal infuctions, antibiotic susceptibility tests, Baghdad.*

Introduction

Dacryocystitis refers to lacrimal sac inflammation, which can be due to obstruction or blockage of normal tears drainage which leads to anathoe secondary infection and this is related to structural abnormality or eye disorders, and traumatic injury[1] . In acutetype of dacryocystitis which is basically caused by nasolacrimal duct abscess and maybe sometimes it is accompanied by dissemination of another infection as orbital cellulitis or thrombosis of the superior ophthalmic vein, and sometimes cavernous sinus, the patient presents with pain, redness, and edema around the lacrimal sac[2]. Diagnosis is depended on symptoms and signs and when pressure over the lacrimal sac causes reflux of mucoid material through the puncta. while the chronic form is associated with a mass under the medial canthal tendon and chronic conjunctivitis with epiphora. polymicrobial dacryocytitis were common and concurrently isolated from bacterial, fungal, and viral origin[3,4]. In general gram-positive bacteria were most common which were followed by gram-negative bacteria of both anaerobic and aerobic origin. most reports showed that fungal pathogens like *Fusarium spp.*, *Aspergillusspp*. and *Candida albicans* were the predominant ones isolated in dacroyocystitis patients with other bacterial pathogens[5,6]. It is important tomention that the clinical results, broad-spectrum antibiotic therapy till now are not effective to be as a diagnostic tool or a therapeutic

strategy. so, in each geographic area, total information about nearly the most microorganisms whic responsible for dacryocystitis is very necessary, as well as,the pattern of antibiotic susceptibility[7] .

The study was done to identify the microbial etiology and of dacryocystitis and investigate the patterns of antibiotic susceptibility among adult patients in Baghdad city.

Patients and Method

The study was conducted from May -November 2019 among 114 dacryocystitis diagnosed patients attending to ophthalmology department of Al-Yarmuk teaching hospital in Baghdad city .the information documented directly from the patients. data were collected using a structured and pre-tested questionnaire. Patients were examined by an ophthalmologist and specimens were collected from those patients presented dacryocystitis in their nasolacrimal dischargeunder sterile conditions. Specimens were collected with a sterile cottonswabs and inoculated on blood agar, MacConkey agar, Chocolate agar (Oxiod, Hampshire,UK) and Sabouraud agar (Biolife/Italy) .when incubation time is over, biochemical reaction teststhen done to confirm the species, API system was used (bio Merieux).[8]. For examination of hyphae and spore morphological microscopically, lacto phenol–stain was used[9].

Antibiotic Susceptibility: Antimicrobial susceptibility testing was performed following the disk diffusion technique according to the Clinical and Laboratory Standards Institute (CLSI), [10]. The following antibioticdisks were used; "Erythromycin (15 µg), Clarithromycin (15 µg), Chloramphenicol (30 µg), Clindamycin (2 µg), Tetracycline,(30 µg), Doxycycline (30 µg), Amikacin (30 µg), Gentamicin (10 µg), Ciprofloxacin (5 µg), Ceftriaxone (30 µg) supplied by (Oxiod,Hampshire, UK)".Strains of "*Staphylococcu*s (ATCC 25923), *E. coli* (ATCC25922) and *Pseudomonas aeruginosa* ATCC27853" were used as controls. CLSI M38-A2 BMD method foe antifungal drugs susceptibility[11]. The following antifungal agents:

"Voriconazole (1 µg), fluconazole (25 µg), itraconazole (10 µg), ketoconazole (50µg) metronidazole (50 µg), and amphotericin B(20 µg)". *Candida krusei* ATCC 6258 used as a controls,the results of susceptibility were recorded assensitive, intermediate and resistant.[12]

Statistical Analysis: Chi-square test and t-test used to analyze the findings as (P value <0.05) used to find the significance of difference[13] .

Results

From 114 patients with dacryocystitis, there were 90 (79%) patients of bacterial dacryocystitis and 24 (21%) with fungal dacryocystitis. Men with bacterial dacryocystitis were 52 (58%) and women 38 (42%), men diagnosed with fungal dacryocystitis were 17 (71%) and women 7 (29%) . According to the results 83(73%) recorded with chronic dacryocystitis and 31(27%) with acute dacryocystitis.

Patients with bacterial dacryocystitis (32%), fungal dacryocystitis (38%) were at the mean age of 74±0.3 y, lowest ratio with bacterial was (11%) at 63±0.5 y and with fungal dacryocystitis (8%) at age of 42±0.3y, the significant differences recorded between groups, table 1.

Most bacterial dacryocystitis patients were having DM(56%) and the others having arthritis or hypertension (28%,16%) while the DM with fungal dacryocystitis represented (46%) then arthritis or hypertension (38%,16%).

Table 1: Bacterial and fungal dacryocystitis related to the age groups

Age-years	Mean of±SD	N. of patients, bacterial dacryocystitis %	N. of patients, Fungal dacryocystitis %
15-25	20±0.5	21(23%)	6(25%)
26-36	31±0.7	13(14%)	2(8%)
37-47	42±0.3	18(20%)	2(8%)
58-68	63±0.5	10(11%)	5(21%)
69-79	74±0.3	28(32%)	9(38%)

p value (< .05)

S.aureus seemed as the most common cause of bacterial dacryocystitis 23(26%),, secondly *S.epidermidis* 18(20%), *Streptococcus spp*. 14(16%), *Pseudomonas spp*. 11 (12%), *Escherichia coli* 10(11%), *Enterobacter spp* 9(10%) and *Proteus spp*. 5(6%), and while *Aspergillusflavus* represented 9(37%), *Aspergillusfumigates* 7(29%), *Aspergillus niger* 4 (17%) and *Candida spp* 4(17%) were the main causative agents of fungal dacryocystiti as in table 2.

Table 2: Types of bacterial and fungal isolates from patients

Type of bacterial strain	Number %	Type of fungal strain	Number %
S.aureus	23(26%)	Aspergillus flavus	9(37%)
S.epidermidis	18(20%)	Aspergillus fumigatus	7(29%)
Streptococcus	14(16%)	Aspergillus niger	4(17%)
Pseudomonas	11(12%)	Candida	4(17%)
Escherichia coli	10(11%)		
Enterobacter spp	9(10%)		
Proteus spp	5(6%)		
Total	**90(100%)**	**Total**	**24(100%)**

The resent results revealed the susceptibility of *S. aureus* isolates to Chloramphenicol (83%) followed by Amikacin and Gentamycin (78%),. *S.epidermidis* isolates showed high susceptibility to Gentamycin and Tetracycline (88%) then Erythromycin and Amikacin (83%),*Streptococcus spp* showed the susceptibility to Erythromycin (93%), Ciprofloxacin (86%), table 3.

Table 3: Susceptibility patterns of *S.aureus, S.epidermidis* and *Streptococcus spp* isolates.

Antibiotics	*S.aureus* n = 23			*S.epidermidis* n = 18			*Streptococcus spp* n = 14		
	S	I	R	S	I	R	S	I	R
Chloramphenicol	19(83%)	1(4%)	3(13%)	15(83%)	1(6%)	2(11%)	11(79%)	2(14%)	1(7%)
Gentamycin	18(78%)	2(9%)	3(13%)	16(88%)	1(6%)	1(6%)	-	-	-
Tetracycline	17(74%)	2(9%)	4(17%)	16(88%)	1(6%)	1(6%)	11(79%)	1(7%)	2(14%)
Erythromycin	16(69%)	2(9%)	5(22%)	15(83%)	1(6%)	2(11%)	13(93%)	-	1(7%)
Amikacin	18(78%)	-	5(22%)	15(83%)	1(6%)	2(11%)	-	-	-
Doxycycline	16(69%)	2(9%)	5(22%)	11(61%)	2(11%)	5(28%)	-	-	-
Ciprofloxacin	-	-	-	-	-	-	12(86%)	1(7%)	1(7%)
Ceftriaxone	-	-	-	-	-	-	10(71%)	1(7%)	3(22%)

Pseudomonas spp isolates were high susceptible to Tetracycline and Chloramphenicol (91%), Ciprofloxacin (82%) and Amikacin and Gentamycin (73%) each of them, *E.coli* isolates reported susceptible for Cloramphenicol (90%), Ciprofloxacin (80%) but they were resistant to Amikacin and Tetracycline (80%,90%).

Enterobacter spp remained susceptible to each of Tetracycline and Gentamicin (78%), Amikacin (67%%), *Proteus spp* confirmed susceptible to Cloramphenicol and Tetracycline (100%), Ciprofloxacin and Ceftriaxone (80%), table 4.

Table 4: Susceptibility of *Pseudomonas spp, Escherichia* coli and *Enterobacter spp*.

Antibiotic	*Pseudomonas spp.* n = 11			*Escherichia coli* n = 10			*Enterobacter spp* n = 9			Proteus spp n = 5		
	S	I	R	S	I	R	S	I	R	S	I	R
Chloramphenicol	10(91%)	1(9%)	-	9(90%)	1(10%)	-	5(56%)	2(22%)	2(22%)	5(100%)	-	-

Itraconazole	18(90%)	1(5%)	1(5%)	4(100%)	-	-
Voriconazole	16(80%)	2(10%)	2(10%)	3(75%)	1(25%)	-

Discussion

The study revealed that patients with bacterial dacryosistitis were (79%) and (21%) were having fungal dacryocystitis, men represented the highest levels (58%), (71%) respectively, the highest ratio of males related to microbial dacryocystitis as a compression to females has been recorded in some other studies[14,15]. Acute and chronic dacryocystitis forms were found in the study, but (73%) were chronic, as a same as found in many previous studies that explained the role of chronic structural disorders of the tears drainage[16]. Patients with microbial dacryosistitis at mean age of 74±0.3 were hight and started to decrease, these fining are disagreed to other study in Baghdad, this may related to selecting of the known causes of infection[17] . Bacterial dacryosistitis patients, recorded with DM were (56%) and the rest patients recorded with arthritis and increase of blood pressure (28%,16%) while the diabetic with fungal dacryosistitis were (46%), arthritis then hypertension (38%,16%), these findings disagreed with other studies depending on the age and some other chronic disease may be due to health style including food as well as environmental changes[18,19] . *S.aureus*, the common cause of dacryosistitis 23(26%), *S.epidermidis* 18 (20%) in the second degree then *Streptococcus spp*. 14(16%), *Pseudomonas spp*. 11 (12%), *Escherichia coli* 10 (11%), *Enterobacter spp* 9(10%) and *Proteus spp*. 5(6%), the main causes of keratitis were *Aspergillus flavus* 9(37%), *Aspergillusfumigates* 7(29%), *Aspergillus niger* 4 (17%),*Candida spp* 4(17%), the results agreed to other studies in Baghdad[20,21]. Other study mentioned that Pseudomonas spp. represented most of bacterial isolates, as well as,Staphylococcus spp. while the fungal causes detected in 15 cases.[22] these result scan be changed depending on the climatic disturbance conditions or socioeconomic parameters[23] . G+ and G- bacterial isolates were almost susceptible to the antibiotics in the study and these findings were similar to different other studies[24,25] fungal isolates appeared its high susceptibility to the common antifungal drugs, *Aspergillus spp*, were clearly had asensitive reactions to Itraconazole, Voriconazole. *Candida* recorded sensitive

when tested, these seems to have a great match with some results done[26].

Conclusions

Among dacryocystitis patients, *S. aureus*came in the highest ratio of g+ bacterial isolates, *S.epidermids* secondly while g-*Pseudomonas spp* looked very dominant. *Aspergillus spp*was the highest among the fungus then *Candida spp*. All of gram + and gram -, as well as the fungus seems highly susceptible for the different antibiotics discs,so,we recommend the importance of antimicrobial susceptibility testing which must be done as a routine clinical, diagnostic practices method to manage the resistance patterns of microbial infections a long time hoping to completethe treatment strategies supporting and continuous personal educations to control the improper self-medication.

The Effect of the Physical and Artistic Education Lesson Through Play and Art in Developing Some Motor Abilities and Reducing Mobility for Pupils in the Fifth Grade of Primary School of the Primary Stage

Aujeed Madlool Abbas[1], Nawfal Shamkhi Naji[2], Haider Sami Muhammad[3], Jabbar Ali Kathim[4]

[1]Lect., [2]B.Sc. Researcher, [3]Assist. Lect., [4]Assist. Prof., Al-Qasim Green University/College of Physical Education and Sports Sciences/Iraq

Abstract

The research objectives to reveal the effect of the physical and artistic education lesson during play and art to develop some motor abilities and reduce hyperkinetic among fifth grade pupils. The researchers used the experimental approach, and the research sample consisted of (66) students and (10) students in each group, and about By drawing lots, two groups were named to represent one of them the experimental group and the other the control group, and parity was achieved between the two groups in the variables (age, weight, and height) as well as achieving parity between them in terms of motor abilities (under study) and their hypermobility, and playing and practicing technical drawings with Pupils of the experimental group As for the control group, the method used by the teacher was used, and the implementation of the experiment took nine weeks with two educational units per week for each group of 18 educational units, and the time of one educational unit reached (45) minutes, and the implementation of the experiment was started. On Sunday, 10/2/2018, until Thursday, January 14, 2019.

After analyzing the data statistically, the researchers reached the following two conclusions:

1. Learning by playing and art during the physical and artistic education lesson had a clear role in developing some of the experimental group's motor abilities.
2. The learning style by playing and art collectively led to the reduction of hyperactivity and distraction, and the formation of good relationships between them.

Keywords: *Physical, artistic, health; brain development; primary schools; and motor abilities.*

Introduction

The primary stage is one of the important developmental inputs in the development of human resources. When the child enrolls in middle school, his primary concerns are learning and developing some motor, physical and skill abilities.

Corresponding Author:
Dr. Aujeed Madlool Abbas
Lect., Al-Qasim Green University/College of Physical Education and Sports Sciences/Iraq
e-mail: dr.aujeedmadlool@sport.uoqasim.edu.iq

As the primary stage is an important stage of a person's life, it is the stage of basic learning, and it requires dealing with it by physical processes and not with abstract matter. Learning goes through a stage of development imposed by the nature of the age and depends on the useful function of what we learn in the sense that we transform the facts of science into practical practices and not be satisfied with practices Based on memorization, indoctrination, or the use of some pictures, and in order to reach the child during the educational process to such advanced stages of mental, motor and scientific development, it is necessary to use interesting educational method that stimulate their preferences and desires and encourage them to learn

and their learning style through play and art. Primary school pupils need to have a good and sound mental, psychological and physical development,[1] and this need is related to satisfying other needs, as the child's mobility, psychological, social and intellectual capacity does not grow, and his scientific knowledge and experiences do not increase unless his motor development is sound through playing and drawing in the physical and artistic education lesson. [2]

And because the style of learning by playing and art through my studies of sports and art depends mainly on the ability to creativity and show technical and sports skills, because they are a lesson in which the students feel happiness, freedom of movement and expressing their happiness through drawing in colors, installing manual artworks, discharging excess energy and reducing aggressive behavior. The style of learning by playing and art is one of the important method that it is preferable to use with this age group, especially if this method is combined or combined with the development of motor abilities and the reduction of their hyperkinetic, especially since the learning process through some games and the participation of students with collective artistic work that gives the lesson a kind of Excitement and excitement, and thus learning becomes more acceptable while ensuring the active participation of all children, and from here came the importance of research through the use of learning by playing and art through my studies of physical and technical education, and thus linking with the development of motor abilities and reducing their hyperkinetic that students need at this age.[3]

Through the researchers following up on the behavior of children in some school as they are teachers of technical and sports education, they found a clear weakness in the performance of motor abilities, excessive random behavior, and aggressive and chaotic behavior in a group of them as a result of their distinctive movement behavior with excessive activity and many movements, and this is called excessive movement activity, which is a behavioral state.[4]

Research Objectives:

1. Recognizing the effect of learning by playing and art on reducing hyperactivity among fifth grade primary students.
2. Recognizing the effect of learning by playing and art on developing motor abilities among fifth grade students

Research Hypotheses:

1. There is an effect of learning by playing, learning by playing and art, in reducing hyperkinetic among fifth-grade students.
2. There are significant differences between the pre and posttests in favor of the post tests for the two research groups.

Research Fields:

- The human field: Fifth grade pupils of primary school in Babil Governorate/Abi Tamam Primary School for Boys.
- Time range: for the period from 10/2/2018 to 1/15/2019
- Spatial field: the courtyards and halls of Abi Tammam Primary School, Al-Hashemiya District/ Babel Governorate.

Research methodology and field procedures:

Research Methodology:

The process of researchers 'selection of the methodology used in their research, which must suit the nature of the problem to be studied, is of great importance in reaching a solution to that problem.

Research community and sample

Research Community: Determining the research community is one of the important steps and stages in the process of conducting the research.[5] Researchers can deal with the entire community with the research if this community falls within the limits of its capabilities and capabilities.[6] The research community is defined as "all of the individuals, events, or things who are the subject of the research problem" [7] The research community included primary school pupils (fifth grade primary) of (11-12) years of age from boys only, their number reached (66) students, and in the Abi Tamam Primary School in the Hashemite District Center, Babil Governorate.

Research Samples: As it is known that the sample is that part of the society that the researchers want to conduct its study on, "it must be representative of all the vocabulary of that community and that this representation is supposed to be honest" .[8]

Accordingly, the research samples were divided into:

The first exploratory sample: It is the sample through which the level of understanding of the sample members and their comprehension of the paragraphs of the hyperkinetic scale was identified, as well as ensuring the possibility of carrying out the tests for the most important motor abilities, and this sample consisted of (25) students.

The second exploratory sample: It is the sample through which it was ascertained that the curriculum prepared by the researchers could be implemented. This sample consisted of (15) students.

Application sample (experimental group and control group): The researchers selected members of the application sample from Abi Tammam Primary School, and this sample consisted of two divisions of the fifth grade of primary school, as all students of these two classes did not participate in the main experiment to prepare the scale, as well as in the exploratory experiment of the curriculum prepared by the researchers, and it was excluded The students who failed and selected pupils at the age of (11-12) years, and the students who could not participate in the lesson for medical reasons and because of their ages older than (12) years and their number (6) were excluded, as the total sample amounted to (20) students and by (10) students From each division, then after drawing a lot between them, one of the people was chosen to be an experimental group and the other a control group.

Table 1. Shows the homogeneity of the sample in the variables of age, height and weight

Variables	Units	Mean	Median	SD	Skewness
Age	Month	124.5	124	3.61	0.42
Length	Cm	139.05	139	4.22	0.04
Weight	Kg	36.057	36	5.71	0.03

It can be seen from Table (2) that the value of the skewness coefficient ranges between (0.03) to (0.42) and it is confined to (± 1). This means that the sample is normally distributed, indicating its homogeneity.

Table 2. Shows the equivalence of the control and experimental groups in the pre-tests for the research variables

Variables	Experimental group		Control group		(t) value	Statistical significance
	Mean	SD	Mean	SD		
Moving balance	8.34	1.522	8.6	1.3	0.48	No sig.
Agility	23.9	0.96	21.6	1.08	0.78	No sig.
Compatibility	15.49	1.23	15.6	1.09	0.34	No sig.
Hyperkinetic	34.75	6.32	35.25	6.34	0.14	No sig.

Determine the tests: The selection and determination of tests is not an easy process, as the test must be based on accurate scientific foundations in order to achieve the purpose for which it was established, as the test is "an important means of measurement and it is a tactic of measurement".[9] After the researchers looked at a number of scientific sources, letters, dissertations and available scientific research related to the study of the research and as a teacher and trainer in the field of sports, a number of tests for football skills were collected, after which some tests were chosen on the experimental and control group.

Research procedures on sample application

Pre-tests: Pre-tests were conducted to measure the kinetic satisfaction of the experimental group of (10) students on Wednesday, 10/12/2018 at nine o'clock in the morning at the yard of the Abi Tammam Primary School in the Abi Tamam Primary School, and pre-tests were also conducted to measure the hyperkinetic of the control group of its number. (10) Students on Thursday 10/13/2018 at ten in the morning in one of the classrooms at Abi Tamam Primary School.

The main experience: The main experiment was started on Sunday 10/16/2018 until Sunday 10/1/2019, when the two educational approaches were applied according to the different educational method for each curriculum and the same capabilities under consideration, and the two groups were performing their work as follows:

Post tests: After completing the main experiment, and for the purpose of determining the level reached by the research sample with its two groups (experimental and control) in motor satisfaction and the basic skills under investigation, and to determine the extent to which the two groups have benefited from the application of (play, art, and the method used), post-tests of the two groups were conducted for a period of 13/1/2019 to 1/14/2019, and the researchers made sure that the conditions are similar to the pre-tests in terms of location, time, and the presence of the assistant work team. The same steps were used in the pre-test in the method of measuring the achievement of students in each test.

Results and Discussions

Table 3. Shows the average of means, standard deviations, and two t-values calculated and tabular between the pre and post tests for the skills under investigation (experimental group)

Variables	Pretest		Posttest		(t) calculated	(t) tabulated	Indication of differences
	Mean	SD	Mean	SD			
Moving balance	8.34	1.522	5.91	0.90	3.32	2.26	Sig.
Agility	23.9	0.96	19.23	0.91	6.72		Sig.
Compatibility	15.49	1.23	10.75	1.36	8.12		
Hyperkinetic	34.75	6.32	25.13	3.18	5.95		

Table 4. Shows the average of the mean, standard deviations, and two t-values calculated and tabular between the pre and posttests of the skills under investigation (the control group)

Variables	Pretest		Posttest		(t) calculated	(t) tabulated	Indication of differences
	Mean	SD	Mean	SD			
Moving balance	8.6	1.3	6.9	1.3	2.5	2.26	Sig.
Agility	21.6	1.08	19.7	1.7	3.01		Sig.
Compatibility	15.6	1.09	12.3	1.2	6.4		
Hyperkinetic	35.25	6.34	32.88	5.94	1.78		

Table 5. Shows the average of means, standard deviations, and two t-values calculated and tabular between the post tests of the skills under investigation (experimental and control group)

Variables	Control group		Experimental group		(t) calculated	(t) tabulated	Indication of differences
	Mean	SD	Mean	SD

Agility	6.9	1.3	19.23	0.91	6.72		Sig.
Compatibility	19.7	1.7	10.75	1.36	2.72		
Hyperkinetic	12.3	1.2	25.13	3.18	3.05		

The experimental group in improving performance and motor abilities, the researcher attributes it to the effect of the method applied by the pupils of the experimental group, and the various physical, movement and artistic small games it contained through drawing and handicrafts that contributed to improving the physical, motor, mental, mental and social abilities through the collective participation of the pupils. Suitable for their abilities and capabilities, and I took into consideration the peculiarity of this age stage, as (Kurt Maynell, 1987) indicates that this age stage is the best stage for motor learning, especially the ability to act in terms of motor activity and purposeful motor control, as the locomotors transport improves and becomes good especially for

the use of the trunk. And large kinematic fluidity. As the physical and artistic education lesson focused on games and artistic participations that suit their motor, artistic, mental and physical abilities,[10] which in turn gave the pupils the ability to learn better, as the sources indicate, "An individual who has a level of physical and movement abilities will help to develop basic skills." [11]

The biological development of the student at this age stage has an important role in developing many skills and physical and motor qualities, the most important characteristic of this age stage is learning the movements that are characterized by balance, such as games of time, running, alignment, balance, agility, flexibility, etc. Of the abilities and physical and movement characteristics and swimming, which is an extension of the basic movements that the child has learned and mastered in earlier stages, and therefore the learning capacity of the child is high and accurate and has a high movement compatibility that reaches the highest possible in many sporting activities .[12]

The researcher attributes the reason for this to the fact that playing with games and artistic participations greatly reduced the excessive motor activity of its members, as the existence of an effective educational approach to the method of linking play and art for late primary school students has an effective positive effect in reducing the undesirable behavior in which it is motor activity Plus, as the curriculum relied mainly on drawing the child's attention to something he loves and pushing him to patience to modify his behavior, gradually and by using several method, including positive support for appropriate as well as material behavior, taking into account the importance of the child's nature, and that he cannot settle and calm for a long time. One of the method of behavioral therapy is positive reinforcement, which is "the provision of material and moral reinforcements for the child's positive behavior, through symbolic reinforcements, and then these symbolic reinforcements are replaced by concrete reinforces such as gifts."[13]

Conclusions

1. Learning by playing through the study of physical and artistic education made the research sample reach the best in the physical, skill, motor and moral levels, as the results indicated that many developments occurred in the abilities of students, and this is what fulfills the hypothesis of the research.
2. Achieving very high results in the tests under investigation.
3. The learning style through play and art collectively led to the reduction of hyperactivity and distraction, and the formation of good relationships between them.
4. Improved motor abilities after playing games and practicing technical drawings for formations due to their reliance on technical, collective, movement and sports aspects.

Molecular Study of Genetic Diversity in *Escherichia coli* Isolated from Tap Water in Baquba

Noor Jameel Allhaby[1], Hadi Rahman Rasheed Al-Taai[2]

[1]Postgraduate, [2]Prof. Dr., College of Science, Diyala University, Iraq

Abstract

One hundred and ten samples of the tap water in Baquba city were collection .Ten isolates were obtained. The results of the sensitivity test showed that 10 isolates were multidrug, 10 isolates exhibited moderate resistance ranging from 5-8 antagonists. Through the use of the RAPD-PCR profiling system, the vast majority of *Escherichia coli* strains under study have large genomes and high virulence factors by belonging to group A2. Results of genetic profiling using the ERIC- PCR and BOX-PCR system showed several groups of isolates were identified as having a genetic variation and B2 group was given the highest proportion of ERIC- PCR system,70% in ERIC While A2 group was given the highest proportion of BOX- PCR system,40% in the BOX indicating that there is a negative spread The present study indicates that there is a correlation between taxonomic systems was evident by the distribution of isolates in each pattern and group.

Keywords: *E. coli, ERIC-PCR, BOX-PCR, RAPD–PCR.*

Introduction

Escherichia coli is a gram-negative bacteria belonging to the Enterobacteriaceae family, short bacilli, facultative anaerobic[(1)]. *E. coli* is a major component of the human normal intestinal flora. Among the intestinal pathogens[(2)]. There are several virulence factors that contribute to *E. coli* pathogenicity, such as enterotoxins, endotoxin and biofilm formation[(3)]. These bacterial strains are a potential reservoir for antimicrobial resistance genes[(4)]. The widespread development of resistance to several different antibiotics is generally as a result of lateral or horizontal gene transfer. Many studies have demonstrated that plasmid transfer between bacteria occurs in diverse environments[(5)]. *E coli* bacteria are used as biomarkers such as their use as a source of faecal contamination in environmental samples. Where the presence of these strains (whose habitat is the intestines of humans and animals) in the water indicates fecal pollution resulting from humans or animals, and thus environmental pollution.[(6;7)]. PCR fingerprinting method like enterobacterial repetitive intergenic consensus (ERIC- PCR) and BOX-PCR has been extensively used to study genetic relationship as they have discriminatory capability in differentiating different genera of bacteria[(8)].

The aim of this study is study virulence factors and genetic diversity for *E. coli* bactera isolates from environmental sources (water).

Materials and Method

E. coli **sample collection and identification:** In this study, ten isolates of *E. coli* were isolated from 110 tap water sample at the Baquba city,during October-December 2019.

Take known volume (30 mL) of water samples collected from tap water in Baquba city, cultured on Maconkey broth medium to ensure that the samples are contaminated with Gram-negative bacteria, and then cultured on contaminated samples on Maconkey agar plates, and then cultured on Eosin methylene blue agar plates for isolation of enteric bacteria. Gram stain and other biochemical tests were used such as IMViC Tests,Urea and Kligler Iron Agar.[(9)].

Susceptibility test of antibacterial agents: Susceptibility of all the isolates to different antibiotics was determined by the disc diffusion method as recommended by the Clinical and Laboratory Standards Institute (CLSI) (10). The antibiotic discs used in this study were (Tetracycline (30µg), Imipenem (10µg), Doxycycline (30µg), Aztreonam (30µg), Levofloxacin (5µg), Cefuroxime (30µg), Trimethoprim-sulfamethoxazole (1.25/23.75µg), Azithromycin (15µg), Cefoxitin (30µg), Ticarcillin-clavulanate (75/10µg), Cefpodoxime (10µg). Ampicillin-sulbactam (10/10µg)) Each antibiotic concentration was applied on the surface of Muller Hinton agar plates inoculated with E. coli isolates and incubated at 37°C for 24 h.

Biofilm formation detection using Micro Titer Plate method (MTP): The bacterial isolates were cultured on nutrient broth for 18- 24 hr at 37°C aerobically. About 200 µL of the bacterial suspensions were transferred into polystyrene plates containing 96 wells and a broth without bacterial inoculum was used as a negative control. The plate was incubated for 24 hr. The bacterial suspensions then removed and each well was washed three times with sterile saline solution (0.9% NaCl). The cells stuck on the walls were fixed with 200 µL of methanol for 10-15 minutes. The methanol was removed, the plates were left at room temperature to dry and they were stained with 200 µL of crystal violet 0.5% for 10-15 minutes. The plates then washed with distilled water 2-3 times and dried at room temperature. The absorbency was taken in an ELISA reader at wavelength of 630 nm, [11]. The value of the optical densities for each isolate (ODi) was obtained by averaging the three wells, and this value was compared to the optical density of the negative control (ODc). The isolates were classified into four categories, according to the mean optical densities (ODi) in relation to the ODc results. If ODi ≤ ODc; considered non-adherent, ODc≤ODi≤2*ODc; considered moderately adherent and if 2*ODc≤ODi which considered strongly adherent[12].

Detection of Acyl-homoserine lactone(AHL) by colorimetric method: The isolates were incubated in 5 mL Mueller Hinton broth overnight at 37°C. 1.5 mL of the suspension was centrifuged at 10,000 rpm for 15 min, the supernatant was transferred and this step was repeated twice Subsequently liquid-liquid extraction using ethyl acetate for 10 min and the organic phase (top) was removed. Next, the samples were dried at 40°C, they transferred 40 µL to a microplate and added 50 µL of 1:1 solution of hydroxylamine 2 M: NaOH 3.5 M and 50 µL of1:1 solution of FeCl3 10% in HCl 4 M: Ethanol 95%. Finally, the optical density at 520 nm was measured in a plate reader.[13].

Rep-PCR profile and dendrogram construction (ERIC, RAPD, BOX)

E. coli DNA was prepared for PCR according to the method described [14].

Rep-PCR was performed using The ERIC forward primer (5'-ATGTAAGCTCCTGGGGATTCAC-3') and reverse primer (5'AAGTAAGTGACTGGGGTGAGCG-3')[15] were used to amplify repetitive equences present in the chromosomal DNA of E. coli isolates. ERIC-PCR was carried in 25µl, volume comprising of 100ng of E. coli DNA, 1.5µl (10 pmol) of each primer and 12.5µl Mastermixe. Filtered water was added to the mixture to make a final volume of 25µl. Reactions were carried out using a programmable thermocycler according to the following thermocycling conditions: initial denaturation at 94 °C for 1 minute, with the next 30 cycles consisting of a denaturation step at 94 °C for 30 seconds, annealing at 52 °C for 35 seconds, extension at 72 °C for 4 minutes, and a final extension for 5 minutes at 72 °C.

RABD(1247) (5 - AAGAGCCCGT-3) [16]. PCR was carried out in a 25µl reaction mixture, comprising of 100 ng of E. coli DNA, 1.5µl (10 pmol) each primer and 12.5µl Mastermixe. Filtered water was added to the mixture to make a final volume of 25µl. conditions were as follows 95°C for 15 min, 35 cycles of 94°C for 1 min, 38°C for 1 min and 72°C for 2 min, with a final 10 min elongation step at 72°C.

BOX (5 - CTACGGCAAGGCGAC-GCTGACG-3) (17). PCR was carried out in a 25µl reaction mixture, comprising of 100 ng of E. coli DNA, 1.5µl (10 pmol) each primer and 12.5µl Mastermixe. Filtered water was added to the mixture to make a final volume of 25µl.

Conditions were as follows: after an initial denaturation at 94_C for 5 min, 35 cycles of denaturation (94_C, 1 min), annealing (40_C, 2 min) and extension (72_C, 2 min) were performed, followed by a final extension (72_C, 10 min). Amplicons (15µl) were analyzed PCR products were detected in 1.5 % agarose gel, stained with ethidium bromide and visualized by transilluminator. Dendrograms were constructed using unweighted pair-group method of arithmetic average (UPGMA).

Results and Discussion

Ten *E. coli* isolates were obtained from 110 samples represented 9.09 % from the total samples collected from tap water the Baquba City between October tothe December 2019. *E. coli* identified known through the classical diagnostic and genetic diagnostic tests. All results shown in figure 1,2,3 and 4 also in Table 1.

All isolates of E. coli were tested for antibiotic sensitivity test according disck diffusion test against 12 different antibiotics Previously mentioned. The percentage of resistance to the antibiotics used as follows: Aztreonam was 80%, Cefpodoxime 70%, Trimethoprim- sulfamethoxazole 55 %, Cefoxitin 45%, Cefotaxime 45%, Doxycycline 70%, Azithromycin 60%, Ticarcillin-clavulanate 25%, Ampicillin-sulbactam 15%, Tetracycline 65%, Levofloxacin 50 % and Imipenem 30% as shown in the chart 1.

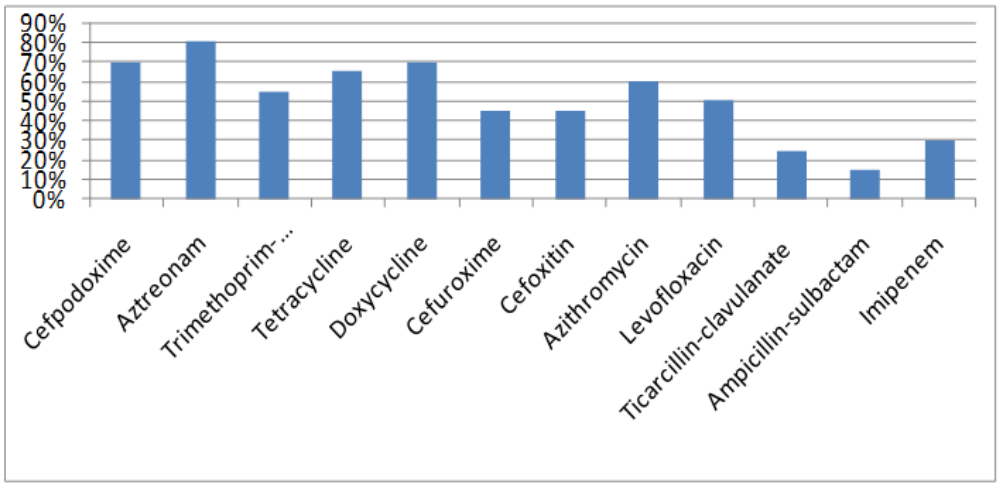

Fig. 1 : A diagram showing the resistance level of isolates for each Antibiotic

Transmission of the resistance between the intestinal family strains and the transition may be through spaying or bacterial coupling. Break the betalactam ring, or add proximity between the antibody and target sites (PBPs) or alter the permeability barrier [18,19].

Biofilm formation (Micro-titer plate method (MTP)): All *E coli* isolates from water were 10 (100%) isolates forming biofilms, 80% of isolates were Moderate biofilm where 20% of isolates were strongly biofilm

In other studies on bacterial resistance and biofilm formation in *E. coli* . in study for a total of 88 isolates the percentages of non-forming strains and weak, moderate and strong production capacity biofilms were 6.8, 36, 39.7 and 17.4%, respectively[20]

Detection of Acyl-homoserine lactone (AHL) by colorimetric method: Nine E coli isolates from water (90%) isolates Producer of Acyl-homoserine lactone.

Several studies have reported that *E. coli* is not able to produce AHL, yet has the ability to alter their pattern of gene expression and phenotypic properties in response to AHL[21].

Genotyping systems:

ERIC-PCR Profiling System: The isolates are classified according to the ERIC typing system and on the basis of the number of bands they own and according to the Dic program, the two main groups are apaered Group A and Group B:

The A group was characterized by having only 2 isolates . While group B was characterized by 8 isolates out of a total of 10 isolates under study. This group was divided into 2 subgroups under Group B, B1, B2 as shown in Diagram 2. The B1 group has one isolate only. The B2 group has 7 isolates.

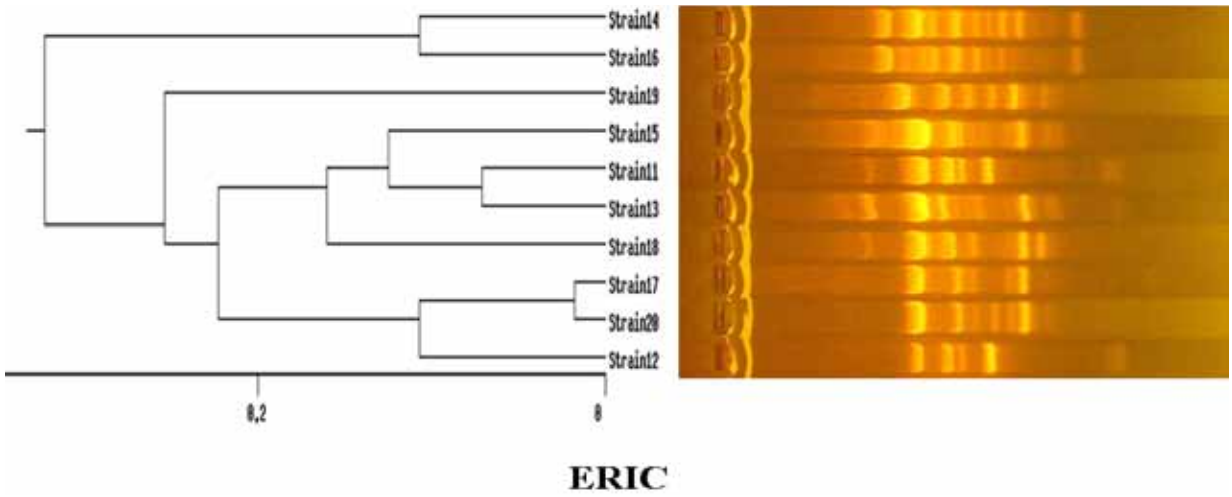

Fig. 2 :Dendritic analysis,and The resulting packets of ERIC - PCR reaction to some isolates of E.coli bacteria. (using electric relay technology for 1.5 hours and a voltage of 50 volts. The letter M denotes the volumetric guide 1kb

Many of the studies that used the ERIC-PCR system . Some of them differed in the size of the bands, their number or the number of patterns that emerged. Part of this difference may be due sometimes to the numerical variation of isolates used . The study explained that eighteen profoles each contained 2 to 5 isolates showing a similar genetic pattern. Similar genotype [22], The study showed that genetically modified isolates of the ERIC system of 27 different types can be grouped into 4 groups with similarities from 86 percent. Its bands are from 3 to 15 and the size is from 0.1 to 5.0 kb. [23]

BOX-PCR Profiling System: The isolates are classified according to the BOX typing system and on the basis of the number of bands they own and according to the Dic program, the two main groups are apaered Group A and Group B:

The A group was characterized by having 6 isolates. This group was divided into 2 subgroups under Group A, A1, A2 . The A1 group has two isolates. The B2 group has 4 isolates. While group B was characterized by 4 isolates. This group was divided into 2 subgroups under Group B, B1, B2 as shown in Diagram 3. The B1 group has one isolate only. The B2 group has 3 isolates.

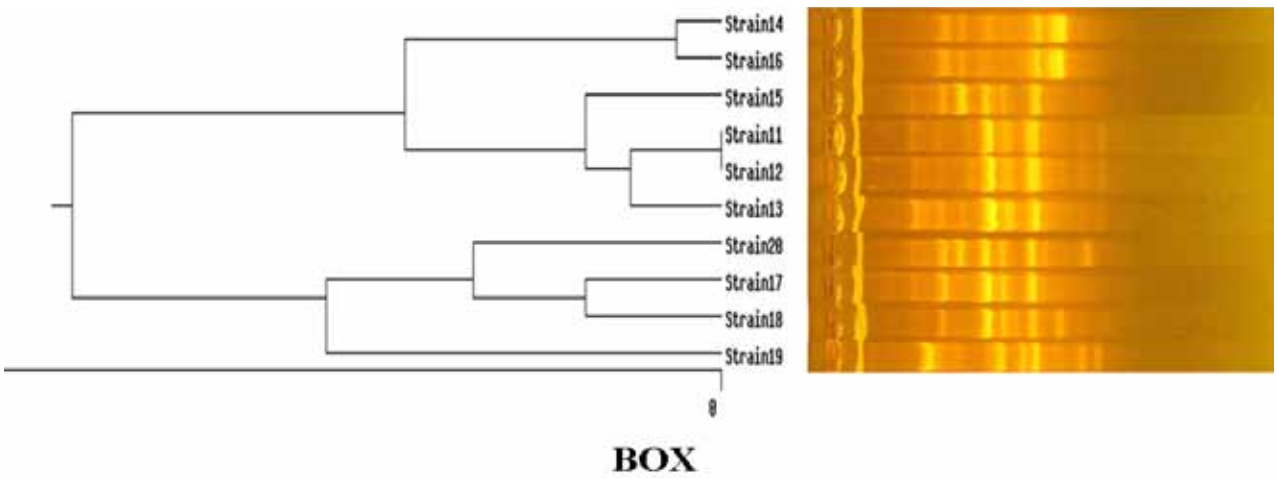

Fig. 3 :Dendritic analysis and the resulting packets of BOX- PCR reaction to some isolates of *E.coli* bacteria. (using electric relay technology for 1.5 hours and a voltage of 50 volts. The letter M denotes the volumetric guide 1kb)

BOX-PCR was second only to the PCR-5 GTG method. The researchers noted that the method of BOX-PCR showed high discriminative strength by generating 127 clear packets ranging from 0.16 to 3.9 kB whereas ERIC-PCR generated 61 packets ranging from 0.56 to[24]. The study also showed that stereotyping method that exploit the repeated elements distributed to the genome are more useful for assessing genetic diversity[25].

RAPD -PCR Profiling System: The isolates are classified according to the RAPD typing system and on the basis of the number of bands they own and according to the Dic program, the two main groups are apaered Group A and Group B:

The A group was characterized by having 6 isolates. This group was divided into 2 subgroups under Group A, A1, A2 . The A1 group has two isolates. The A2 group has 4 isolates. While group B was characterized by 3 isolates . This group was divided into 2 subgroups under Group B, B1, B2 as shown in Diagram 6. The B1 group has two isolated. The B2 group has one isolate. While one isolation was out group.

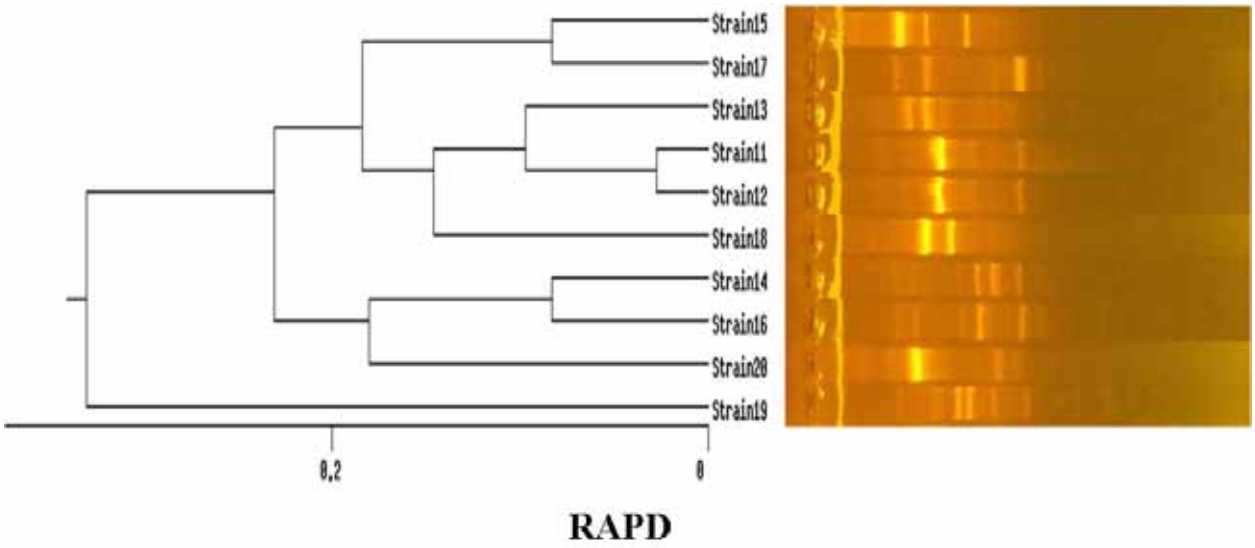

Fig. 4: Dendritic analysis and The resulting packets of RAPD- PCR reaction to some isolates of *E.coli* bacteria. (using electric relay technology for 1.5 hours and a voltage of 50 volts. The letter M denotes the volumetric guide 1kb)

The presented dual RAPD-PCR method has demonstrated a high level of resolution that allows for identification of distinct E. coli clones. Historically, RAPD assays have exhibited low reproducibility[26].

Table 1: Patterns of total isolates of *E. coli* according to the ERIC, BOX, RAPD system, number and percentage according to each category.

ERIC	**A**		**B1**	**B2**	
No. isolated	2		1	7	
Percentage %	20%		10%	70%	
BOX	A1	A2	B1	B2	
No. isolated	2	4	3	1	
Percentage %	20%	40%	30%	10%	
RAPD	A1	A2	B1	B2	Out group
No. isolated	2	4	2	1	1
Percentage %	20%	40%	20%	10%	10%
Total	10 (100%)				

Conclusion

The present study indicates that there is a correlation between taxonomic systems was evident by the distribution of isolates in each pattern and group.

Abstract

Hormones, their receptors, and the associated signaling pathways make compelling drug targets because of their wide-ranging biological significance to study the role of asprosin in obese male patients with diabetic mellitus type II. ELISA method was used to assay asprosin and insulin. Blood was taken with drawn sample from 30 obese normal patients with age range (40-60) years, 30 diabetic patients with age range (40-60) years at duration of disease (1-5) years and 30 normal healthy patients. The mean difference between T2DM according to insulin % (23.8±0.6) was increased than the mean of IFG (17.7±1.0) (P 0.000). The mean difference between T2DM according to asprosin (122.1±21.8) was increased than the mean of IFG (51.4±2.7) (P 0.000).the mean differences between DM2 and IFG cases in different weight groups (Ob., Ow. and Nw) according to insulin was studied, the results showed that, there were significant differences in DM and IFG obese groups (G1 and G2) according to insulin (24.18±1.13, 15.56±0.66) P (0.00), however, there were significant differences between DM and IFG in Normal weight groups (G5 and G6) according to insulin (19.98±0.93, 11.12) P (0.00), while no significant differences between DM and IFG in Over weight groups (G3 and G4) according to insulin (27.22±0.34,28.56±1.59) P (0.42).The mean differences between diabetic mellitus type 2 and impaired fasting glucose cases in different weight groups (obese, over weight and normal weight) according to Asprosin were shown in Table (3), Figure (). The results showed that, there were significant differences between DM and IFG in obese groups (G1 and G2) according to Asprosin (307.42±8.4, 66.3±2.2) P (0.00), However, there were significant differences between DM and IFG in overweight groups (G3 and G4) according to Asprosin (28.3±0.5, 51.7±3.2) P (0.00) In addition to that, there were significant differences between DM and IFG in normal weight groups (G5 and G6) according to Asprosin (30.5±1.7, 21.2±1.6)

Keywords: *Asprosin, obese patients, Diabetic Mellitus Type 2, IFG.*

Introduction

T2DM accounts for between 90% and 95% of diabetes, with highest proportions in low- and middle income countries(1). It is a common and serious global health problem that has evolved in association with rapid cultural, economic and social changes, ageing populations, increasing and unplanned urbanization, dietary changes such as increased consumption of highly processed foods and sugar sweetened beverages, obesity, reduced physical activity, unhealthy lifestyle and behavioural patterns, fetal malnutrition, and increasing fetal exposure to hyperglycemia during pregnancy. T2DM is most common in adults, but an increasing number of children and adolescents are also affected(2). The major causative of T2DM is due to the combination of disorder in insulin secretion via pancreatic β cells and peripheral insulin resistance (IR)(3). IR as a result of defects within signaling pathways of insulin in its target tissues(4). Insulin is a peptide hormone made up of 51 amino acids (a.a), it is created by the β-cells of the pancreas. Insulin peptide is primarily produced as preproinsulin and fractionate into proinsulin and later split into two peptides are C-peptide and insulin(5). Numerous factors are known to affect insulin formation. The unique and most significant physiological method that stimulates the process of transcription and translation atgene of insulin and RNA respectively is metabolism of glucose(6). In response to elevated glucose in the blood after ingestion and absorption from food, insulin is secreted in two phases and connects to insulin

receptors expressed in muscle, liver and adipose tissue. The secretion of insulin from β-cells of the pancreas is induced by elevation level of glucose mainly of fatty acid and amino acids in the blood. In both humans and rodents, after ingestion and absorption of food, glucose triggers a higher insulin response relative to other nutrients[8], the same amount of fat or combination of fat and protein results in just about a twofold elevation in plasma insulin level relative to the basal level[8].

Materials and Method

This study performed during period from September 2019 to December 2019 the subject were selected from Teaching Hospital/Medical City. Questionnaires were filled by participants and to get the agreement to participants in this study to collect the information of control and patients group.Blood samples were collected from control and patients group. The sample was drawn from the vein and stored by using (5mL) disposable syringe, all samples were collected in fasting status. The sample was keep into dispensable tubes containing a gel which facilitate the separation processes of serum and allowed to clot at 37˚C approximately at ten-fifteen min and then centrifuged at 2000 Xg for ten-fifteen min then the serum was stored at (-20˚C) until analysis (serum insulin andasprosin).

Subjects (patients and control groups): Subject were enrolled in this study to three group First group: patients 30 normal obese male with age range (40-60) years.Second group:DM type 2 (30) male with age range (40-60) years the duration of disease (1-5) years.Third group: 30 normal healthy male documented by physician or lab investigation matched in their age in both obese group.

Exclusion Criteria: Any Patient with the following problems was excluded from the current study.with renal dysfunction. Patient with heart diseases and hypertension. Patient with thyroid disorder. Insulin drug dependency. Any person with the chronic liver disease. Type 1 diabetic patient.

Inclusion Criteria: According to American diabetes association ADA criteria all patients are classified as DM type 2 by measurement blood glucose and HbA1c (ADA diabetes care 2019 Jan, 42:s13-s28). Also regard to WHO criteria all patients are classified according BMI.

Measurement of Human asprosin[9]: Standard wells, a volume of 50µl of the standard solutions were added to the standard wells. Then a volume of 10µl of the sample was added followed by 40µl of sample diluent was added to the testing sample well, in blank nothing to add. After that, a volume of 100µl of HRP-conjugate reagent was added to each well and then covered by used adhesive strip followed by incubation for sixty min at 37°C.The cover on a plate was removed and starting to wash process, the wash process was repeated for four times using 400µl of Wash Solution each time by an auto washer. A volume of 50µl of chromogen solution (A) and (B) was added to each well and mixed gently and followed by incubation period at 37°C for 15 min. This addition should be protected from light. Next a volume of 50µl Stop Solution was added to each well. The color in the wells converts from blue color to yellow color. If the color in the wells become green or the color change does not appear uniform, the plate should gently coverd to ensure good mixing. Afterwards a microtiter plate reader was used to read the absorption within 15 min at 450 nm.

Measurement of insulin[10]: Standard wells, a volume of 50µl of the standard solutions were added to the standard wells. Then a volume of 10µl of the sample was added followed by 40µl of sample diluent was added to the testing sample well, in blank nothing to add. After a volume of 100µl of HRP-conjugate reagent was added to each well and then covered by used adhesive strip followed by incubation for sixty min at 37°C. The cover on a plate was removed and starting to wash process, the wash process was repeated for four times using 400µl of Wash Solution each time by an auto washer. After that, a volume of 50µl of chromogen solution (A) and (B) was added to each well and mixed gently and followed by incubation period at 37°C for 15 min. This addition should be protected from light. Then a volume of 50µl Stop Solution was added to each well. The color in the wells converts from blue color to yellow color. If the color in the wells become green or the color change does not appear uniform, the plate should gently coverd to ensure good mixing. A microtiter plate reader was used to read the absorption within 15 min at 450 nm.

Statistical Analysis: The version twenty of SPSS was used to complete Statistical analysis. (Means ± SD) were used to represent the variables. The comparison between patients group and control group was done by use student t-test; with a *p*-value of ≤ 0.001 was considered a significant. The method that used to find the relationship between two continuous variables was correlation coefficient (r).

Ethical Approval: Agreement from patients for sampling collection and carrying out this work is obtained from each patient.

Results

In Figure (1), the mean difference between T2DM according to insulin % (23.8±0.6)was increased than the mean of IFG (17.7±1.0) (P 0.000). The mean difference between T2DM according to asprosin (122.1±21.8) was increased than the mean of IFG (51.4±2.7) **(**P 0.000).

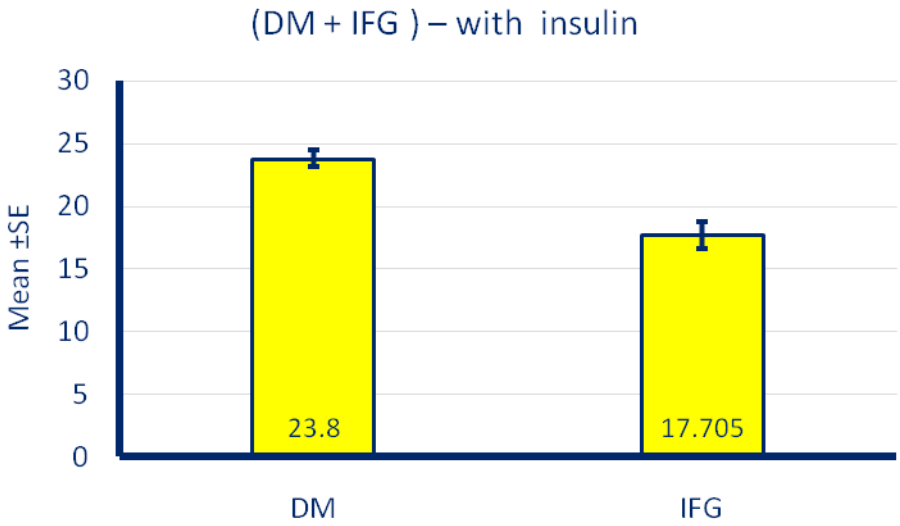

Figure (1) Mean difference between diabetic mellitus type 2 (DM2) and impaired fasting glucose (IFG) patients according to insulin P (0.000).

In Figures (2), the mean differences between DM2 and IFG cases in different weight groups (Ob., Ow. and Nw) according to insulin was studied, the results showed that, there were significant differences in DM and IFG obese groups (G1 and G2) according to insulin (24.18±1.13,15.56±0.66) P (**0.00**), however, there were significant differences between DM and IFG in Normal weight groups (G5 and G6) according to insulin (19.98±0.93,11.12) P (**0.00**), while no significant differences between DM and IFG in Over weight groups (G3 and G4) according to insulin (27.22±0.34,28.56±1.59) P (0.42).

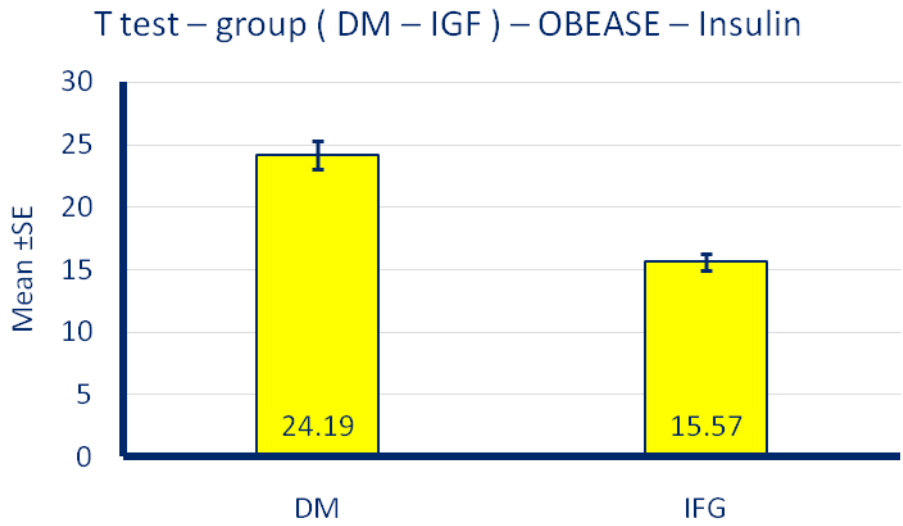

Figure (2): Mean differences between DM 2 and IFG cases in Ob. Cases in different weight groups according to insulin P (0.00)

The mean differences between diabetic mellitus type 2 and impaired fasting glucose cases in different weight groups (obese, over weight and normal weight) according to Asprosin were shown in Table (3). The results showed that, there were significant differences between DM and IFG in obese groups (G1 and G2) according to Asprosin (307.42±8.4, 66.3±2.2) P (0.00),However, there were significant differences between DM and IFG in overweight groups (G3 and G4) according to Asprosin (28.3±0.5, 51.7±3.2) P (0.00) In addition to that, there were significant differences between DM and IFG in normal weight groups (G5 and G6) according to Asprosin (30.5±1.7, 21.2±1.6).

Table (3): The mean difference between DM2 & IFG cases in different weight groups (Obese, Overweight, Normal weight according to Asprosin

Groups	Sub groups	Asprosin ng/L	P-value
Obese	DM/G1	307.42±8.4	0.00
	IFG/G2	66.3±2.2	
Over weight	DM/G3	28.3±0.5	0.00
	IFG/G4	51.7±3.2	
Normal weight	DM/G5	30.5±1.7	0.001
	IFG/G6	21.2±1.6	

Discussions

These results were agreement with results obtained by[11] who found that,there were significant differences between IFG and Insulin and ($P < 0.005$). Another study of[12] found that, there were significant differences between T2DM and insulin $P< 0.001$**.** Asprosin functions to increase plasma glucose levels, and circulating asprosin levels are increased by fasting (a baseline glucose condition) and decreased by feeding a high glucose condition[13]. Asprosin might be a risk factor associated with the development of T2DM. Adipose tissue has the endocrine role to regulate metabolism and balance energy homeostasis[14]. Several adipose tissue-secreted molecules can either enhance or impair insulin action [15]. Insulin resistance, a major cause of T2DM, is one of the most remarkable changes which occur with excess adiposity. Thus, obesity is causally inked to a constellation of metabolic diseases such as T2DM and metabolic syndrome[16]. Humans with insulin show pathologically elevated plasma asprosin, and its loss of function through immunological or genetic means has a profound glucose and insulin lowering effect secondary to reduced hepatic glucose release[17]. Therefore, therapeutically targeting asprosin might be beneficial in type 2 diabetes mellitus patients[18]. Hepatic glucose release into the circulation is vital for brain function and survival during periods of fasting and is modulated by an array of hormones that precisely regulate plasma glucose levels. A fasting-induced protein hormone that modulates hepatic glucose release. It is the C-terminal cleavage product of profibrillin, and we name it Asprosin[19]. Asprosin is secreted by white adipose, circulates at nanomolar levels, and is recruited to the liver, where it activates the G protein-cAMP-PKA pathway, resulting in rapid glucose release into the circulation[20].

Conclusion

There were significant differences between DM2 patients according to asprosin and insulin, and there were significant differences between IFG cases according to asprosin and insulin.

The Effect of the Advanced Organizations 'Strategy on Attentional Control and Learning Some Offensive Skills Installed with Basketball for Students

Ahmedkhalid Awad

Lect., Al Maarif University College, Department of Physical Education and Sports Sciences, Iraq

Abstract

The researcher used the experimental method with the two experimental and control groups with the two pre and post tests on his sample of 65 students from the second stage students in the University College of Knowledge, Department of Physical Education and Sports Sciences. Researcher measure attentional control on a sample The main experiment, in addition to conducting skill tests, after which the curriculum for the strategy of advanced organizations was applied, and then the researcher used appropriate statistical means to extract the results, and in the light of the results he reached a number of conclusions, which are that the attentional control helped the students in the smart diversity in thinking method and solving the problems they face, the effect The units prepared by the researcher over the experimental group, as they outperformed the control group in developing the offensive skills combined with basketball because they were suitable for the sample and varied with its exercises, tools and method used, and in light of the conclusions the researcher recommends the following: Examine the students and know the level of attention control they have at the beginning of each An educational season, the adoption of educational units prepared according to the strategy of advanced organizations in learning complex offensive skills with basketball, the need to pay attention to modern teaching strategies that carry with them method based on behavioral and constructivist theories and meaningful learning that contribute to raising the level of students and developing the educational process.

Keywords: *Strategy, attention and skills; rehabilitations; students activity; teaching modern.*

Introduction

Students in general, and university students in particular, are the basic building block for community building as they are the source of conscious young energies capable of building society in a way that makes it a developed society. Therefore, caring for the level of this segment and preparing it well must be a priority and this is done through the use of thoughtful strategies and plans that raise the mental and scientific level Strategies are considered one of the most important types of educational plans based on the foundations of psychological theory that give the learner experiences and effective mental capabilities that will activate the role of the learner within the educational community. Strategies often focus on the mental aspect, method of thinking, and the emotional state of students, and strategies transfer practices and theoretical sciences. To be applied, as is the case in the sports field, where these strategies play an important role in learning skills and raising them to higher levels by providing him with information and directing him towards correct learning method as well as enhancing the learner's self and his internal ability to reach the state of learning and then creativity in the learned skill.[1]

The strategy of advanced organizations is one of the strategies that can be used to facilitate learning, and it consists of an introduction and an introductory material that is presented to the learner prior to learning the new material and is general and comprehensive, aiming to provide the learner with a general knowledge base on

e-mail: a.k.awad@uoa.edu.iq

which to build in the formation of concepts, principles and main ideas. Attention control is important in the learning process by enabling the individual to regulate his behavior and control it. The student who is able to observe himself is the one who has positive internal directives towards the educational process and thus is able to plan for his learning and organize himself as he is the most capable of solving problems and facing the challenges that It is imposed by difficult tasks, and self-monitoring can give the learner an opportunity to develop his learning styles and give him better competencies for performance by demonstrating greater levels of ability and motivation.[2]

The basketball game is one of the competitive team games that took the lead in terms of its spread in the world and which contains in its content a number of complex offensive skills, as the complex offensive skills are important and difficult skills that the player cannot easily perform, as they need a longer time And a greater effort to learn and master it, as learning and mastering it is an effective element in achieving the best results in matches.Hence the importance of research in using this strategy in developing attentional control and learning the offensive skills combined with basketball because of the important educational steps it contains in addition to the use of various educational method that help to transmit information more clearly and this is what called the researcher to conduct experimental research in order to contribute to Developing the educational process and enriching it by creating effective means that stimulate the minds of students, thus helping to facilitate information acquisition, storage and retrieval faster.[3]

Research Objectives:

1. Identifying the degree of attention control among second-stage students in the University College of Knowledge/Department of Physical Education and Sports Sciences.
2. Preparing educational units using the strategy of advanced organizations to learn some offensive skills combined with basketball for the research sample.
3. Identify the impact of the advanced organizations 'strategy on attention control and learn some offensive skills combined with basketball for the research sample.

Research Fields:

- **The human field:** A sample of the second year students in the University College of Knowledge/ Department of Physical Education and Sports Sciences.
- Time range: The period from 2-11-2019 to 1-13-2020.
- Spatial field: the interior hall and classrooms of the University College of Knowledge.

Research Methodology

Research community and sample: The research community was determined by the intentional method, and they are the second stage students in the University College of Knowledge/Department of Physical Education and Sports Sciences for the academic year (2019-2020) and their number is (95) students distributed among (3) people. Division (A) is the experimental group of (33) students, and Division (B) is the control group, whose number is (32) students, so that the total number is (65) students.

Table 1. Shows the division of the research sample

Classes	Groups	Number of student
A	Experimental	33
B	Control	32
C	Pilot	5
Total	**-**	**70**

Means, devices and tools used in the research

- Arab sources.
- Attention Control Scale.
- Tests used.
- Educational units.
- Statistical means.
- Polling questionnaires.
- Forms to record and dump data.
- Observation and experimentation.
- A questionnaire for the attentional control scale.
- Dell computer (1).
- Sony (1) photography camera.
- A tape measure to measure distances.
- Manual stopwatch, count (1).
- Legal basketball Molten 6G, count (33).

Field research procedures

Determination of complex offensive skills in basketball: Skills are learned from the first stage. Therefore, within the second phase curriculum of the first semester is learning to link between previously learned offensive skills, and among these skills is handling, patience and scoring.[4]

Determine the skill tests: Often the researcher needs to choose or develop multiple tests to measure some of the variables that are related to the phenomenon to be measured, so the researcher must choose some tests that measure what you really want to measure, so the researcher, being a teaching basketball specialist, chose the compound offensive tests.[5]

The following describes the tests used in the research:

The first test: receiving and a high chuck ending in peaceful correction[6]

- The purpose of the test: To measure the ability to receive and dribble (dribble) high, ending in peaceful scoring.
- Necessary tools: A basketball court, four hurdles, a person, eight (8) legal basketballs, a leather tape measure (20 meters), a tape, an electronic stopwatch, two chairs, and a whistle.

The second test: Receipt ending with a jump shot[7]

- **The purpose of the test:** To measure the ability to receive ending with a jumping shot - two points.
- **Necessary tools:** A basketball court, three barriers, 10 legal basketballs, a leather tape measure (20 meters), adhesive tape, an electronic stopwatch, two chairs, and a whistle.

Determine the scale used:

Attention Control Scale: The researcher has reviewed many sources, scientific references, studies and research for the purpose of finding a scale through which to identify the amount of attention control for a sample of research, and the researcher did not find anything other than the scale prepared by,[8] which consists of (37) paragraphs Distributed in three dimensions (attention focus - attention shift - control flexibility of attention) I have placed five alternatives in front of each paragraph and the answer is one of the alternatives and it applies to me always, applies to me, applies to sometimes, applies to me rarely, does not apply to me at all.[9]

The Attention Control Scale Correction Method: To calculate the degree that the respondent gets through his answer to the scale paragraphs, the researcher identified five alternatives and five weights, which are (they apply to me always, they apply to me often, they apply to me sometimes, they apply to me rarely, they do not apply to me) by comparing the laboratory answer with the correct answers prepared in advance Its grades were determined gradually for positive (1,2,3,4,5) and negative (5,4,3,2,1) paragraphs, and accordingly, the lowest score for the scale obtained by the laboratory is (37) and the highest score (185) with an hypothetical average (111).

Pre-tests: The researcher carried out the pre-tests on the research sample (control group and experimental group) during two consecutive days. On Tuesday, November 5, 2019 AD, the Attention Control Scale was applied in one of the classrooms in the University College of Knowledge, Department of Physical Education and Sports Sciences. Students answer the scale paragraphs honestly and objectively, because of its great importance for scientific research and the educational process.

Table 2. Shows the parity of the two research groups in the pre-skill tests and the Attention Control Scale

Tests	Experimental group			Control group			(t) value	Statistical significance
	N	Mean	SD	N	Mean	SD		
Attention Control Scale	33	119.520	2.849	32	111.540	4.895	1.612	No sig.
Receipt and high chuck ending in peaceful correction	33	2.23	0.461	32	1.90	0.323	0.087	No sig.
Receipt ending by shooting from a jump	33	2.27	0.116	32	1.82	0.114	0.313	No sig.

Results and Discussions

Table 3. Shows the mean, standard deviations, and the value of (t) calculated between the pre-test and the post-test of the experimental group in the investigated variables

Variables	Pretest		Posttest		Mean diff.	SD diff.	(t) value	Statistical significance
	Mean	SD	Mean	SD				
Attentional control	119.520	2.849	162.436	3.364	42.796	8.563	25.966	Sig.
Receipt and high chuck ending in peaceful correction	2.23	0.461	3.01	0.138	0.76	0.126	31.556	Sig.
Receipt ending by shooting from a jump	2.27	0.116	3.25	0,110	0,97	0.115	43.945	Sig.

Table 4. Shows the mean, standard deviations, and the value of (t) calculated between the pre-test and the post-test of the control group in the searched variables

Variables	Pretest		Posttest		Mean diff.	SD diff.	(t) value	Statistical significance
	Mean	SD	Mean	SD				
Attentional control	111.540	4.895	150.40	16.47	41.434	17.336	12.420	Sig.
Receipt and high chuck ending in peaceful correction	1.90	0.323	2.26	0.141	0.34	0.135	13.127	Sig.
Receipt ending by shooting from a jump	1.82	0.114	2.30	0.123	0.44	0.110	21.027	Sig.

Table 5. Shows the mean, standard deviations, and the value of (t) calculated between the experimental and control groups in the post tests of the investigated variables

Variables	Experimental group		Control group		(t) value	Statistical significance
	Mean	SD	Mean	SD		
Attentional control	162.436	3.364	150.400	16.470	8.232	Sig.
Receipt and high chuck ending in peaceful correction	3.01	0.138	2.26	0.141	4.262	Sig.
Receipt ending by shooting from a jump	3.25	0.110	2.30	0.123	3.640	Sig.

Through the results that were presented and analyzed in the tables above for the pre and posttests of the experimental group, we find that there is a remarkable development in the level of skills learning, and the researcher attributes the moral differences between the pre and posttests of the experimental group to the effectiveness of the strategy of the advanced organizations because it encouraged students to organize their ideas according to their method appropriate to their abilities. Mentality by placing students in new educational situations in which they can develop the information they possess and stimulate their mental abilities, which leads to the survival of the information for a longer period.[10]

The researcher attributes the moral differences between the pre and posttests of the Attention Control Scale to the effectiveness of the strategy used. The acquisition of attention control by group members is evident by that it enables the individual to regulate and control his behavior and that the student who is able to observe himself is the one who has positive internal directives towards the educational process. An ability to solve problems and face the challenges posed by educational situations, as self-monitoring can give students an opportunity to develop learning method and acquire better competencies for performance by showing greater levels of ability and motivation.[11]

To consider the research sample are students of the second stage, as they have previous experience with basketball skills, and this provides them with the ability to enter new information and link it to the information obtained in the educational position with the information

he has in his cognitive structure and this is clearly reflected in improving his level of achievement and increasing his motivation for learning And the impact of learning remains and all this leads to directing the mind with flexibility and attention between and within tasks to achieve the maximum extent of performance.[12]

As for the control group, the researcher attributes the simple development of it to the fact that the method used in learning are traditional with little diversification and rarely have excitement or suspense, [13](The lack of use of learning strategies and the lack of diversification in method in addition to the absence of some kind of excitement. And the excitement in physical education lessons leads to the lack of development of the level of the control group significantly,[14] In addition, the role of the student or the learner is limited to the role of the recipient, since the method used in teaching the control group is a method that depends on the teacher in a very large percentage, while the role of the student is secondary (as the traditional method is an imperative style on the part of the teacher and makes the student bound by the instructor's instructions and does not give him the freedom to perform, since the student's role here is to receive information and directions, which affects the level of his education) .[15]

Conclusions

1. Attention control helped students to have a smart diversity in thinking styles and problem solving.
2. Karen's model and the method used by the teacher contributed to the development of mental fitness, attentional control, and attacking skills combined with basketball among the research sample, but to varying degrees.
3. The effect of the units prepared by the researcher on the experimental group, as they outperformed the control group in developing the offensive skills combined with basketball because they were suitable for the sample and varied with its exercises, tools and method used.

The Effect of Rehabilitative Physical Exercises to Develop Some Aspects of Muscle Strength and Range of Motion in Rehabilitating the Deltoid Muscle of the Shoulder Joint of Badminton Players

Mustafa Muhammad Ali Farhan[1], Salman Dawood Tuaimah[2]

[1]Lect., Wasit University, College of Physical Education and Sports Sciences, Iraq,
[2]Asst. Lect., Wasit Governorate, MOE, Iraq

Abstract

The importance of the research came in preparing rehabilitative exercises for the deltoid muscle in the shoulder joint using exercises with different resistances and angles. The researchers believe that the problem is that the rehabilitation programs that suffer from a lack of reliance on various exercises, devices and weights, as well as angles to determine the degree of pain, which is one of the most important factors in the speed of the process Rehabilitation and symmetry of recovery Therefore, the researcher decided to prepare rehabilitative exercises for the deltoid muscle injury using some different resistance, weights and angles, and try to benefit from them to rehabilitate these injuries to return the injured to practicing sports activity in the shortest possible period. The research aims to:

1. Preparing rehabilitative exercises for the deltoid muscle injury using some different resistances, weights and angles for the subjects of the research sample.

2. Identifying the effect of rehabilitative exercises for the deltoid muscle injury by using some different resistances, weights and angles among the members of the research sample.

The experimental method was used with one group and the number of injured (4) badminton was advanced in Wasit governorate for the 2018-2019 season, and the researchers concluded that the proposed rehabilitative exercises have a positive effect by restoring the normal range of motion on the muscle groups working on a joint, and it is recommended that the means should be used. Therapeutic and auxiliary means to rehabilitate muscle injury in carrying out rehabilitative exercises in line with the level of injury.

Keywords: *Rehabilitative physical exercise, deltoid muscle, shoulder joint and badminton.*

Introduction

The ability of this joint to move is very large as it moves in all directions, but it lacks some strength and consists of the humerus joint with the muscular fossa of the scapula. The shoulder blade injury is one of the common injuries in badminton, where many occur either as a result of a strong movement such as sending or when pressing over the head, especially when the player neglects the appropriate warm-up procedure to prepare the joint muscles well, which leads to the rupture of the joint fibers and the occurrence of internal bleeding that results in the passage of time Calcium calcification, which requires removal by surgery, so attention must be paid to warm-up exercises, especially strength and flexibility exercises, in addition to performing some real movements of sending or pressing during the warm-up

Lect., Wasit University, College of Physical Education and Sports Sciences, Iraq
e-mail: mustafa_teacher81@yahoo.com

period without a ball first and then using the ball in order to increase the readiness of the joint muscles and prepare them for the performance of physical effort, and the importance of the research came In using rehabilitative exercises to injure the deltoid muscle in badminton players for the purpose of subjecting them to this type of rehabilitation and in order to achieve complete recovery.[1]

The researcher believes that the problem is that the rehabilitation programs that suffer from a lack of reliance on various exercises, devices and weights, as well as angles to determine the degree of pain, which are considered one of the most important factors in the speed of the rehabilitation process and the symmetry of recovery. And try to benefit from them to rehabilitate these injuries, to return the injured to practicing sports activity in the shortest possible period.[2]

Research Objectives:

1. Preparation of a proposed rehabilitation approach to rehabilitate the deltoid muscle injury in badminton players.
2. To recognize the effectiveness of rehabilitative exercises in rehabilitating the deltoid muscle injury of badminton players.

Hypothesis:

- Rehabilitation exercises have a positive effect in rehabilitating the partial rupture of the deltoid muscle in badminton players.

Fields of Research:

- The human field: a sample of advanced badminton players in Wasit governorate clubs.
- Timing range: 5/1/2019 to 15/7/2019.
- Spatial domain: badminton playgrounds in Wasit Governorate.

Research Methodology: The researcher used the experimental method for its relevance to the nature of the research.

The research community and its sample: The researcher selected the research sample in an intentional way to include a number of players injured in the semantic muscle of the shoulder joint, and their number reached (4) injured players playing badminton for Wasit Governorate for the 2018 season and they were homogeneous in the research variables as in Table (1).

Table 1. Shows the homogeneity between individuals of the research sample in the morphological measurements and the study variables

Variables	Measuring unit	Mean	Standard deviation	Mediator	Coefficient of torsion
Length	cm	181.75	5.377	182.50	-0.574
Weight	kg	65.25	1.708	65.50	-0.753
Biological age	Year	21.50	5.802	21	0.491
Tide forward shoulder	Degree	17	1.826	17	0.000
Shoulder movement	Degree	35	3.559	34	0.842
Explosive force	Mater	4.754	0.45	4.902	-0.986
Fast power	Number	6.416	0.523	6.250	0.952

The results of Table (1) show that the values of the torsion coefficients for the variables contained in it were specified between (± 1), and that they are within the (kaus) curve of the normal distribution, which means the homogeneity of the search sample.

Method of gathering information

- Arab and foreign references and sources.
- Standardized tests for some physical characteristics and the normal range of motion of the shoulder joint.
- Stopwatch .
- Height and weight measuring device.
- The geometer.
- Tape measure.

- Medicine balls of (3-5) Kg.
- Various sports iron weights and equipment.

Tests of the normal range of motion of the shoulder joint[3]

The dynamic range of the shoulder joint was measured.

Shoulder Extension Forward:

- The laboratory sits facing the device, with its arm at an angle (90) between the upper arm and the forearm.
- The arm is placed on the device and on the far side of the arm.
- The lab pushes its arm forward.
- The arm fixed on the device is parallel to the torso.
- The moving arm on the device is parallel to the hummers.
- Read and record the degree achieved from the extent of the arm's reach to the highest point of the degree of pain and the measurement with the tape attached to the device.
- The ideal range of motion for shoulder flexion motion is (0-60) degrees.

Extended Shoulder Movement:

- The laboratory sits facing the device, with its arm at an angle (90) between the upper arm and the forearm.
- The arm is placed on the device and on the far side of the arm.
- The laboratory is removing his arm out of the body.
- The arm fixed on the device is parallel to the torso.
- The moving arm on the device is parallel to the hummers.
- Read and record the degree achieved from the extent of the arm's reach to the highest point of the degree of pain and the measurement with the tape attached to the device.
- The ideal range of motion for off-shoulder extension motion is (0-60) degrees.

Muscle strength tests

Test of throwing a 3 kg medicine ball with two hands from a sitting position on a chair[4]

- The purpose of the test: to measure the explosive power of the muscles of the arms and shoulder.
- The tools used: a medicine ball weighing (3) kg, a measuring tape, and a chair with a strap for fixing the trunk.
- Description of the test method: The laboratory sits on the chair and the medical ball is carried by hands over the head and the torso is adjacent to the edge of the chair, the belt is placed around the trunk of the laboratory and held from the back in a controlled manner for the purpose of preventing the laboratory from moving forward during the throwing of the ball with the hands, so that the process of throwing the ball with two hands without using the trunk Each laboratory is given three attempts to score the best.
- Scoring: The distance between the front edge of the chair and the closest point the ball makes on the floor is calculated.

From the front support position, bend the arms and extend them in (10) seconds[5]

- The purpose of the test: to measure the velocity characteristic of the muscles in the arms.
- Tools used: a verifier to evaluate and calculate the correct attempt, stopwatch.
- Performance description: From the front stand position, the tester bends the elbows until it touches the ground with the chest, then returns again to the stand. The performance is repeated as many times as possible within (10) seconds according to the specified conditions.
- It is not allowed to stop during the test.
- The body must be straight during the performance.
- The necessity to bend the elbows completely and extend them to their maximum extent
- Any violation of the conditions, the attempt will be canceled
- Recording: Counts the number of times the correct performance is repeated within (10) seconds.

Pilot Study: In order to identify the positive and negative aspects that may appear in the future and for the purpose of avoiding them and developing, deleting or modifying some research steps and to ensure the suitability of the proposed period of time for the rehabilitative unit and for the purpose of ensuring the safety of the work of devices and tools and identifying the validity of the measurements and tests used in the research and the ability of the researcher and the work team On its performance and implementation, the researcher conducted a preliminary exploratory experiment on a sample of (2) individuals from infected patients on Saturday (4/5/2019). When conducting the pilot experiment, the same conditions and conditions as the main experiment must be met as much as possible so that Taking its results .[6]

An exploratory experiment was conducted as follows:

1. An exploratory experience to see the success of the tests in the curriculum, validity, equipment and tools, their safety, and the assistant staff.
2. Knowing the difficulties and obstacles that the researcher may face while applying the exercises.
3. Making some adjustments to the vocabulary of the rehabilitation curriculum in terms of repetition and sequence of rehabilitative exercises placed therein.
4. Conducting a rehabilitation unit to know the time and recurrence.

Pre-tests: The researcher conducted the pre-tests procedures (before the rehabilitative curriculum) after taking the magnetic resonance rays and then determining the severity of the injury by reading the resonance by a specialist doctor. The pre-tests were done on Thursday 9/5/2019 at exactly five o'clock in the afternoon in Wasit Stadium on the search group after That the test is shown to the research sample in order to obtain all the variables through performance.

The proposed rehabilitation curriculum (the main experiment): The researcher prepared the rehabilitative exercises using the proposed device and using multiple means and added weights (weights) for a period of two months and at three rehabilitative units per week, then he presented them to the experts to see the suitability of the exercises that he applied to the injured:

- The prepared rehabilitation curriculum includes performing exercises to rehabilitate shoulder joint injuries. The purpose of these exercises is to rehabilitate the deltoid muscle of the shoulder joint as well as increase the range of motion and try to return the range of motion to the normal range and in all directions of movement.
- The researcher took into account the principle of a gradual increase in the resistance position, from easy to difficult, by using passive exercises at the beginning of the curriculum (the first week), then gradually increasing the difficulty of exercises in the following weeks, using self-resistance exercises (weight and body parts) with the development of external resistances.
- The rehabilitative unit included physical exercises and the exercises were using body weight and weights, and the focus was on the use of resistance and then exercises using medical balls in order to give the body an opportunity and sufficient time to recover from the injury before the injured muscle returns to its normal state before the injury as much as possible and to engage in any physical activity that requires effort. Physical level of intensity, in addition to performing various movements in different directions that would give the injured shoulder joint the ability to restore the normal range of motion that was determined by the injury, especially when the members of the sample are among the players who suffer from a specific injury, as for physical exercises The researcher was keen on preparing a method that would rehabilitate the working muscles on the shoulder joint in general and the deltoid muscle in particular, and it depends on the strength and flexibility of the muscles working on it. The exercises to increase the range of motion and rehabilitate the working muscle that are very necessary in sports such as tennis, badminton, handball and swimming,[7] the researcher took care of the diversification and change in the rehabilitative exercises used in terms of the type of exercises and their basic conditions.

The content of the rehabilitative exercise was:

1. The exercises included work on pain control, rehabilitation of injured tissues, and focus on correcting joint function and returning to normal position.
2. The difficulty of rehabilitative exercises was adopted from (50%) to the arrival of the injured similar to severe recovery (80%) for strength and range of

motion exercises, and the number of repetitions and groups depending on the source .[8]

3. The time period for implementing the rehabilitative exercises amounted to (8) consecutive weeks.
4. The number of rehabilitative units per week reached (3) sessions on (Saturday, Monday, and Wednesday) days of the week.
5. The total number of college rehabilitative units (sessions) is (24) rehabilitative units.
6. The rehabilitation unit time (30) minutes.

Post test: After the end of the qualifying curriculum, the post-test was conducted on the research sample on Thursday 4/7/2019 at 5 p.m., taking into account the same pre-test conditions on a laboratory, as the researcher was keen to create the same conditions for testing in terms of time and place and the assistant work team Same (in the pre and post tests), tools and devices in order to fix the variables as much as possible.

Statistical method:

The researchers used the social statistical bag (SPSS) to calculate each of the values of:

- Mean .
- Mediator .
- Standard deviation .
- Coefficient of torsion.
- t-test for cross-linked samples.

Results and Discussions

Presentation and analysis of the results of the pre and post test for the range of motion and physical tests of the deltoid muscle of the shoulder joint for the research group

Table 2. Shows the means, standard deviations, and the calculated value (t) and the significance of the kinematic and physical range test for the pre and post tests.

Variables	Measuring unit	Pretest		Posttest		p	Pe	(t) Calculated	Moral value	Indication
		Mean	St.d	Mean	St.d					
Tide forward shoulder	Cm	17	1.826	22.75	1.708	5.75	1.258	9.139	0.003	Moral
Shoulder movement	Cm	35	3.559	39.75	3.304	4.75	1.708	5.563	0.011	Moral
Explosive force	Mater	4.613	0.395	5.261	0.263	0.64	1.649	3.724	0.014	Moral
Fast power	Number	6.416	0.523	7.816	0.447	1.4	1.716	3.355	0.035	Moral

Significance when (Sig)> (0.05), degree of freedom (n - 1) = 4 - 1 = 3, significance level (0.05)

Table (2) shows us the values of the mean and the standard deviation and the extent of their difference before and after the implementation of the rehabilitative curriculum for the tests of the normal range of motion and the muscle strength of the deltoid muscle of the shoulder joint, which indicates that the differences are in the post test, meaning that there is an effect of the experimental variable, and to know the truth of this Change and its statistical significance The researcher used the (t) test for the correlated samples, as we find that the mean of the tide variable forward in the pre-test reached (17) with a standard deviation (1.826), while the mean in the post test reached (22.75) and with a standard deviation (1.708). The calculated value of (t) reached (9.139), which is greater than its tabular value of (3.182) under the level of significance (0.05) and at the degree of freedom (3), which indicates the existence of a significant difference between the pre and post tests and in favor of the post test.

Table (2) shows us that the mean of the outward tide variable in the pre-test reached (35) with a standard deviation (3.559), while the mean in the post test reached (39.75) and with a standard deviation (3.304), and the calculated value of (t) reached (5.563) and it is greater than its tabular value of (3.182) below the level of significance (0.05) and at the degree of freedom (3), which indicates the existence of a significant difference between the pre and post tests and in favor of the post test.

While we find that the mean of the variable (explosive power) in the pretest was a value of (613.4) and a standard deviation of (395.0), while we find that the mean in the post test of the variable itself was a value (261.5) and a standard deviation of (263.0), and when calculating the value of (t), we find it with a value of (724.3) and since the statistical significance is (014.0) and it is less than the level of significance (05,0), this indicates the presence of significant differences between the pre and post tests and in favor of the test Post. Whereas we find that the mean of the variable (force characterized by velocity) in the pre-test was the value (416.6) and a standard deviation of (523,0), while we find that the mean in the post test of the variable itself was the value (816,7) and a standard deviation Its value is (047,0) and when calculating the value of (t), we find it with a value of (355,3), and since the statistical significance is (013,0) and it is less than the level of significance (05,0), this indicates the presence of significant differences between the pre and post tests For the benefit of the post test.

By looking at the results of Table (2), the two researchers note that there are differences in the mean between the two pre and post tests in the variables of the kinematic range (extension backward, forward bending, transmission) for the research group and in favor of the post test compared to the pre-test, [9]"That the increased range of motion means an improvement in the elasticity of the muscles and ligaments surrounding the joint as well as an improvement in the work of the neuromuscular in controlling the work of the sensors responsible for providing the sensory information to the brain about this range."[10] From here as if the proposed device and the application of applied exercises prepared have a positive effect in improving The kinematic ranges of the corners of the shoulder joint and its reflection on their athletic level, their return to the fastest period of time, and their activity again, "It is necessary to obtain a situation in which the main parts of the body are balanced and regular above the fulcrum and the organizational relationship between these parts Sound so that it can carry out its functions efficiently and with less effort".[11]

By reviewing the results, the researcher found that the improvement between the pre-test and the post test led to a remarkable improvement in the forward bending test, which the researcher attributes to that the rehabilitative exercises that contain different types of method of developing the range of motion before exercises of fixed and moving flexibility and the work of these exercises slowly and broadly Mobility helped in obtaining these results as (obtaining sufficient flexibility for the muscles, tendons, and ligaments of a particular joint or a group of joints in a particular movement or activity depends on the amount and intensity of the exercises that perform in a wide range of movement as well as on the degree of flexibility acquired prior to the individual) .[12]By reviewing the results, the researcher found that the significant change in the range of motion and passing most of the variables to the minimum range of the ideal range of motion to the effectiveness of the rehabilitative exercises on the proposed device in rehabilitating the affected area of the deltoid muscle because the exercises increase the body's flexibility and activity and increase the neuromuscular compatibility .[13]

We also note that the development of force resulted from the use of auxiliary means, where the researcher used, in addition to gradual physical pregnancy and exercises using weights gradient in the last weeks of the curriculum, which had a clear effect on the development and increase of strength. Future progress will be linked first of all, not to an increase in training reluctance. It will relate to the most effective selection of training method and how to focus on synthesizing training doses that achieve the best results, and this in itself will require accurate knowledge of the vital effects of the exercises used in training".[14]

Conclusions

1. Rehabilitation exercises have an effect by restoring the normal range of motion and flexibility of the deltoid muscle of the shoulder joint among the subjects of the research sample.
2. The development in the motor ranges of the shoulder joint is related to the disappearance of pain. Therefore, the positive effect of the rehabilitative approach in reducing or eliminating pain resulted in a clear improvement in the range of motion.

Human Folate Receptor-1 Gene Expression and Correlation with Physiological Leptin hormone in Obese and Non-obese Subjects

Areej GH Al-Charak[1], Hawraa H. Naji[2], Hamzah H. Kzar[2]

[1]Assis. Prof., Department of Physiology, Pharmacy, and Chemistry, Veterinary Medicine, Al-Qasim Green University, Iraq, [2]Lecturer, Department of Physiology, Pharmacy, and Chemistry, Veterinary Medicine, Al-Qasim Green University, Iraq

Abstract

Background: One of the most important agents that must be found in all dividing cells is folate.

Aim: Assessment of human folate receptor-1 gene expression and correlation with leptin hormone in obese and non-obese subjectsof Babylon province, Iraq.

Subjects and Method: This study included 60 obese subjects (OS) in the range of age (10-45 years) and 30 normal weight subjects (NOS) in range age of (11-43 years). FOR-1 gene expression were assessing by qRT-PCR after RNA extraction from fresh blood of all obese and normal subjects and immediately converting into cDNA. Leptin was assessed by ELISA method.

Results: The results suggesting that founds the positive correlation (r^2=0.447) between ages of OS and levels of LEP (ng/ml)**.** The results of this study showed significant differences (p-value< 0.05) in levels of leptin (LEP) between OS and NOS groups**.** The results showing that the FOR-1 gene expression ratio in NOS compare to expression OS were 11.9 and 7.1.

Conclusion: FOR-1 have a higher expression in OS compare to NOS and this may be useful in diagnostic and therapeutic tools in diseases or cancers in OS.

Keywords: *Obese subject, non-obese subject, leptin, folate receptor-1, SNP.*

Introduction

Acomplex, multifactorial, and largely preventable disease is called obesity[1]. It is typically defined quite simply as excess body weight for height and this simple definition contradict with an etiologically complex phenotype primarily associated with excess adiposity, or body fatness, that can manifest metabolically and not just in terms of body size[2]. One of the most important agents that must be found in all dividing cells is folate. It is one of the importance factors from providing methyl groups for remethylation of homocysteine (Hcy) to methionine and through Sadenosylmethionine (SAM) for one-carbon metabolism, providing cofactors for the synthesis of purines, phospholipids, and certain amino acids[3]. Kamen B et al (2004) has been reported that the folate receptor-1 (FOR-1) has high affinity for serum folate by 100-200 times than reduced folate carriers[4]. The gene for folate receptor, named FOLR1, consists of seven exons and spans over 6.7 kbp[5]. The polypeptide hormone that is produced by adipose tissues in proportion to their triglyceride content, links changes in body energy (fat) stores to adaptive responses in the central control of energy balance[6]. The major physiologic role

e-mail: hamza14shukri72@gmail.com

of LEP is to respond to and defend against reductions of body fat (and thus leptin) that might impair survival and reproductive fitness, evolutionary considerations, together with a large body of experimental data, indicate that[7]. The aim of this work is assessment of human folate receptor-1 gene expression and correlation with leptin hormone in obese and non-obese subjects of Babylon province, Iraq.

Material and Method

Study Design: This study included 60 obese subjects (OS) in the range of age (10-45 years) and 30 normal weight subjects (NOS) in range age of (11-43 years). FOR-1 gene expression were assessing by qRT-PCR after RNA extraction from fresh blood of all obese and normal subjects and immediately converting into cDNA.

Determination of LEP hormone levels: LEP levels were measured by using ELISA kit and the method performed depending on the manufacturer's protocol.

Gene expression analysis: PCR was carried out in a total volume 25 µl of reaction mixture with Taqman polymerase and carried by the thermocycler (Exycycler 96, bioneer, Korea) and subjected to denaturation at 95 C° for 3 min, followed by 30 cycles of 95 C° for 20 sec, 58.5 C° for 45 sec and the final extension phase at 72 C° for 7 min.

Results

Clinical characteristics of OS group is shown in table 1:

Table 1: Clinical characteristics of Obese Subject group

Clinical Variables	No. Total=60	Percentage (%)
Age		
10-25	22	37
26-45	38	63
Gender		
Male	37	62
Female	23	38
Education status		
Yes	29	48
No	31	52
Dwelling		
Rural	33	55
Urban	27	45

The results of this study showed significant differences (p-value< 0.05) in levels of leptin (LEP) between OS and NOS groups, as show in table 2:

Table 2: LEP levels in study groups

Groups	LEP (ng/ml) Mean± SD	P-value
OS n = 60	17.9±1.7	0.0000
NOS n = 30	11.9±1.3	

The results suggesting that founds the positive correlation (r^2=0.447) between ages of OS and levels of LEP (ng/ml), as shows in figure 1:

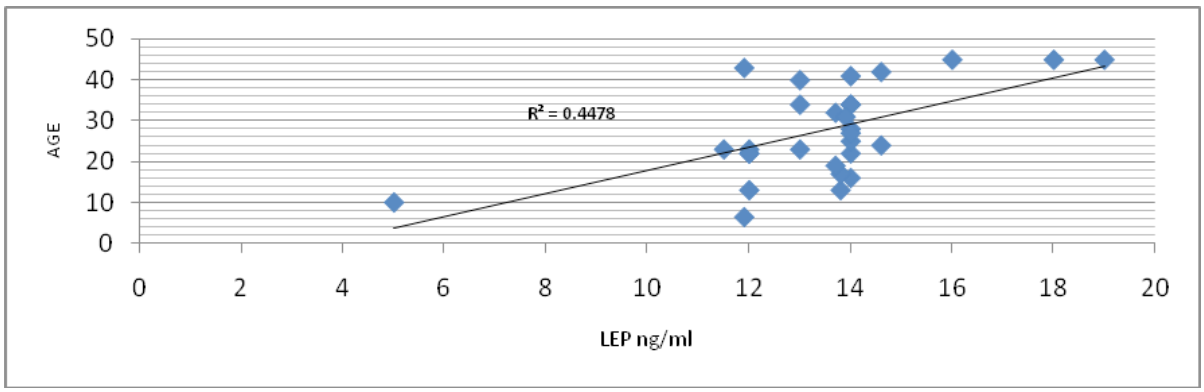

Figure (1): Correlation between ages of OS with LEP levels

The gene expression analysis of target and reference genes based on estimation of threshold value (Ct) for real amplification of gene of interest (GOI), FOR-1 (Genbank ID: NM2348, 6614 nucleotides) and housekeeping gene (HKG), GAPDH (Genbank ID: NM_002046, 1005 nucleotides) in OS and NOS groups. The Ct value was calculated as average of triplicate, The amplification and melting curves of FOR-1 gene expression is shown in figure 2:

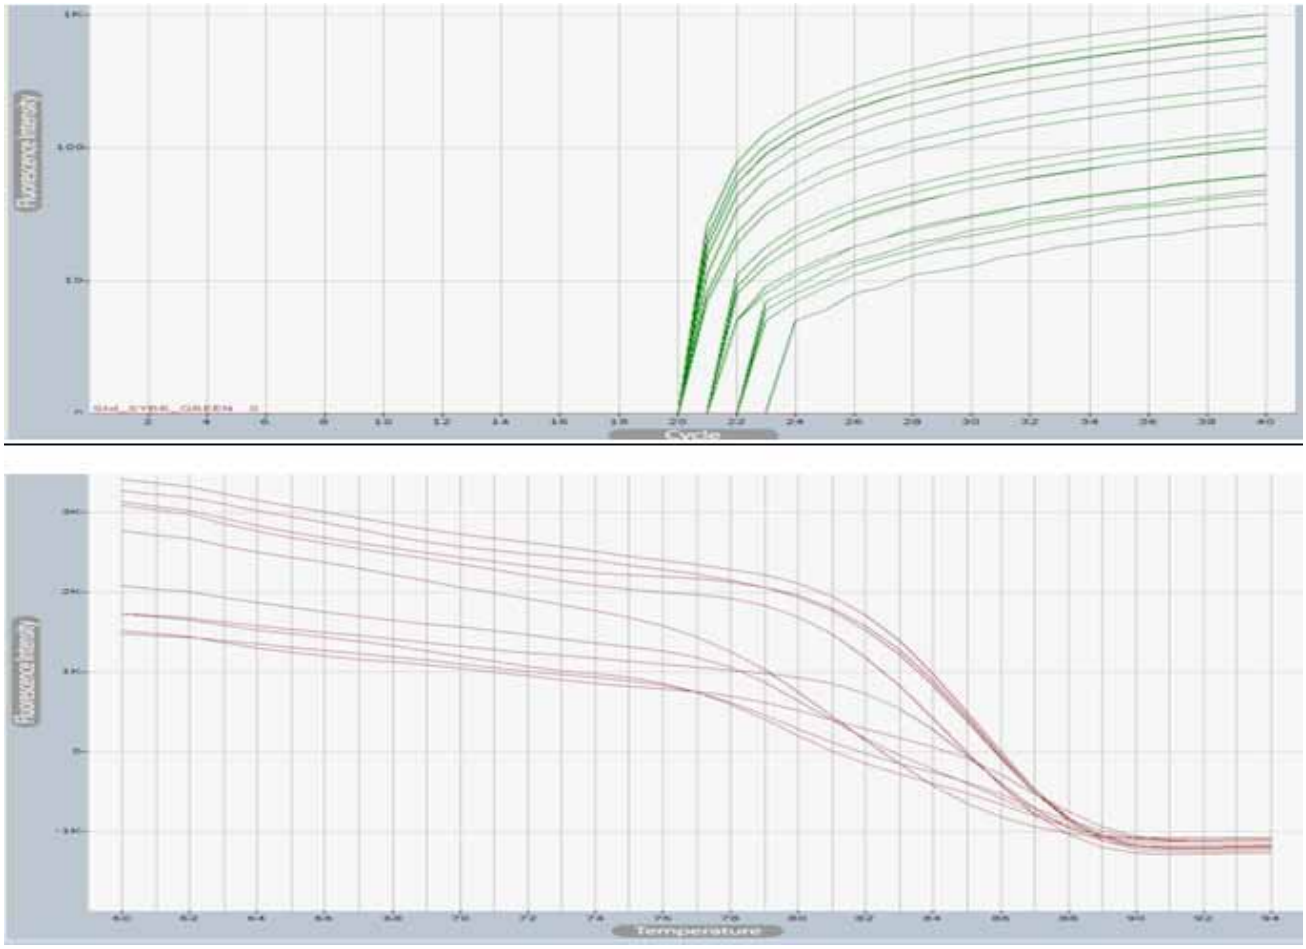

Figure 2:The amplification and melting curves of FOLR-1 gene expression in OS and NOS groups

The results showing that the FOR-1 gene expression ratio in NOS compare to expression OS were 11.9 and 7.1. is show in table 3:

Table 3: FOR-1 gene expression ratio in OS compare to expression NOS

Gene	Type of case	Efficiency %	GEF	p-value
FOR-1/GAPDH	OS	80	7.1	0.000
FOR-1/GAPDH	NOS	93	11.9	

Discussion

The tumor-associated antigen that binds folate and folate drug conjugates with very high affinity and shuttles is FOLR-1and these bound molecules inside cells via specific way called an endocytic mechanism[8]. Folate Receptor-1 (FOR-1), Proton Coupled Folate Transporter (PCFT), and Reduced Folate Carrier (RFC) are the cellular uptake of folate considered a specific transport mechanisms[9]. The receptor-mediated endocytosis/exocytosis is FOR-1 transporter for folate and functions at a neutral to mildly acidic pH. The

mediates of the co-transport PCFT, has optimal activity at low pH and, accounts for the low pH folate transport activity in the intestine[10,11]. This study not agree with study carried by *Carter et al., 2011* that say that fetal folate concentrations were similar in obese women as compared with normal weight women. Protein expression of FOR-1 in microvillus membranes was increased (+173%), in RFC was decreased (-41%), and in PCFT was unchanged. However, activity of FOR-1, PCFT, and RFC was unaltered in obesity[12]. The results of this study showed significant differences (p-value< 0.05) in levels of leptin (LEP) between OS and NOS groups. *Myers et al., 2010* give an example is the finding that leptin overexpression in OS, which initially promotes leanness, results in increased adiposity in the long-term and this not agreement with the results of present study [13]. The following up of obese subjects more easy by estimation the LEP hormone and this agree with study that say of the progression and responding to chemotherapy treatment may be moreeasy by estimation the glucose transporting, angiogenesis, and apoptotic markers in women with BC[14]. Moreover, this study suggested that higher levels of LEP are associated with increased folate receptor gene expression in obese subjects. The results also showing that the FOR-1 gene expression ratio in NOS compare to expression OS were 11.9 and 7.1. In conclusion the results suggested that FOR-1 have a higher expression in NOS compare to OS and this may be useful in diagnostic and therapeutic tools in diseases or cancers compare toNOS.

EV Targeting MCF-7 Breast Cancer Cell Lines Inhibit Both mTOR and HIF-1A: Molecular Docking Study

Haider O. Mossa Al-Gazali[1], Hamzah H. Kzar[2], Moshtak A. Wtwt[3], Moaed E. Al-Gazally[4]

[1]Dr. Ministry of Health, Al-Qasim General Hospital, [2]Lecturer, Veterinary Medicine Collage, Al-Qasim Green University, Iraq, [3]Prof., Collage of Medicine, University of Babylon, Iraq, [4]Prof.,Collage of Medicine, Babylon university (Work Now at University of Al-Ameed), Iraq

Abstract

Background and Objective: The mortality dramatically increase in breast cancer are caused by inadequate of the benefits of different types of therapies. mTOR is an atypical serine/threonine protein kinase that belongs to the phosphoinositide 3-kinase (PI3K)-related kinase family. The aim of this study to investigation of ability of EV to inhibiting both mTOR and HIF-1A through MCF-7 BC cell lines targeting and docking study by specific computational program.

Method: In vitro cytotoxicity study of different doses of EV were quantitatively measured by employing on MCF-7 cell lines. Docking study was done by computing 3D programs (in silico), the information in protein data bank (PDB) Zinc15docking and phyre2 protein homology tools.

Results: There was another suggestion for inhibition of HIF-1A protein (PDB reference code 4AJY) by incubation of MCF-7 cells with 5 mg/day of EV that is may be binding of EV as analogue in other sites differs from active site and may be stimulate the hydroxylation and acetylation of the protein and enhanced normal degradation pathway.

Conclusion: This study suggesting the mechanism of inhibition of HIF-1A by EV in addition to inhibition of mTOR pathway.

Keywords: *Breast Cancer, mTOR, HIF-1A, Everolimus, Docking.*

Introduction

Mammalian target of rapamycin (mTOR) is a protein kinase that regulates proteinsynthesis and cell growth in response to growth factors, nutrients, energy levels, andstress[1]. mTOR is an atypical serine/threonine protein kinase that belongs to the phosphoinositide 3-kinase (PI3K)-related kinasefamily and interacts with several proteins to form two distinct complexes named mTORcomplex 1 (mTORC1) and 2 (mTORC2)[2]. The mTOR signaling pathway plays an essential role in cell growthand proliferation by coordinating anabolic processes with oxygen,energy and nutrient availability, as well as extracellular cues. Onefundamental characteristic of cancer cells resides in their ability tosustain chronic proliferation in the absence of growth-promoting signals. This proliferative advantage is achieved, at least in part, bygenetic events that cause aberrant activation of mTORC1 signaling[3]. Indeed, mTORC1 lies downstream of the Ras/MAPK and PI3K/Akt signaling pathways, where gain-of-function mutations inRas, Raf, PI3K and Akt oncogenes, and loss-of-function mutationsin the tumor suppressors neurofibromatosis-related protein-1 (NF-1), phosphatase and tensin homolog (PTEN) are found inup to 80% of human cancers[4]. Themajority of catalytic mTOR inhibitors is currently in phase I clinicaltrial,

Hamzah H. Kzar
Lecturer, Veterinary Medicine Collage, Al-Qasim Green University, Iraq
e-mail: hamza14shukri72@gmail.com

and these compounds are being tested as single agents or incombination with other chemotherapeutic agents. Currently, these compounds are being tested against several types of cancer, includingbreast cancer, endometrial cancer, non-Hodgkin lymphoma and advanced stages of solid tumors [5]. The HIF-1A subunit has two transactivation domains (TAD): NH2-terminal (N-TAD) and COOH-terminal (C-TAD). These two domains are responsible for HIF-1A transcriptional activity [6]. C- TAD interacts with co-activators such as CBP/p300 to modulate gene transcription of HIF-1A under hypoxia. N-TAD is responsible for stabilizing HIF-1A against degradation [7]. Moreover, all HIF-1A subunits are distinct from HIF-1B in that they all have an oxygen- dependent degradation domain (ODDD) over lapping N-TAD in their structures . This ODDD domain is important in mediating O2 regulation stability [8]. Given that cells and organs need to adapt to changes inoxygen supply, it would not be surprising to find that asignificant variety of the HIF-1 target genes are regulated ina tissue-specific manner. To date, there are more than 100HIF-1A downstream genes identified with varying functions(Table 1.2). HIF-1A activates the expression of these genes bybinding to HRE located in theirenhancer and promoter regions[9]. Everolimus (RAD001(40-O-(2-hydroxyethyl)-rapamycin))(molecular weight, 958.2 g/mol) is an orally active derivative of rapamycin that inhibits the Ser/Thr kinase, mTOR[10]. The aim of this study to investigation of ability of EV to inhibiting both mTOR and HIF-1A through MCF-7 BC cell lines targeting and docking study by specific computational program.

Materials and Method

***In vitro* cytotoxicity effect of EV on MCF-7 BC cell lines.**

1. In vitro cytotoxicity study of different doses of EV were quantitatively measured by employing on MCF-7 cell lines.
2. MCF-7cells were cultivated in RPMI 1640 medium supplemented with 10% FBS and 1% penicillin/ streptomycin, non-essential amino acids (0.1 mM), insulin (10 ug/mL) and sodium pyruvate (1 mM) at 37 Cº in incubator with 5% CO^2.
3. The cells were seeded in 96-well plate for 1 day, 2 days, and 3 days and then the medium was changed with various concentrations of EV(1,10,20, 40,100 mg/dl).
4. In vitro cell viability was determined using the MTT assay as described in following:

MTT protocol (1 day):

a. The cells(1×10^4 cells/well) were seeds in 96-well plate with culture medium in final volume of 100 µl/ well.

b. The plate was incubated at 37C° (5% CO_2 incubator) for 1 day hr.

c. Cells were then treated with various conc. of EV for one day at 37C° in a 5% CO2 incubator.

d. One hundred of fresh medium were added.

e. Ten µl of MTT reagent were add to each wells of plate.

f. The plate was incubated at 37°C in a 5% CO2 incubator for 4 hr.

g. The medium was carefully removed from wells

h. Two hundredµl of DMSO was add to wells and mixed to dissolving all crystals and incubated for 30 min.

i. The absorbance has been reads at 540 nm.

j. Untreated cells represent the control cells (not exposed to EV).

Percentage of viability and cytotoxicity **Cell viability (%) = (Abs_{540} Treated cells/Abs_{540} Control cells) × 100, Cytotoxicity (%)= 100- Cell viability%**

Results and Discussion

Cytotoxicity study: Figure 1 showing the MCF-7 cell viability % between EV at given concentrations and control during 1, 2,and 3 days of period of incubation:

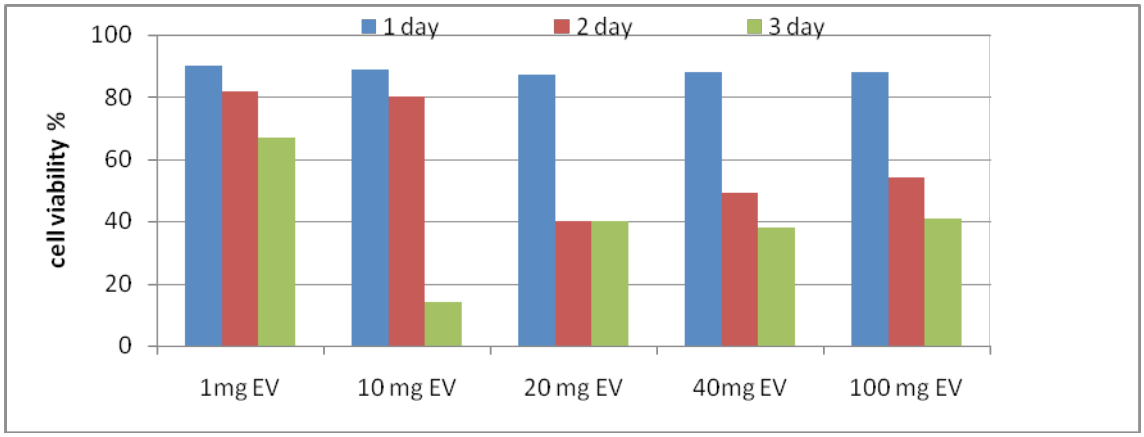

Figure (1): Viability of MCF-7 BC cell lines cultured with EVin different conc. at 1, 2, and 3 days incubation time, the values are mean (n=3) ± SD.

MTT assay is one of the common assays used to study cell viability and proliferation. It depends on the ability of viable cells to reduce the yellow MTT dye to insoluble purple formazan crystals. Here, MTT assays were used to study the anti-proliferative activity of EV on MCF-7 cell lines. The results of present study showing that no statistical differences in cell viability % when incubation of EV free with MCF-7 cell lines at one and second day of period of incubation (92±5, 82±4) (p-value>0.05), but the results show significant differences between one and third day of incubation time (91±2, 65±3) (p-value<0.05). The results also showing highly statistically differences in cytotoxicity% when incubation 10 mg of EV with MCF-7 BC cell lines at three day of incubation (10±1) (p-value< 0.001). The chemical structure of EV has more than one hydroxyl groups and this may be facilitated of binding with HIF-1A leading to inhibitory effects. It was reported by *Greenberger L et al*., (2008) that inhibition of HIF-1A by EZN-2698 attenuates HIF-1A protein level and tumor progression in various in vitro (human prostate and glioblastoma cell lines) and in vivo studies[11]. *Georgina N et al*., (2015) were reported anthracyclinesare the potent well-known chemotherapeutic agents, alsoactasHIF-1A inhibitors by preventing to binding with DNA [12].Another novel class of molecularly targeted anticancer agents consists of inhibitors of heat shock protein 90 (HSP90), such as geldanamycin, 17-allylaminogeldanamycin (17-AAG) and 17-dimethylaminoethylamino-17-demethoxygeldanamycin, which target HIF-1A forproteasomal degradation[13]. A number of HIF-1A inhibitors have been synthesized or discovered for treating cancer, particularly for advanced and refractory solid tumors. They inhibit the expression and/or functions of HIF-1A through direct and indirect mechanisms.

Molecular docking study

By application molecular docking study and Ligand-based drug design (protein-ligand interaction) of online computing 3D programs (in silico) (https://www.rcsb.org), the information in protein data bank (PDB) (https://www.pdb.org/),https://pubchem.ncbi.nlm.nih.gov,Zinc15.docking and phyre2 protein homology tools there was another suggestion for inhibition of HIF-1A protein (PDB reference code 4AJY) that is may be due to binding of EV as analogue in other sites differs from active site and may be stimulate the hydroxylation and acetylation of the protein and enhanced normal degradation pathway or may be formation the HIF-1A-EV complex that preventing of translocation of HIF-1A into nucleus to binding with HIF-1B and in turn inhibition the controlling of HIF1A-HIF-1B dimer on gene expression of target genes, as showing in figure 1:

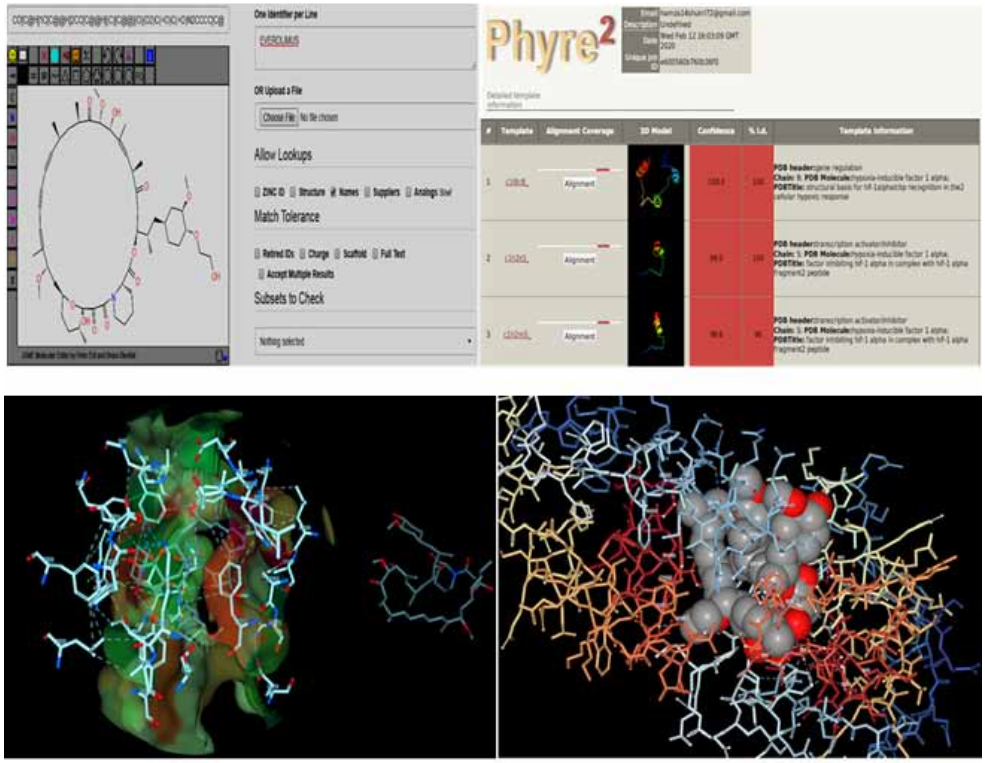

Figure (1): A-Zinc15. docking website for drawing EV structure B-Phyre2 protein homology tool results

The amino acids sequence of HIF-1A protein is shown in figure 2:

Figure (2): Amino acids sequence of HIF-1A protein

To date, no study have reported that HIF-1A are inhibit by EV. This study reported for the first time about the interactions between EV loaded NPs and HIF-1A. It can be concluded that EV loaded NPs had the potential of inhibiting HIF-1A activity. The molecular protein-ligand docking study suggestion that five amino acids participate in this interaction, the residues were (Asn 670, Phe 540, Val 599, Tyr 522, and Lys 629) participating in hydrogen bonding while the residues (Thr 611, His 646, Lys 719, Trp 752) (4 bonds) forming van-der Waalsinteractions between protein (HIF-1A) and ligand (EV) with high binding energy -12.2334 kcal/mol. Active binding sites of EV and HIF-1A protein depending on type of interactions is shown in table-1:

Many of the novel anticancer drugs that target specific pathways have been shown to have anti-angiogenic effects that appear to be inhibition of HIF-1A activity, as shown in table-2:

Table(1): Active binding sites of EV and HIF-1A protein depending on type of interactions

Target protein (HIF1-A)	Active binding sites	Binding affinity energy
Hydrogen bonding	Asn 670, Phe 540, Val 599, Tyr 522, and Lys 629	-12.2334 kcal/mol
Van-der Waals interactions	Thr 611, His 646, Lys 719, Trp 752	

Table (2): Selected drugs that inhibit HIF-1A activity

Drug	Effect	Reference
Doxorubicin	Decreased HIF-1A DNA binding	[14]
Cetuximab	Decreased HIF-1A synthesis	[15]
Digoxin	Decreased HIF-1A synthesis	[16]
Trichostatin A	increased HIF-1A degradation	[17]
Allylaminogeldanamycin.	Decreased HIF-1A transactivation	[18]
Taxotere	Decreased HIF-1A synthesis	[19]
Bortezomib	Decreased HIF-1A transactivation	[20]
EZN-2968 Topotecan	Inhibit HIF-1A mRNA expression Inhibit HIF-1A mRNA translation	[21] [22]
Everolims	Inhibit HIF-1A mRNA expression	This study

In present study, when HIF-1A mRNA expression decreasing by incubation with EV (10 mg)and in results declines the levels of GLUT-1,CD44 and VEGF (the results not appear in this paper)[23], and this means that the transcription process may be inhibited and all events after this may be not occurs. This events are due to blocking of proteins those responsible on transcription of HIF-1A mRNA such as transcription factors by EV and decrease levels of HIF-1A and in turn prevent translocation it to nucleus and don't binding with HIF-1B on its response elements on DNA. Other explanation is may be due to prevent the signals such as growth factors to binding on its receptors on cell membrane by blocking this receptors and this need further investigations.

Cellular targets of biological signals in development for BC through hypoxia events. EV free can be inhibit of mTOR, EV loaded NPs can be inhibit of both mTOR and HIF-1A mRNA and protein and in turn controlling on gene expression of target genes through prevent the accumulation, translocation, and binding of HIF-1A with nucleus protein (HIF-1B). The suggested schematic diagram can be summarize all the findings elucidated by the current study, as shown in figure 3:

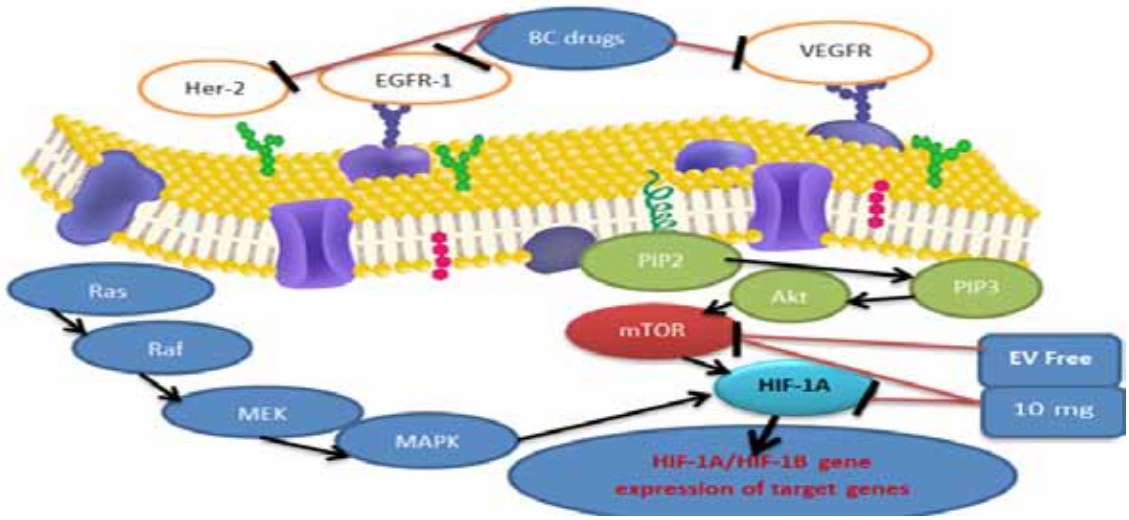

Figure (3): Cellular targets of biological signals in development for BC through hypoxia events: EV inhibit both mTOR and HIF-1A.

Conclusion

Suggesting the mechanism of inhibition of HIF-1A by EV in addition to inhibition of mTOR pathway

Road Traffic Accidents and the Traumatic Brain Injuries: A Cross- Sectional Study.

Ali Abbas Hashim Al musawi[1], Hasan Alwan Baiee[2]

[1]Lecturer, [2]Prof., University of Babylon–Hammurabi College of Medicine/Iraq

Abstract

Background: Street traffic accidents were a main community healthiness problematic particularly in low and middle-income countries, head injuries were found to be the most common injuries. Objectives: to identify the relationship of road traffic injuries with different associated factors.

Methodology: This was a cross sectional study conducted on 500 Road Traffic Accidents victims admitted to the emergency unit at Al-Sader Teaching General Hospital in Al Najaf Holy province- Iraq. Data collection was done using a pretested questionnaire. A medical team including neurosurgeon, medical, and orthopedics to identify the types (pattern) of cranio-cerebral injuries evaluated outcomes of the injury cases.

Results: Most of the victims are males in their productive age, motorcycle is the most common cause of accidents, head injuries constituted the highest proportion (39.6%), the mortality rate was (13.6%), and unhealthy behaviors during driving were dominated.

Conclusion: Cerebral contusions and skull fractures were the most common lesions among head injuries and trauma brain injuries victims.

Keywords: *Road Traffic Accidents, traumatic brain injuries, driving behavior–Al-Najaf province Iraq.*

Introduction

Globally, nearly 3 400 people die on the world's roads every day. Tens of millions of people are injured or disabled every year. WHO works to raise the profile of the preventability of road traffic injuries[(1)]. WHO article guesses that 1.9 million individuals in the world die yearly by 2020[(2)], deaths due to street traffic damages occur in little and middle-income nations[(3,4)]. Road traffic crashes cost most countries 3% of their gross domestic product [(5)]. In 2020, the 3rd reason of death and morbidity. 50% of the dead are persons with in their productive age [(6)]. The straight and unintended prices advanced in developing republics likened to those in developed republics[(7)]. Rendering to WHO, the typicalyearly mortality rate due to street traffic damage in Iraq is 44.7 (consistent age mortality rate per 100,000 people) [(8)]. Road traffic injuries cause estimated 700 deaths among young people every day [(9)]. Head injuries due to Road Traffic Accidents is a recognized health problem causing death and disability among the victims, the head being the most vulnerable part of the body that is why cranio-cerebral injury is on the top[(10-12)]. The objectives of this study are to identify the relationship of road traffic injuries with different associated factors, and to assess the morbidity and mortality among road traffic victims admitted to the emergency unit of Al- Sadder hospital-AL-Najaf province- Iraq during the year 2016.

Methodology

Approval of research ethical committee of Al- Najaf health directorate was obtained; verbal consents were taken from patients or their companions after explaining the objective the study. This study was a cross-sectional study conducted in Al –sadder medical city in Al-Najaf province – Iraq, the duration of this study started from

the beginning of September –to the end of November 2016. The study group included all patients who were admitted to the emergency unit in Al-Sader general hospital who were injured due to Road Traffic Accidents. Exclusion criteria of this study include victims of Road Traffic Injuries (RTIs) that took place in other provinces and admitted for treatment in this general hospital; any RTI occurred on the road without involvement of automobile (e.g. a person falling due to slipping on the road and causing injury) or injury involving not moving vehicle (e.g. when persons injured while washing or repairing a vehicle) [13]. Interviewing of patients and or their companions was done by the research team using pretested questionnaire which included: demographic information (age, gender, educational level..etc.), site of injuries, time of accident, driving behavior (having driving license, wearing seat belt and wearing helmets for motorcyclists). Data were completed by reviewing the records of accidents surveillance program and forensic department records. Outcomes of the injury cases were evaluated by a medical team including neurosurgeon, medical, and orthopedics to identify the types (pattern) of cranio-cerebral injuries through Computer Tomography findings like skull fractures, parenchymal injuries, intracranial hemorrhages, and discharge outcome (alive or death). and calculating the case fatalities together with the proportionate mortality ratios through following up cases during the period of the study. Data were analyzed by using descriptive presentation contain classical Chi-square to test association between the variations by using SPSS version 21 The $P \leq 0.05$ is considered statistically significant.

Results

Table (1) explains that male to female ratio equal to 5:1 and most of victims in age group (20-29 years). Males outnumbered significantly females p<0001.

Table (2) reveals that one fourth of the victims are illiterates and about two thirds of them are below the primary school level.

Table (3) shows that the main vehicles causing RTIs in Al-Najaf province was caused by motorcycle (30%) followed by private cars (29%).

Table (4) depicts the time of occurrence of accidents; the highest rate of accidents took place between (9-11 am).

Table (5) shows that out of 217 injured drivers only (29,1%) have driving license. Among 126 drivers accepted to answer the question of wearing seat belt (9.5%) use the seat belt regularly, while none of the (98) motorcycle drivers (0%) mentioned that they used helmet during driving. Table (6) explains that the main site of injury is head (39.6%).

Discussion

RTIs are the leading cause of injuries, account for 27% of the total injury and violence mortality in the Eastern Mediterranean Region [14]. The current study depicts that males are the predominant victims and in their productive age, these findings are similar to the findings of other studies in Iraq [15,21] and in other countries [22- 28], this could be explained by the fact of high occupational exposure of males to road using and the lack of road safety in the province together with the congested roads of this holy city especially during religious visiting events. Most of the victims have low levels of educations this finding goes in line with other studies [18,19] . This finding is also similar to other study conducted in Yazad-Iran [28]. The majority of RTI occurred among motorcyclists this finding agrees with the findings of other study conducted in Yemen [25] and in Nepal [27], this study identifies that no motorcyclists used helmets, while in a study conducted in Kenya helmets were used by less than one third of motorcycle drivers [29] motorcyclists not wearing this protective device are especially vulnerable for severe head injuries [30]. The majority of RTIs took place in the daytime mainly at 9 to 12am and 12am to 2pm this finding is similar to a study conducted In Iran [31]The most frequently injured body regions as reported in this study was the head, followed by lower extremities this finding is in contrast with findings of other researchers[32], but it goes with the finding of other studies [27.33]. Several studies reported that head injury was found to be most common injuries during traffic accidents [34],being 42.1% making a substantial contribution to RTA cases[35], the main reasons of the fatality is severe traumatic brain injury (TBI) produced by head dullpowers[36,37]. In low- and middle-income countries 43% of individuals with TBI that cause by cars accidents[39]. Although numerous studies have been done, the consequence of skull fracture on TBIs has not been obviously assumed[14]. In the current study the types of lesions are; contusions followed by skull fractures then lacerations this findings are in contrast with report of Pathak et al [34] who found that contusion constitutes 5.16% and skull fracture 22.7%, this difference may be related to difference in the severity of traumas due to RTA in our study or may be due to the poor use of the seat belts and helmets. The current study shows that less than one third of drivers have driving license and less than (10%) of drivers wear seatbelts regularly, findings indicate bad road behavior and they are less than that reported by other studies[11,27,33]. As a result of the enactment of the seat belt law, in accordance with suggestions from many studies, a significant drop in certain types of injuries[32].

Most of the victims are males in their productive age, motorcycle is the most common cause of accidents, and head injuries constituted the highest proportion, unhealthy behaviors during driving dominated.

Frequency of Left Ventricle Dysfunction in non-Alcoholic Fatty Liver Disease (NAFLD) Patients Detected by Global Longitudinal Strain and Tissue Doppler Imaging in Babylon Province in Iraq

Haitham Shaalan Sewan[1], Hassan Salim Aljumaily[2]

[1]Dr. Researcher, Diploma of Internal medicine, Babylon Health Director, Iraq,
[2]Prof., Dr. College of Medicine, Babylon University, Iraq

Abstract

The aim of the study is an assessment of left ventricle systolic and diastolic function in patients with non-alcoholic fatty liver disease (NAFLD) by measuring global longitudinal strain, and tissue Doppler imaging TDI.

Method: A Case-control study enrolled 30 patients with non-alcoholic fatty liver disease (mean age 44.13 years) without a history of cardiac disease and 30 healthy controls (mean age 44.79 years). All participants had been undergone trans-thoracic echocardiography (TTE), tissue Doppler imaging (TDI) for assessment of mitral annular systolic velocity (S`), E/A ratio, and E/e', as well as left ventricle global longitudinal strain (GLS) using speckle tracking echocardiography (STE) technique.

Results: NAFLD patients had shown The E/e' ratio was significantly higher in the NAFLD group (9.86± 1.69 vs 6.85 ±1.23),(P = < 0.001) . The difference in the E/A ratio between the groups was significant (P = 0.04). GLS was also significantly lower negative in NAFLD patients in comparison with control (-18.85± 1.07 vs -23.05 % ± 1.19) but within normal values.

Conclusion: There is an increasing risk of subclinical LV dysfunction (systolic and diastolic)in NAFLD patientscan be early confirmed by DTI and GLS.

Keywords: *Left ventricle dysfunction, non-alcoholic fatty liver disease (NAFLD), global longitudinal strain, Doppler imaging, Babylon province.*

Introduction

One of the most chronic liver diseases worldwide is a non-alcoholic fatty liver disease (NAFLD) with hepatocytes infiltration by fatty deposit, its prevalence between 25% and 30 in the united states affecting all groups of age, suggestinga serious and growing problem[(1)(2)]. NAFLD involves a wide spectrum of liver disease inflammation coexist following simple steatosis with different stages of fibrosis reach to hepatic cirrhosis and hepatocellular carcinoma HCC. Non-alcoholic steatohepatitis (NASH) is a subtype of disease progression indicating the extreme form of NAFLD. NAFLD is significantly associated with increased morbidly and mortalitydue to cardiovascular events[(1)]. The dysfunction of adipose tissue there is what is calledadipokine secretion that relates to overweight and obesity which leads to a wide spectrum of diseases mainly cardiovascular disease,although some adipokines have anti-inflammatory andgive protection against cardiovascular complications.[(1)]. Sub-clinical defects, CAD, LV, hypertrophy, HF, HHD, and arrhythmias are found in cardiovascular

diseases. The discharge of mixture mediators including pro-inflammatory, procoagulant, and profibrogenic mediators is involved in the association of atherogenic dyslipidemia, systemic and Hepatic insulin resistance with obesity and hypertension[2][3][4]. In addition to the history of alcohol use (the appropriate limits of alcohol intake are 70g/week for females and 140 g/week for men), the over nutrition shows central obesity, primarily overweight persons make abdomen ultrasound with fatty changes, a diagnosis of NAFLD,and diagnosis for other liver diseases should be excluded. Although alcohol consumption in low amounts can be protected from complications, the estimated mortality is 1.6-fold. The lifestyle modification through a decrease weight of > 7% is less than 50%. The control of serum lipid is important to decrease the danger of cardiovascular diseases in NAFLD[5]. Although liver biopsy is the only effective way to distinguish NASH from NASH in NAFLD, a more new development in a noninvasive way is also possible. Even In the absence of obesity which is morbid, high blood pressure and hyperglycemia, NAFLD may cause impairment of LV function whether diastolic or systolic[6]. Speckle-tracking echocardiography (STE) isa new ultrasound technique that is a non-invasive by which we can do an evaluation,quantitively or objectively for the regional and global function of the myocardium[7][8].several studies show that the GLS was significantly reduced in NAFLD [9]. The exact mechanism of LV dysfunction is not well known yet, but the mean pathophysiological landmark is the resistance of insulin secretionwhich is mainly seen in non-alcoholic fatty liver disease (NAFLD), although the same process had been seen in patients of essential hypertension [10]. In control subjects without hepatic steatosis, NAFLD patients show atherosclerosis of high prevalence [11]

Method

A case-control study, done at Marjan city Teaching hospital, echocardiography unit,with the cooperation of the GIT disease unit and radiology unit for the period from 1st January to 1stMarch 2020. The case-control study included 30 outpatients individuals aged more than 18 years old with NAFLD, 16 females and 14 males. These individuals referred from ultrasound units in Merjan Medical city accidentally found to have fatty liver changes and all of them are non-alcoholic most of them have overweight and obesity with irritable bowel syndrome or renal colic without chronic diseases. Healthy control without previous history of cardiac diseasethose are 30 include 25 females and 5 males, These individuals referred from ultrasound units in Merjan Medical city accidentally found to have fatty liver changes All patients and control underwent conventional echocardiography. The examination was established by using a "Vivid E9 echo machine from GE Healthcare Company with an M5Sc probe with multiple frequencies. The patients had been done in the left lateral position, and views and measurements had been taken according to American guidelines of Echocardiography. A 2-Dimension-speckle tracking strain and TDI had been done to 30 control and 30 of the patients. This study was done in Echo Department in Marjan teaching Medical City. The following patients were not involved in this study:

1. Diabetes Mellitus
2. Hypertensive
3. BMI > 40
4. IHD
5. CMP
6. Other CLD (chronic liver diseases)
7. History of using hepatotoxic drugs

All participants underwent 2-dimensional transthoracic echocardiography, incorporating STE using a Vivid E9 system (GE, Norway). All measurements of 2-D echocardiography were worked and analyzed by the echocardiologist who was blinded to the patient group assignment, depending on the recommendations by the American Society of Echocardiography last one [12]. The same ultrasound machine was used to acquire all echocardiograms. The function of the diastole of LV was determined by using pulse wave (PW) and TDI. By using M-mode the systolic, the dimensions of end-diastole and septal thickness of the ventricle had been calculated. ejection fraction of the left ventricle (LVEF), end-diastole and end-systole volume (EDV, ESV) had been measured with the 4-chambers and 2-chambers apical views, and the modified Simpson's biplane method had been used, which a method acquires the benefit of the enhancement in image inequality and in the ability to see the borders of endocardium clearly in end-systolic and end-diastolic views[13].Guidelines for use TDI to assess the diastolic function: by view of apex run pulse wave of TDI to get on annular velocities of the mitral valve, place the sample view at or 1 cm through the septal and lateral mitral leaflets, sweep the speed from 50 to 100 mm/s when expiration end, the

measure reveal the mean of three or more successive cycles, the measurements start with systolic, early (e'), and late (a') velocities of diastole, to assess entire LV diastolic function, the signals of tissue doppler obtain and calculate the lateral and septal sides of the annulus of the mitral valve and their mean, to outcome relaxation of LV on mitral E velocity, e' can be utilized for correction, and E/e' ratio (a marker of left atrial (LA) pressure)can be requested to predict the pressures of LV filling. The E/A ratio <1.5 along with both E/e' ratio <15 and e' velocity >8 cm/sec was considered as the normal diastolic function[14][15][9][11]. The E/é ratio is not a precise as an index of pressures filling in persons who are normal or patients with annular calcification that is heavy, disease of the mitral valve, and pericarditis that constrictive one[16]. By taking an apical 4 chamber view (4CV), PWD was put at the mitral valve tip and then the peak of E and A wave velocity was calculated in addition to measurements of E/A ratio. So the E/e' was measured automatically from the septaland lateral part of the annulus of the mitral valve. Then "Pulmonary capillary wedge pressure (PCWP)was measured by using this formula, PCWP= (E/e´ + 4).

LV Strain using Speckle Tracking Echocardiography (STE): The deformation analysis is an analytics issue of the shape and mechanics of the ventricles through the cardiac cycle. Deformation can be categorized by the strain of myocardium, rate of strain, and torsion, every one of them refers to a parameter difference in the change of shape during contractility and relaxation[17]. The Left ventricular GLS had been measured by the use of STE at the frame rate of 50 to 70 frames/s. It is recommended to begin with an apical three-chamber view (A3C) to choose the frame matching the aortic valve closure, the reference point corresponding to end-systole. In addition to this view, apical four chambers(A4C),and two-chamber view (A2C) which is necessary to complete the assessment. The GLS was automatically measured by the echo machine as an average of strain obtained from these three views. The normal value in a healthy person is around −20%, while it is abnormal if GLS more than -18 %. On 2-dimensional echocardiography, the GLS appeared the change of the myocardial length of the left ventricle (LV) propionates in-between end-diastole and end-systole. After optimization of the quality of the image, frame rate maximization, and minimization of foreshortening, the measurement of peak mid-wall GLS was taken in the standard of three views and AFI (automated function imaging) application had been averaged.[18] Analysis of statistics was carried out using SPSS version 23. variables category were obtained as frequencies and percentages. Continuous variables were presented as (Means ± SD). The student t-test was used to compare means between two groups. Chi-square test and Fisher-exact test were used to find the association between categorical variables. A p-value of ≤ 0.05 was considered significant.

Results

In this study, the results were expressed into 2 groups; Non-Alcoholic Fatty Liver disease (NAFLD) and normal control groups. 60 individuals were enrolled in the present study. The mean age of the participants was (44.6)and (47.2) years old in the case and control groups, respectively. Among the patients with NAFLD,(16) were male and (14) were female, with (5) male and (25) female in the control group. The E/e' ratio was significantly higher in the NAFLD group (9.86± 1.69 vs 6.85 ±1.23), P ≤ 0.001). The difference in the E/A ratio between the groups was significant (P = 0.04). GLS was significantly lower negative in NAFLD patients t in comparison with control (-18.85± 1.07 vs -23.05 % ± 1.19) but within normal values. LVEF was statistically insignificant between the groups. Regarding the lipid profile, the study failed to show a significant difference in Total cholesterol, S.TG, HDL, and LDL between NAFLD and the control group.

Table 1. The demographic characteristics of the participants and lipid profile.

Study variables	Control group n=30		NAFLD n= 30		P-value

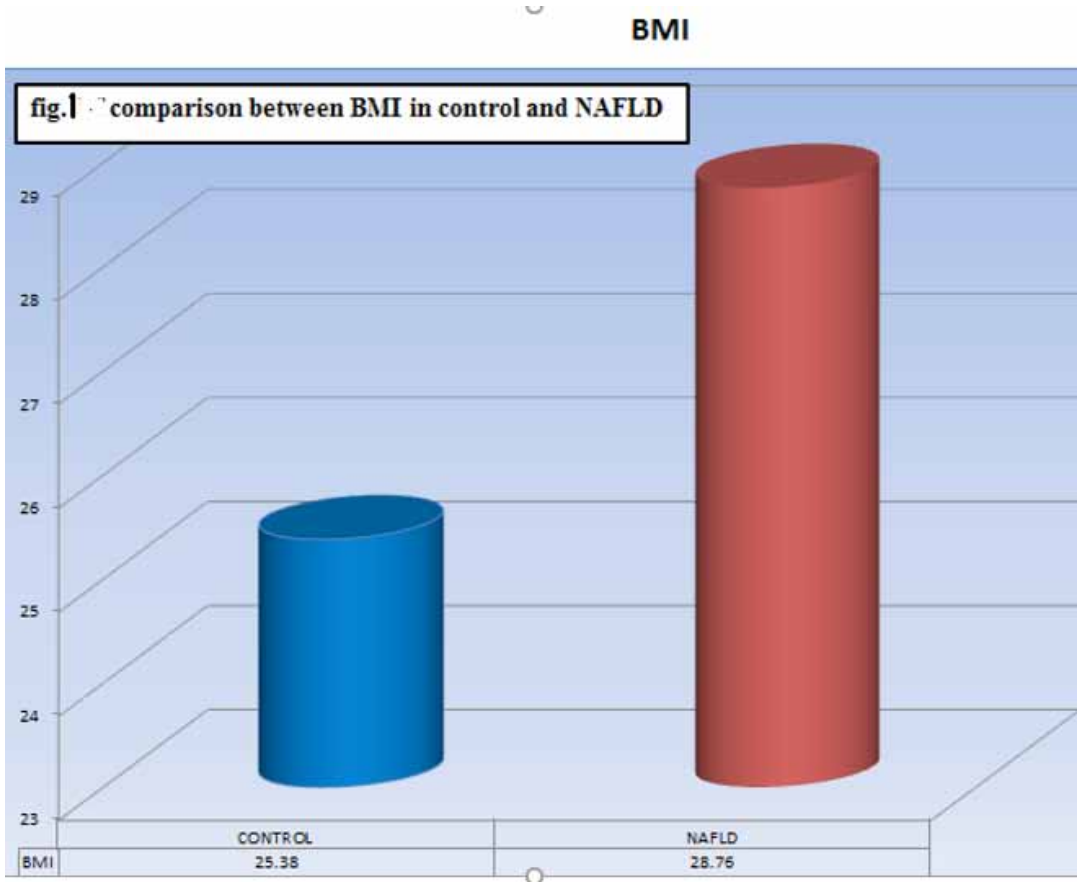

Figure 1: Comparison of BMI between NAFLD and Control group

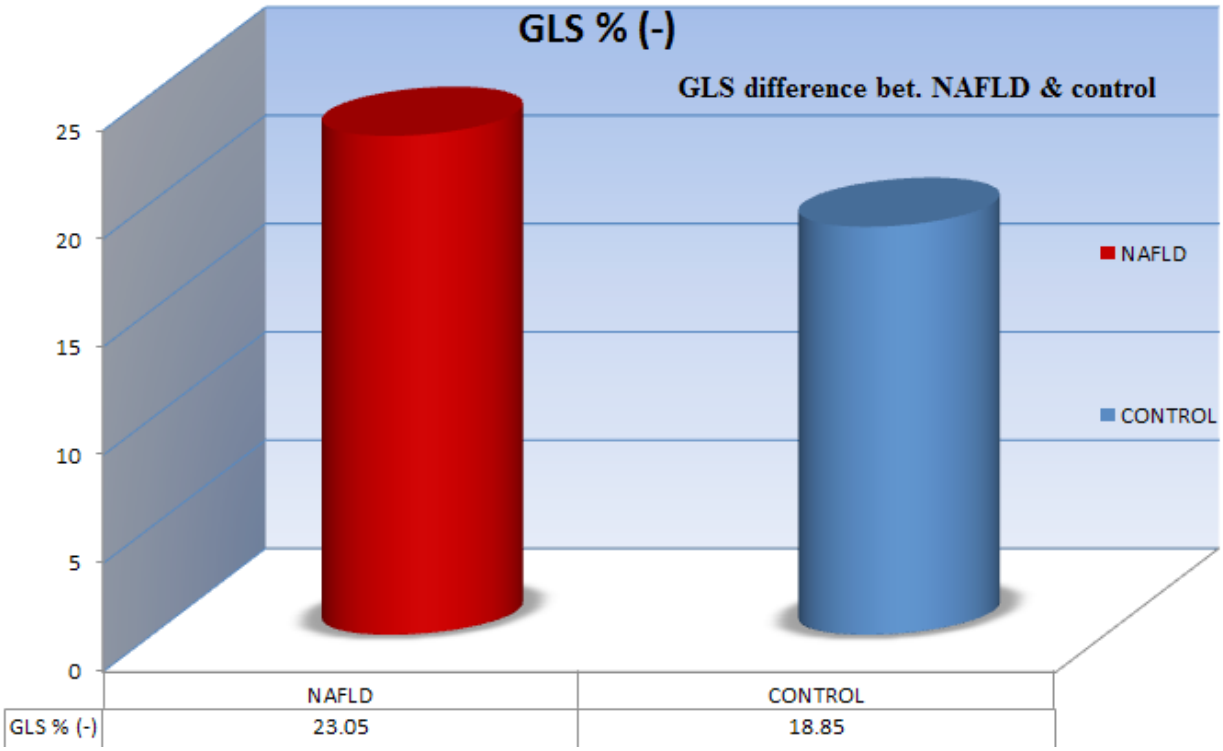

Figure 2. GLS difference between NAFLD and Control

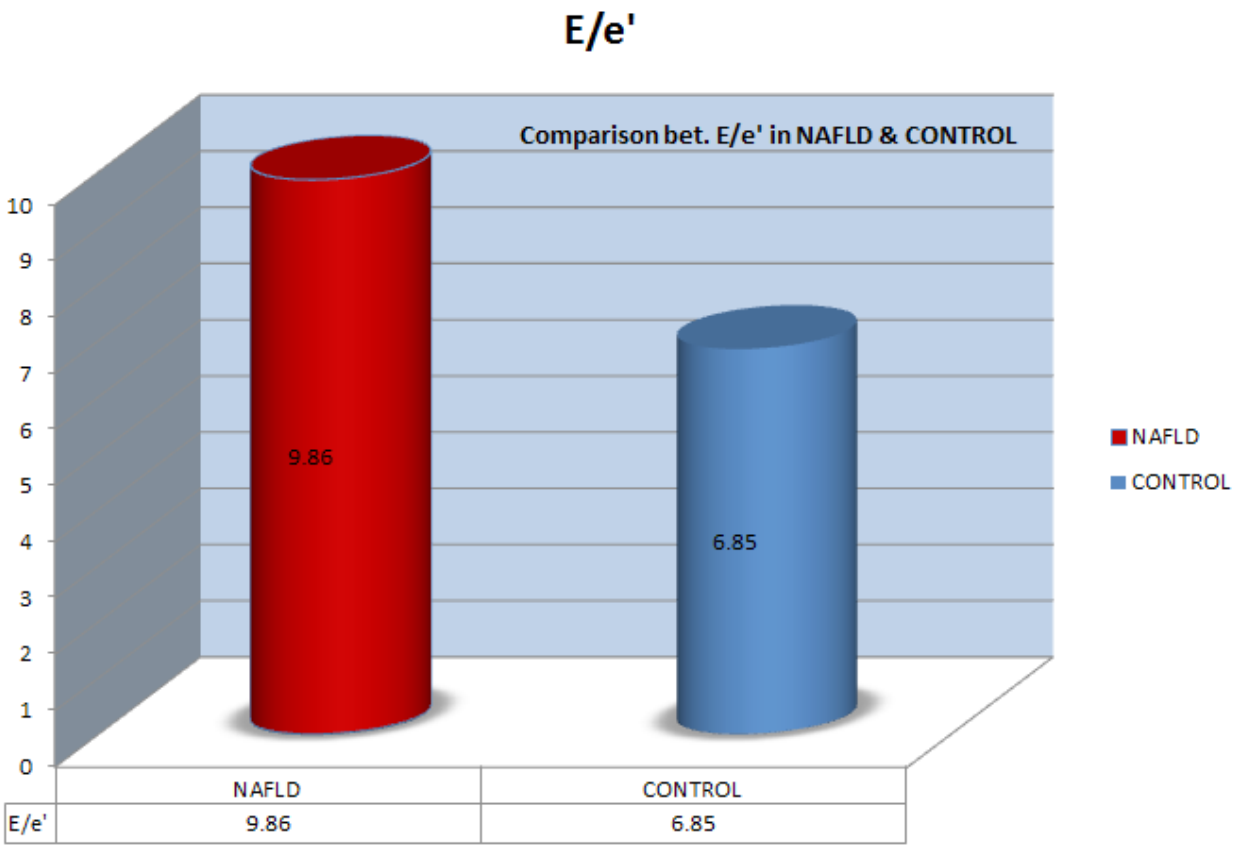

Figure 3. Comparison of E/e' between NAFLD and Control

Discussion

In this study, there is a significant difference in GLS between NAFLD patients and the control, although there is no significant difference LVEF between both groups. and this compatible with the study done by Zamirian M, Samiee E, Moaref A, Abtahi F, Tahamtan M. 2018[8]. GLS, an indicator of systolic function, in patients with NAFLD evaluated with those without NAFLD was reduced; showing superior subclinical systolic dysfunction in NAFLD patients. This result is similar to those stated by Singh et al. and VanWagner et al. in a decreased value of GLS in adolescents and adults with NAFLD(14). The presence of LV diastolic dysfunction, including higher E/e' ratio, lower S', and e' tissue velocity in patients with NAFLD has been mentioned in previous studies using TDI, (6). However, the comparison of LVEF between the two groups did not reveal any significant difference, illustrating that the use of this conventional tool would result in missing the early stages of LV systolic dysfunction[19]. Regarding diastolic dysfunction, there is a lower E and E/A ratio in NAFLD patients, furthermore, the Vp and e'weresignificantly lowerand the last most independent parameter associate with NAFLD on multivariate analysis, that a study had been done by Goland et al at 2006[6].Aboutbody lipid deposition, in NAFLD, anepicardial fat thickness, the high one is correlated with the liver fibrosis severity, with a probable pathogenic role keepingthe ectopic fat depots with body organ damage as a whole, when compared with control but still, these changes are statistically not significant and this goes with the study done by Petta S et al at 2015[20]. In NAFLD patients, the rise in free fatty acids may lead to lipid deposition on the myocardium, with the sequelaeof the alterations in the left ventricle (LV) performance[20][21][22].

Conclusion

The 2 D Speckle tracking echocardiography by assessing GLS is a sensitive method and more valuable than the ordinary 2D echocardiography in the early detectionof subclinical LV involvement in NAFLD patients. The patients with NAFLD were provedthat have significantly lower e' velocity and higher E/e' ratio in comparison with the individual that age and sex-matched who do not have NAFLD; suggesting the adverse effects of NAFLD on diastolic indices.

Levels of Some Biomarkers in Ischemic Heart Disease Patients

Majida Sulaiman Aadai [1], Mayada Noori Iqbal[2], Nahlah Ghanim Abdul Majeed[3]

[1]Student, [1]Department of immunology, AL Karama Teaching Hospital, Kut, Iraq, [2]Assist. Prof., College of Health and Medical Technology, Middle Technical University, Baghdad, [3]Department of Immunology, Teaching Laboratories, Baghdad Teaching Hospital, Baghdad, Iraq

Abstract

The present study is an attempt to investigate the changes in serum soluble suppression of tumorigenicity 2 (sST2) and Interleukin-33 (IL-33) biomarkers levels in Iraqi ischemic heart disease(IHD) patients including stable angina (SA), unstable angina (UA) and myocardial infarction (MI) compared to the healthy controls (HC), and to evaluate the differences in these levels between these diseases combination groups. The IHD'smortality surpass that of every major disease, so it is important that to get such research especially among Iraqi patients. These biomarkers are expressed by myocardial cells, the sST2 is released when there is a myocardial stress while the IL-33 has a cardio protective role, and both are expressed on atherosclerotic plaque which is the most common cause of IHD. Collecting the blood samples from one hundred thirty IHD patients with ages ranged (30-80) years, of both genders, excluding the patient with any autoimmune disease, investigated for sST2 and IL-33 by ELISA technique. This study revealed that the sST2 was highly significantly decreased in all IHD groups compared with HC; the 5% trimmed mean (ng/ml) was 8.48, 8.37, 9.31 versus 23.88 in SA, UA, MI and HC respectively; while the IL-33 was highly significantly decreased in SA and UA groups while not significantly different in MI patients;the 5% trimmed mean (ng/L) was 969.93, 762.21, 1279.45 versus 2110 in SA, UA, MI and HC respectively. Also there was a significant direct correlation between these biomarkers levels in all IHD groups.

Keywords: *sST2, IL-33, IHD, Stable angina, Unstable angina, Myocardial infarction.*

Introduction

The ischemic heart disease (IHD) is a disease of coronary arteries, so it is also called coronary heart disease (CHD) or coronary artery disease (CAD), in which there is a blood supply reduction to the myocardium, mostly due to atherosclerosis in the coronary arteries. It is the main cause of death worldwide, so it is important in many studies nowadays[(1)]. IHD can be classified into chronic stable angina (SA) and acute coronary syndrome (ACS) that include unstable angina (UA) and myocardial infarction (MI)[(2)]. The primary prevention of CAD is dependent upon the ability to identify high risk individuals[(3)]and by studying the novel biomarkerslong before the development of overt major adverse cardiac events (MACEs) [(4)]. The ST2 is known as interleukin-1 receptor-like-1 (IL1RL1) protein, it has two isoforms; ST2L and sST2, the later can act as a decoy receptor by binding freeIL-33,and it reflects the myocardial stress. It provides prognostic information especially in the MI[(5)]. The IL-33 is a cytokine,is a functional ligand for ST2L, is expressed by myocardial cells, it has a cardioprotective role and inhibits the atherosclerotic plaques development;it predicts the mortality andMACEs in the MI patients[(6)]. The present study aimed to investigate the changes in the serumsoluble suppression of tumorigenicity 2 (sST2) and Interleukin-33 (IL-33) biomarkers levels, as well as the risk factors such as age, gender, smoking and serum cholesterol level in Iraqi IHD patientswho are with SA, UA and MI compared to apparently healthy controls (HC) group.

Patients and Method

Collecting the blood samples from one hundred thirty patients with ages ranged (30-80) years, of both genders, newly admitted to different Iraqi hospitals(Ibn Al- Betar Teaching Hospital, Baghdad Teaching Hospital and The Iraqi Center for Heart Disease), classifying them into fifty patients with MI, fifty patients with SA and thirty patients with UA according to the clinical manifestations, electrocardiogram findings and laboratory investigations.

Patients with diabetes mellitus [confirmed by blood sugar and hemoglobin A1c levels (bychemistry autoanalyzer (AU480, Beckman))]and with any other autoimmune disease were excluded from this study[7]. Thirty five apparently HC were enrolled in this study with the same age range of both genders. A form of questionnaire was applied for both the patients and HC groups. This questionnaire listed some informations especially the age, gender,presence of the medical history (especially of any autoimmune disease) and whether smoker with its grading or not. Most of the patients serum samples were collected within about (24-48 hours) of the symptom onset and investigated for blood cholesterol level(by chemistry autoanalyzer (AU480, Beckman)), sST2 and IL-33 by enzyme linked immune sorbent assay (ELISA) technique [(sandwichkit) (Human)].

Statistical analyzing: Analysis of data was carried out by using the available statistical package of SPSS-22 . The significance of the differences of different means (quantitative data) was tested by using Mann – Whitney U test for the differences between two independent means, while Pearson's Correlation Coefficients was calculated for the correlation between two quantitative variables. The correlation coefficient value (r) was either positive (direct correlation) or negative (inverse correlation);in addition to the graphical presentation by using Stem-Leaf Plots and Receiver Operation Characteristic (ROC) curve charts.

Results

Table (1): Studied (sST2 and IL-33) biomarkers in all combinations of studied groups.

Biomarkers	Groups / Statistics	Stable Angina	Unstable Angina	Myocardial Infarction	Healthy Controls	Combinations Groups	Z-value	P value
sST2 (ng/ml)	5% Trimmed Mean	8.48	8.37	9.31	23.88	SA x UA	-0.666	0.505 NS
	Median	7.90	7.65	7.90	15.40	SA x MI	-0.179	0.858 NS
	Range (minimum-maximum)	(3.70-20.20)	(2.10-26.00)	(2.40-46.20)	(6.40-53.90)	SA x HC	-5.316	0.000HS
	Interquartile Range	2.63	4.30	1.63	30.10	UA x MI	-0.726	0.468 NS
						UA x HC	-4.567	0.000HS
						MI x HC	-5.021	0.000HS
IL-33 (ng/L)	5% Trimmed Mean	969.93	762.21	1279.45	2110	SA x UA	-0.925	0.355 NS
	Median	756.40	756.45	912.40	1340.9	SA x MI	-3.864	0.000HS

Data presented as 5% Trimmed Mean, median, Interquartile Range and P value tested by Mann-Whitney U Test.SA: Stable angina;UA: Unstable angina; MI: Myocardial infarction; HC: Healthy controls; HS: Highly significant at P value <0.01;S: Significant at P value <0.05;NS: Non significant at P value >0.05; sST2: soluble suppression of tumorigenicity 2;IL-33: Interleukin-33.

In the table (1), the results of the sST2 and IL-33 biomarkers test had reported low levels of estimates compared with HC group. The 5% trimmed mean (ng/ml) concerning the sST2 was 8.48, 8.37, 9.31 versus 23.88 in SA, UA, MI and HC respectively; the IL-33 was highly significantly decreased in SA and UA groups while not significantly different in MI patients; the 5% trimmed mean (ng/L) concerning the IL-33 was 969.93, 762.21, 1279.45 versus 2110 in SA, UA, MI and HC respectively. Also this table shows that Mann-Whitney-U test statistic for testing distribution of sST2 and IL-33 biomarker's readings in each pair of probable combinations among studied groups. Regarding to sST2

biomarker, the significant differences are accounted at P <0.01 among the morbidity groups against the HC, while no significant differences at P >0.05 among diseases combinations groups such as between SA group and each UA and MI groups, and between UA and MI groups. Regarding to IL-33 biomarker, the significant differences are accounted at P <0.05, except between SA and UA groups, and between MI and HC groups, since no significant differences at P >0.05.

Table (2): Statistics of ROC Curve for studied (sST2 and IL-33) biomarkers responding according to (diseases and healthy) groups.

Groups	Biomarkers	Cutoff Point	Sensitivity	Specificity	Area	Standard Error	A. S.	Asymptotic 95% C. I.	
								L. b.	U. b.
Stable Angina	sST2 (ng/ml)	3.850	0.960	0.000	0.160	0.046	0.000 HS	0.070	0.250
	IL-33 (ng/L)	588.25	0.880	0.171	0.321	0.065	0.005 HS	0.194	0.448
Unstable Angina	sST2 (ng/ml)	2.250	0.967	0.000	0.170	0.049	0.000 HS	0.073	0.266
	IL33 (ng/L)	188.35	0.967	0.000	0.252	0.060	0.001 HS	0.134	0.370
Myocardial Infarction	sST2 (ng/ml)	4.350	0.960	0.000	0.179	0.052	0.000 HS	0.077	0.281
	IL33 (ng/L)	730.75	0.960	0.314	0.457	0.073	0.503 NS	0.315	0.599

HS: Highly significant at P value <0.01; NS: Non significant at P value >0.05; A. S.: Asymptotic significant;C. I.: Confidence interval; U. b.: Upper bound; L. b.: Lower bound; sST2: soluble suppression of tumorigenicity 2; IL-33: Interleukin-33. The positive actual state is Positive.

In the table (2), the results recorded significant area by Receiver Operation Characteristic (ROC) curve under the guideline of HC group in all IHD groups, with 95% confidence interval (C. I.) of all diseases with HC groups in light of studied sST2 and IL-33 biomarkers. In both SA and UA patients, the results show that the recorded significant area at P <0.01 concerning both biomarkers, with more accurate concerning sST2 compared with the IL-33, and accordingly indicating that both biomarkers could be reported good indicators for SA and UA diagnosis; while in MI patients, the results show that the recorded significant area at P <0.01 concerning sST2 biomarker, and accordingly indicating that the sST2 biomarkercould be reported very good indicator for patient's diagnosis with MI, while IL-33 biomarker illustrated weak or non-reliable indicator for MI diagnosis, since significant level was not achieved.

Figures (1,2 and 3) show that the ROC curve distribution concerning the sST2 and IL-33 biomarkers responding according to compare SA, UA and MI patients under the guideline of HC group respectively.

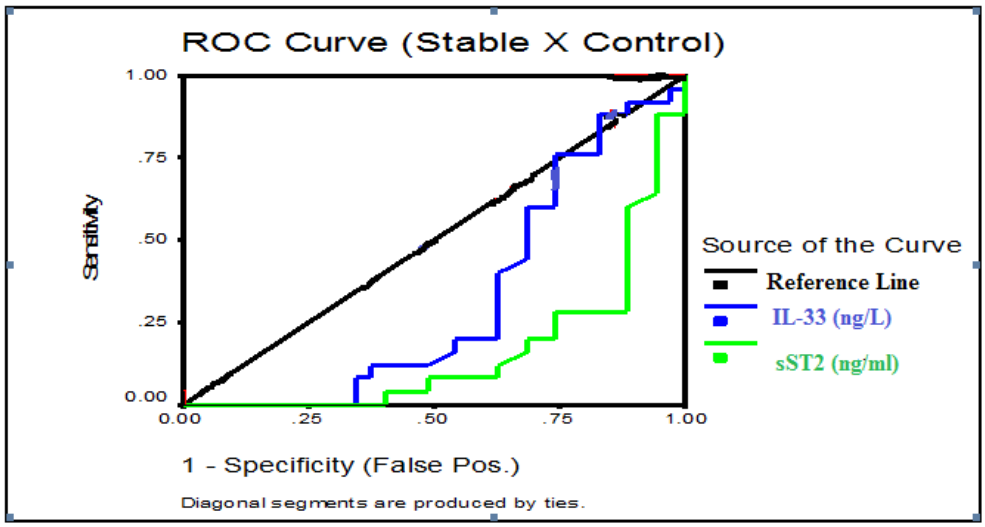

Figure (1): ROC Curve distribution for studied (sST2 and IL-33) biomarkers distributed according to (stable and healthy) groups. IL-33: Interleukin-33; sST2: soluble suppression of tumorigenicity 2.

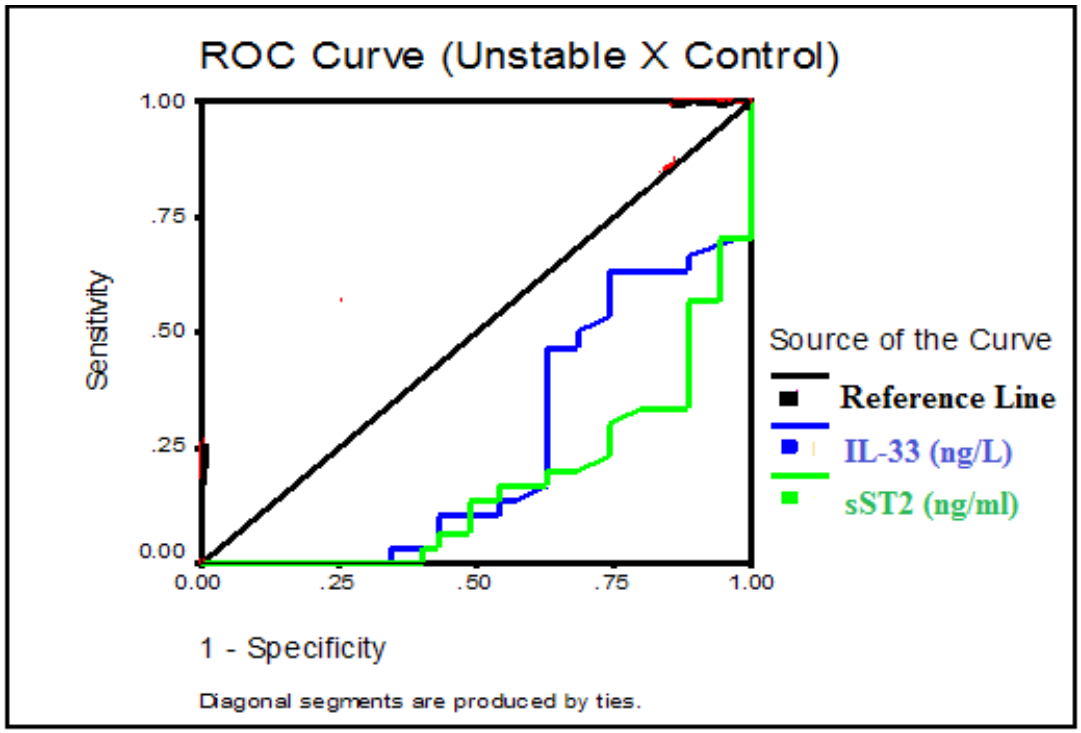

Figure (2): ROC Curve distribution for studied (sST2 and IL-33) biomarkers distributed according to (unstable and healthy) groups.IL-33: Interleukin-33; sST2: soluble suppression of tumorigenicity 2.

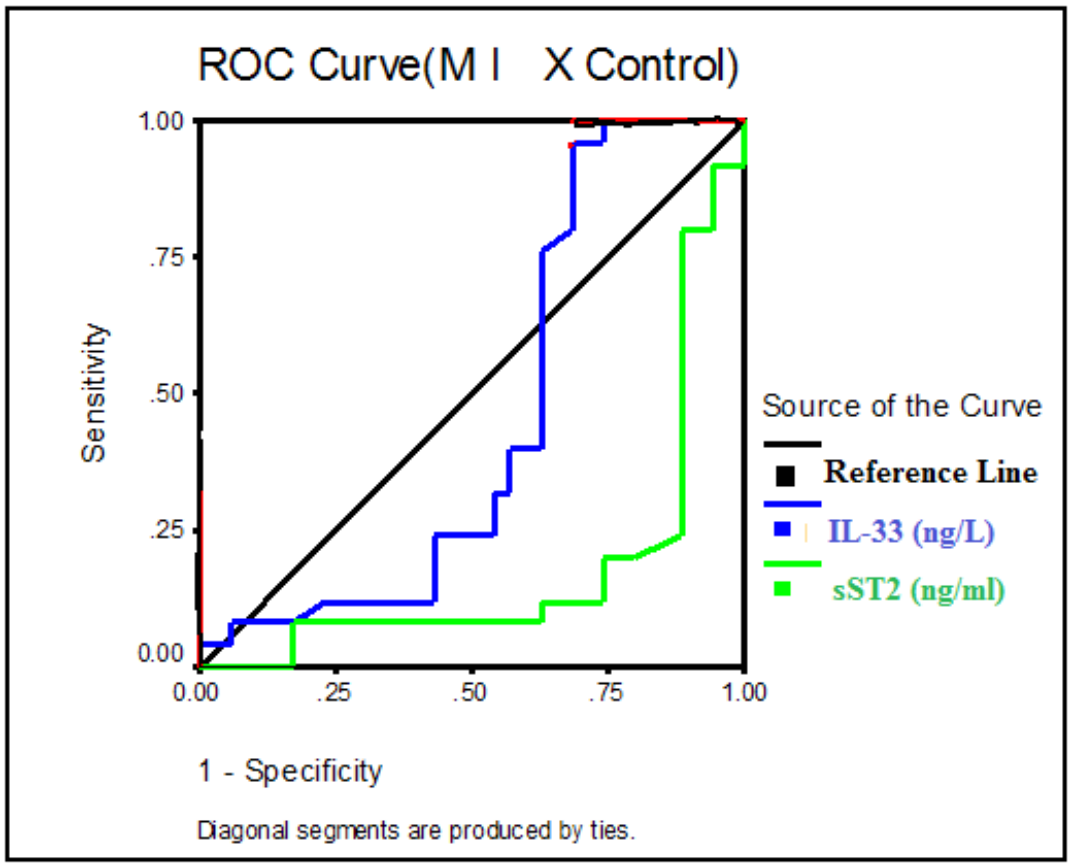

Figure (3): ROC Curve distribution for studied (sST2 and IL-33) biomarkers distributed according to (myocardial infarction and healthy) groups. IL-33: Interleukin-33; MI: Myocardial infarction;sST2: soluble suppression of tumorigenicity 2.

Table (3) shows that there is a perfect positive correlation and a direct proportion between the sST2 and IL-33 biomarkers levels in all disease groups by using Person's Correlations Coefficients, with highly significant at P <0.01.

Table (3): Using Person's Correlations Coefficientsfor (sST2 and IL-33) biomarkers responding according to stable angina, unstable angina and myocardial infarction groups.

Morbidity Groups	Marker (ng/ml)	Statistics	IL33 (ng/L)
Stable Angina	sST2	Correlation Coefficient	0.862
		Significant (1-tailed)	0.000HS
		No.	50
Unstable Angina	sST2	Correlation Coefficient	0.469
		Significant (1-tailed)	0.004HS
		No.	30
Myocardial Infarction	sST2	Correlation Coefficient	0.505
		Significant (1-tailed)	0.000 HS
		No.	50

HS: Highly significant at P value <0.01; No.: Number; sST2: soluble suppression of tumorigenicity 2; IL-33: Interleukin-33.

Discussion

The atherosclerosis formation tends to increase with age[8] and most of the IHD cases occur after the age of 65 years[9]. The male gender is one of the risk factors for IHD[10], so the present study results were compatible with the results of many studies regarding to the age and gender[11, 12].

Tobacco smoking is the most avoidable and strongest IHD risk factor [13]. It causes the death in IHD cases[14], the present study smoking results are exactly compatible with Radovanovic *et al*[8] and agree with Mohammad *et al*[15] studies results. Blood cholesterol is a predictive risk factors for CAD[16], and it play a role in the atherosclerosis development[17], so the present study cholesterol test results are agree with Chauhan and Trivedi[13], and Oommen*et al*[18] studies results.

The ST2 is released when myocytes are under stress or injuried [19], it plays a role in inflammatory signaling[20], cardiac fibrosis [21], and is involved in cardiac function and dysfunction [22]. In the extra cellular environment, the sST2 can act as a decoy receptor by binding free IL-33 [6].

The IL-33 is a functional ligand for ST2L, is expressed by myocardial cells, it has a cardioprotective role and inhibits the atherosclerotic plaques development[23]. IL-33 is expressed by myocardial and coronary arterial smooth muscle cells[24]. Both IL-33 and sST2 are expressed in atherosclerotic plaques, when sST2 is binding the free IL-33, the IL-33 level that is available for ST2L binding will be decreased, inhibiting the effects of IL-33/ST2L signaling which has a myocardioprotective function[25]. This IL-33/ ST2L signaling may be triggered by IL-33 or increased by inhibiting sST2 [26], so by the measurement of sST2 level, we can understand the role of IL-33 in IHD [27], so it is very important to study them together. Some results suggest that the ST2 concentrations may be elevated in some MI patients [28,29], while some studies revealed that its level may be not elevated in the MI patients [30]. It was found that the IL-33 levels were not different between the patients with the MI and the control group [31], while other study showed that the patients with heart failure with non-ischemic etiology had higher IL-33 levels than those with ischemic etiology [32]. The presence of the IHD risk factorssuch as age, gender or smokingdoes not influence the serum levels of both sST2 [31,33] and IL-33 biomarkers [27].

Regarding to the sST2 biomarker level, this study recorded that there was some elevation of sST2 level in the HC group in comparison with the lower levels in the morbidity groups; in the HC group, the minimum level was (6.4 ng/ml) and the maximum level was (53.9 ng/ml),

while the minimum level in the morbidity groups was in the UA group (2.1 ng/ml) and the maximum level was in the MI group (46.2 ng/ml). Some studiesrecorded that there were low levels of sST2 (6.2 ng/ml) in MI[30, 34,35]. The sST2 is also elevated in the asthma and autoimmune disease[7]; it reflects a non-specific inflammatory response thus limits its specificity and diagnosis for any disorder including IHD[5, 36]. The sST2 peak level occurred at 12 hours[37](6-18 hours of symptom onset) then is followed by a significant decreasing to a stable level by (24-42 hours) after the onset[21, 33].

Early post infarction sST2 values (i.e., < 24 hours after symptom onset) have the greatest significant prognosis [33], as it has been found that the baseline sST2 levels were significantly higher (the cutoff value of 58.7 ng/mL) in those patients who died or developed new MACEs such as heart failure or recurrent MI either in MI, in stable IHD or even in subjects without known IHD, during short-term follow-up (30 days) than those patients without MACEs[7,21,29,31,35]. Sothe importance of early sST2 levels is for the best prognostic information[33], so that we can prevent morbidity and mortality of the IHD by providing rapid and appropriate therapy[37]. in addition to that the most of Iraqi patients are too late to come to the hospital or physician after the beginning of symptom onset, the Iraqi patient may come after 24 hours of his first complain, so the sST2 peak level could not be detected in such situation as we knew that the peak level is 12 hours after the symptom onset.

In comparison with HC group, one of the studies stated that the ST2 baseline level had a clinical significant in SA patients[33] and it was reported that there was a significant difference in both UA and MI patients[31]. In diseases combination groups, it was showed that there was no significant difference between SA and MI groups, and confirmed that the sST2 has no significant distribution value for combination of UA and MI groups[34]. The study of Karimzadeh *et al* [38] observed that there was a significant correlation between the serum sST2 and IL-33 biomarkers levels in all the IHD.

In diseases combination groups, concerning to IL-33, it was showed that there was no significant difference between SA and UA groups [31, 35]; some studies showed that there was a significant difference between SA and MI groups and suggested that in SA patients, the IL-33 has a protective role against progression to UA or MI stage[41], while it was demonstrated that there was a significant difference between UA and MI groups regarding to IL-33[27].

Brain Hydatidosis Surgical Outcome

Mohammed Z. Shaker[1], Nashwan Y. Sallama[1], Mohammed I. Ramadhan[1]

[1]*Neurosurgeon, Department of Neurosurgery, Ibn-sina Teaching Hospital, Mosul, Iraq*

Abstract

Background: Brain Hydatidosis is one of common parasitic brain diseases accounted in Iraq. This is prospective study done in mosul teaching hospital in Iraq during 2007-2020.

Material and Method: All patient data had collected from the records of 19 patients admitted to Mosul center with hydatidosis, including clinical features and imaging investigation in addition to operative record .Follow up of all included patient was achieved.

Results: Ninteen patients were included, twelve male and seven female . Eighteen patients were of intracerebral hydatidosis while one was extradural. Eight patients in parietal lobe, five patients in frontoprietal lobe,,three patients in occipital lobe, two in cerebellum and one patient in frontal. Age ranged 3-45 years where sixteen patients were children. Three patients get multiple cysts while the other sixteen get solitary hydatid cyst. All patients were treated by craniotomy and total excision (delivery) of hydatid cyste(s) while rupture occurred on one case and albendazole had given for all of patients postoperativly. All patients except two get retune to normal neurological function while one still in deficit the other one died due to postoperative infection. No recurrence was seen.

Conclusion: Brain hydatidosis is still seen in our country and early surgery provide good treatment in addition to use of albendazole while mortality and morbidity are not uncommon postoperative events.

Keywords: *Hydatid cyst, Brain infestations, Iraq.*

Introduction

hydatid disease is a chronic zoonotichelminthic infection caused by larval stage of the dog tapeworm called *Echinococcus granulosus*. Hydatidosis is endemic throughout Middle East[1,2]. This disease is usual in areas that cattle, sheep, and dogs arekept. Liver and lungs are common involvedorgans but in other organs of body such asbones, brain and heart may be found[3,4,5]. Human infestation may take one of the three forms:unilocular hydatid disease caused by *Echinococcus granulosus*, multilocularor alveolar disease caused by *Echinococcus multilocularis* and polycystic hydatid disease caused by *Echinococcus vogeli* . Members of the dog family are definitive hosts for these minute tapeworms. Eggs are passed in the stools and ingested by the intermediate hosts, which include sheep, cattle, pigs, rodents and other herbivorous animals. Humans,especially children are infected. Following the accidental ingestion of eggs from environment, the eggs hatch in the intestine and the embryo penetrate the intestinal wall and then enter the blood stream. Although most hydatids develop in the liver, some disseminated to other sites. These may even reach the brain [6]. Larval stage of the cesto can involve the brain via the choroid plexus.[7] Cerebral hydatid cyst are usually localised within the watershed zone of the middle cerebral arteries, often in the parietal lobe.[8,9] Cerebral hydatid cysts are usually single, spherical and unilocular[10,11]

Its incidence is 1–2% of all cases with hydatid disease. Brain hydatidosis is an important differential diagnosis of intracranial cystic lesions in endemic regions, for example, the Middle-Eastern countries.

Subjects and Method

Study method include that retrospectively reviewing the clinical features (neurological symptoms and signs), radiological manifestations (X-ray, computerized tomography (CT) scan or magnetic resonance imaging (MRI)) and surgical outcome of 19

patients with intracranial hydatid cysts whom received surgicaltreatment at the Neurosurgical Department of Ibn Sina hospital from January 2007 to January 2020. The patients records were retrospectively reviewed all the clinical, radiological data of all patients who were diagnosed as harboring an intracranial hydatid cyst during the period of study and subsequently underwent surgery at the Department of Neurosurgery, Ibn Sina hospital. Follow up of patients was done by clinical and radiological evaluation for a minimum period of 6 months up to 2 years .

Surgical therapy was adopted for all patients and Craniatomy with big osteoplastic flap and use of Dowling-Orlando's technique for delivery of hydatid cyst was the only type of surgery for all patients. Medical thereapy: albendazol as chemotherapy for 28 days had been standard way of medical treatment after surgery.

Results

The current study has included nineteen patients of them twelve male (63-%) and seven female (37%) .

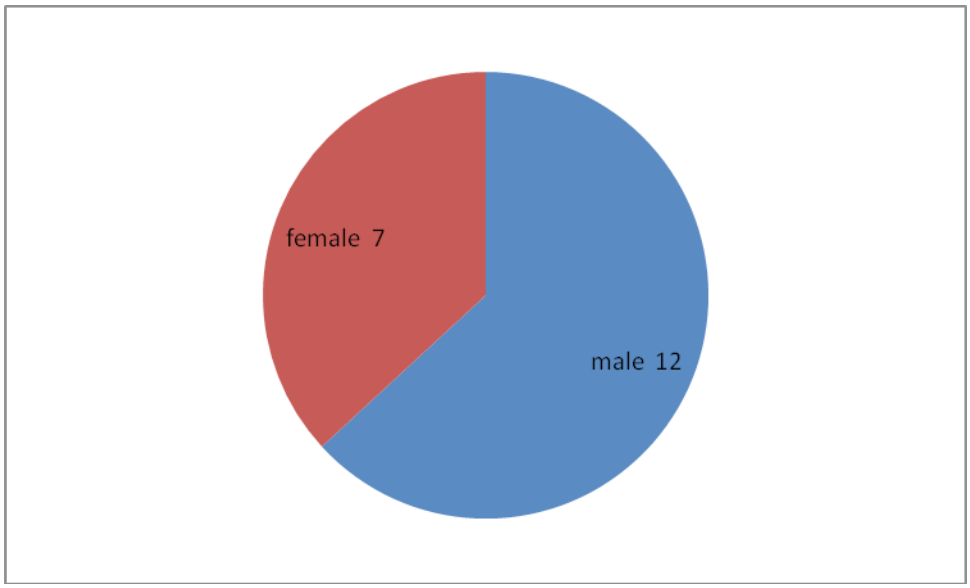

Figure (1): Sex distribution

The age distribution was 16 patients in childhood age (below 18 years) and three were adults.

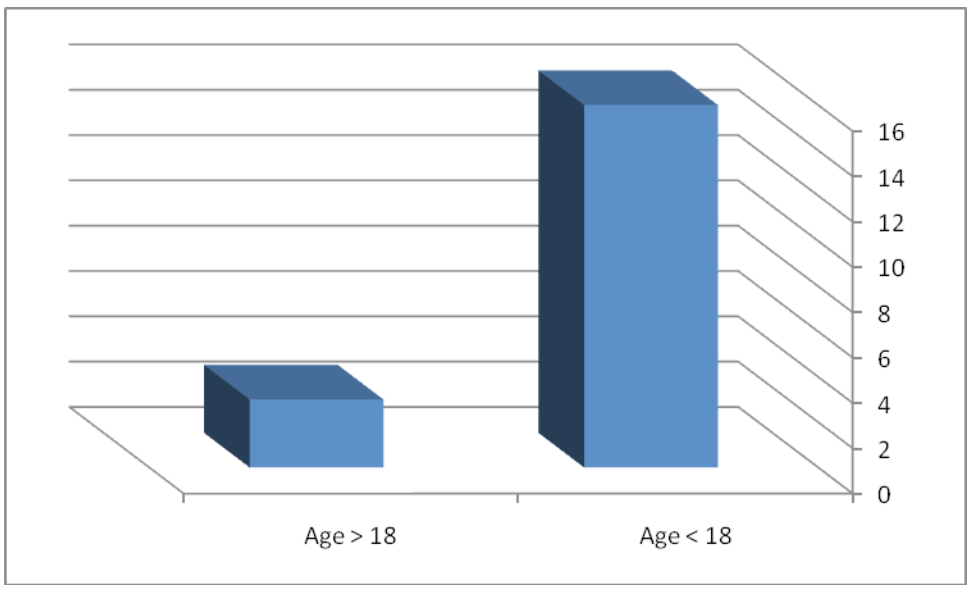

Figure (2): Age distribution

All patients in this study were from rural area except one,two adult patients were from one family. The clinical features at time of patients presentation was headache in 17 of cases, seizure in 4 cases, motor weakness in 17 cases, vomiting in 4 cases and altered level of consciousness in 5 cases. Behavior changes were in one patient .

While the clinical signs revealed papilledema in 12 cases, sixth cranial nerve pulsy in 3 cases .

Table 1: Clinical presentation distributions

	Number of cases
Headache	17
Vomitting	4
Seizure	4
Motor weakness	17
Disturbe level of consciousness	5
Behavior changes	1
Papilledema	12
Sixth nerve pulsy	3

All patients had investigated by CT and MRI, with three patient harbor multiple cyst while the others diagnosed as single cerebral hydatidosis.

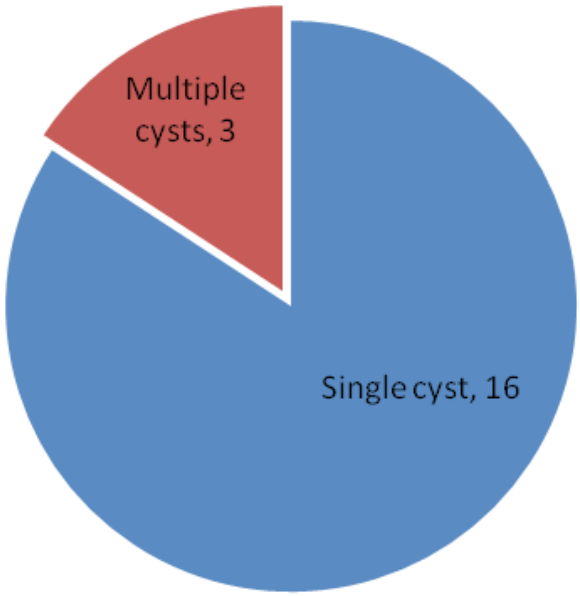

Figure (3): Multiplicity of cyst distribution

The anatomical distribution of cysts were eight patients in parietal lobe, five patients in frontoprietal lobe,,three patients in occipital lobe, two in cerebellum and one patient in frontal.

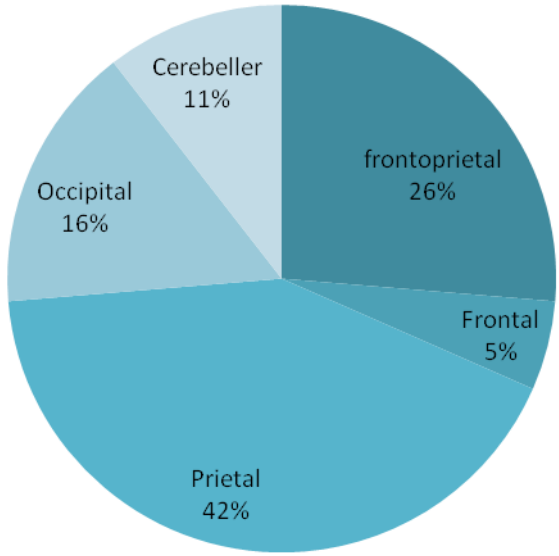

Figure (4): Anatomical location distributions

All patients were underwent craniatomy within 24-48 hours after establishment of diagnosis and successfully intact delivery of cyst(s) achieved in eighteen patients while rupture of multiple extradural cysts had occur .

All patients were kept in hospital 5-14 days and then discharge home.

Discussion

Echinococcosis (hydatid disease or hydatidosis), caused by the cestode Echinococcus granulosus is a widespread zoonotic illness and can involve brain in rare cases, They account for 1% to 5% of all intracranial masses in endemic areas[12, 13]The natural history of the cerebral hydatidosis is usually slow and presents late when they reach relatively large volume. There is no consensus on the growth rate of the hydatid cysts of the brain and has been variably reported between 1.5-10 cm/ year[14]

The dominance paediatric involvement by hyadatid cyst had proved in this series with the 86% of incidence who were less than 15 years age that stay one of the most agreed point in most of the published seriesas inIzci *et al* who reported a series of 17 patients with intracranial hydatid cysts and 13 (65%) of these patients were children adopting the patent ductus arteriosus or the direct contact with dogs or eating contaminated food and milk.[15, 16,17]

We founded in this study that pediatric cerebral hydatid disease involves all intracranial parts while cerebellum was immune in adult patients.Although

the paediatric predominance the male gender was predominant in paediatric group (3:1) while the reverse in adult group where female appeared to be more involved (2:1) . The cerebral hydatid cyst can be single (primary) or multiple (secondary) . In this series there were two multiple cysts cases in paediatric group and only one in adult, while all the crebeller hydatid cases were of single type.

In the view of intracranial compartment distribution the supratentorial distributon of cysts were observed in all cases except two, with high prevelance for parietal lobe as it involved in 12 patients (80 %) the same observation were reportedfor all four cases reported by Dharker et al [18] and three out of five cases of intracerebral hydatid cysts reported by Balasubramaniam et al[19] had parietal lobe involvement which reflect the distribution of middle cerebral artery supplement.

As any slowly growin brain space occupying mass the common presentations of patients in this series were symptoms and signs of raise intracranial pressure and/ or pressure effect. The vast majority were present with headache (90 %) and founded to get papilloedema in 12 patients (63%) which can be explained by the large size of the cyst as there was no hydrocephalus in all patients. The same proved by by Erashin et al[20] who observed that 18 out of 19 cases presented with raised intracranial pressure symptoms and signs,As the common site of cerebral hydatidosis was parietal, frontal and frontoprietal region (73 %) in this series the common local pressure feature was motor weakness observed in 90% of patients.

The adoptive surgical procedure (Dowling-Orlando's technique) had proved to yield high success rate in the delivery of intact brain hydatid cyst which achieved in 95 % of cases and hence the recurrence rate was very low compared with relatively significant recurrence in ruptured hydatid surgically treated by other procedures who showed 0.3–53%[21] while other writer had founded almost recurrence of all rupture cases as in El-Shamam et al. [22]

The adaptation of Dowling-Orlando's technique in this series with low rupture rate led to the absence of serious complication. Even the ruptured cysts had occurred in extradural case with good recovery. The potential for effective treatment is greater with intradural cysts, since they are often single and have thicker walls; then intact removal is more likely. measures should be adopted to reduce the likelihood of intraoperative rupture because it is not only associated with the recurrence of the lesion, but also causes various types of allergic reactions and even anaphylactic shock[23]

There were no difference in the delivery of intracerebral single or multiple cysts as rupture occurred in the extradural cysts only which may attributed to more adherernce between dura and cysts. The only one patient died after operation by two weeks from infection had occurred in 6 years age child harboring cerebellar single cyst,Most of all cases harbored giant cyste(s) with extension to the cortex and this made delivery of cyst more easy with less neural tissue injury.Adopting albindazol therapy for all patients after operation in doses for patients weighing more than 60 kg in a dose of 400 mg twice daily for 28 days. A dose of 15 mg/kg of body weight daily in 2 divided doses (not to exceed total daily dose of 800 mg) has been suggested for patients weighing less than 60 kg. There were no significant side effects observed from use of this drug among our patients

Conclusions

The hydatid cyst still not uncommon in the middle east countries and should not be under estimated,Early diagnosis at time being is feasible in the availability of imaging techniques and the unique feature of cyst. Adopting Dowling-Orlando's technique in the surgical management of brain hydatidosis proved to yield excellent results with low mortality and morbidity rate. We advise for Albindazole therapy for 28 days after surgery.

Abstract

Case control study was carried out in Salah-Addin city in private ophthalmology clinic from 1st November of 2019 to End february 2020. The study included 90 individuals including sixty diabetic patients (30 who had retinopathy and 30 without retinopathy) and 30 healthy individuals to evaluate the level of Malondialdehyde (MDA) in diabetic patients with and without retinopathy and healthy controls. All patients were aged between (51-82) years, with a negative history of antioxidant supplementation consumption. Blood samples were collected from each patients and controls to evaluate the levels of malondialdehyde and HbA1c by using immunofluorescence technique. The study showed that majority of diabetic retinopathy (DR) patients were females and the highest mean of age was recorded in diabetic retinopathy patients (60.76±7.25 year) compared with diabetic without retinopathy patients (58.31±9.19 year). The study displayed that the highest mean of MDA was recorded in DR patients as compared with diabetic without retinopathy patients (390.37±108.68 *vs* 336.97±94.95 ng/ml), although the result was non-significant (P: > 0.05). The study showed that the highest mean of MDA was in DR patients (390.37±108.68 ng/ml) followed by diabetic without retinopathy patients (336.97±94.95 ng/ml) and the lowest mean was in healthy individuals (293.32±42.51 ng/ml), (P: < 0.05). The study showed that, HbA1c was elevated significantly (P<0.05) in diabetic retinopathy patients (9.26±1.54) compared with diabetic without retinopathy patients (7.84±1.02). The present study displayed that the highest mean of duration of DM was recorded in diabetic retinopathy patients (13.48±6.00) compared with Diabetic without retinopathy patients (6.34±2.78), the result was significant (P:<0.05). The study showed negative correlation between HbA1c and BMI in DR patients; and no correlation between HbA1c and BMI in DM patients without retinopathy, The study showed negative correlation between MDA and HbA1c in DR patients and no correlation in DM patients without retinopathy.

Conclusion: Long duration of DM and the old age were risk factors for DR, poor control of was more disposed to develop retinopathy and oxidative stress is still higher in diabetic patients with retinopathy than patients without retinopathy.

Keywords: *Malondialdehyde; Diabetic retinopathy; Oxidative stress; HbA1c.*

Introduction

Diabetes mellitus (DM) is expected to affect around 550 million people all over the world according to global estimates of the prevalence of diabetes[(1)]. DM is characterized by constant hyperglycemia that damages various organs and manifests in macro vascular complications like premature atherosclerosis resulting in strokes, peripheral vascular disease, and myocardial infarctions and micro vascular complications such as nephropathy, neuropathy, and retinopathy[(2)]. Diabetic retinopathy (DR) is the number one cause of blindness in people between 27 and 75 years of age. Prevalence of DR is around 25% and 90% at 5 and 20 years, respectively, from diagnosis; it is calculated that 191 million people will be diagnosed with this micro-vascular complication by the year 2030[(3)]. Through the last three decades, extensive scientific reports have shown ROS to play an important role in DM complications such as diabetic neuropathy,

nephropathy, and retinopathy due to alterations on the biomechanisms involved in the instauration and progression of micro-vascular complications[4]. These three micro-vascular complications share high glucose levels as a starting point; such condition is necessary, but may not be enough to initiate the damage present in the peripheral nervous system (neuropathy), kidneys (nephropathy), and retinas (retinopathy) of diabetic patients[5,6]. Hyperglycemic states favor the activation of alternative pathways leading to reactive oxygen species (ROS) formation and augmented concentrations locally and in the rest of the body even at the point of surpassing the antioxidant capacity, a state known as oxidative stress affecting retinal integrity[7,8]. The study aim of this work was to evaluate the level of Malondialdehyde (MDA) in diabetic patients with and without retinopathy and healthy controls.

Patients and Method

Case control study was carried out in Salah-Addin city, a private ophthalmology clinic from 1st November of 2019 to End february 2020. The study included 90 individuals including sixty diabetic patients (30 who had retinopathy and 30 without retinopathy) and 30 healthy individuals. The information about patients in this study was retrieved from patient's itself. The diabetic patients (with and without) retinopathy were diagnosed by analysis RBS and HbA1c and fundoscopical examination by the ophthalmologist. All patients were aged between (51-82) years, with a negative history of antioxidant supplementation consumption, and their weight were (64–120)kg, with BMI range (19.56 - 49.94) . The criteria of exclusion include non-diabetic and malignant disease . The results of the patients groups were compared with healthy individuals nearly comparable age and BMI. About five milliliters of blood were collected from the antecubital vein of patients and controls in plain tubes without any anticoagulant at room temperature for 10-15 minutes and allowed to clot. The tube then were centrifuged (3000 rpm) for 15min. The clear serum was pipetted into clear dry Eppendorf's and stored at (-20^{o}C) until used for the various investigations. The levels of malondialdehyde, HbA1c were measured by using immunofluorescence technique.

Results

The study displayed that the highest mean of MDA was recorded in DR patients as compared with Diabetic without retinopathy patients (390.37±108.68 *vs* 336.97±94.95 ng/ml), although the result was non-significant (P: > 0.05). as shown in the Table 1.

Table 1: Level of MDA in diabetic patients (with and without retinopathy).

MDA(ng/ml)					
Group	**Mean**	**SD**	**Max**	**Min**	**P value**
Diabetic retinopathy	390.37	108.68	548.56	197.76	NS
Diabetic without retinopathy	336.97	94.95	113.36	94.95	

In the current study a significant difference between DR patients and healthy individuals regarding mean of MDA (390.37±108.68 *vs* 293.32±42.51 ng/ml), (P: < 0.05), as shown in the Table 2.

Table 2: Level of MDA in DR patients and healthy individuals.

MDA(ng/ml)					
Group	**Mean**	**SD**	**Max**	**Min**	**P value**
Diabetic retinopathy	390.37	108.68	548.56	197.76	< 0.05
Healthy individuals	293.32	42.51	386.56	211.76	

The study showed that the highest mean of MDA was recorded in diabetic without retinopathy patients (336.97±94.95 ng/ml) as compared with healthy individuals (293.32±42.51 ng/ml), the result was significant (P: <0.05). Figure 1.

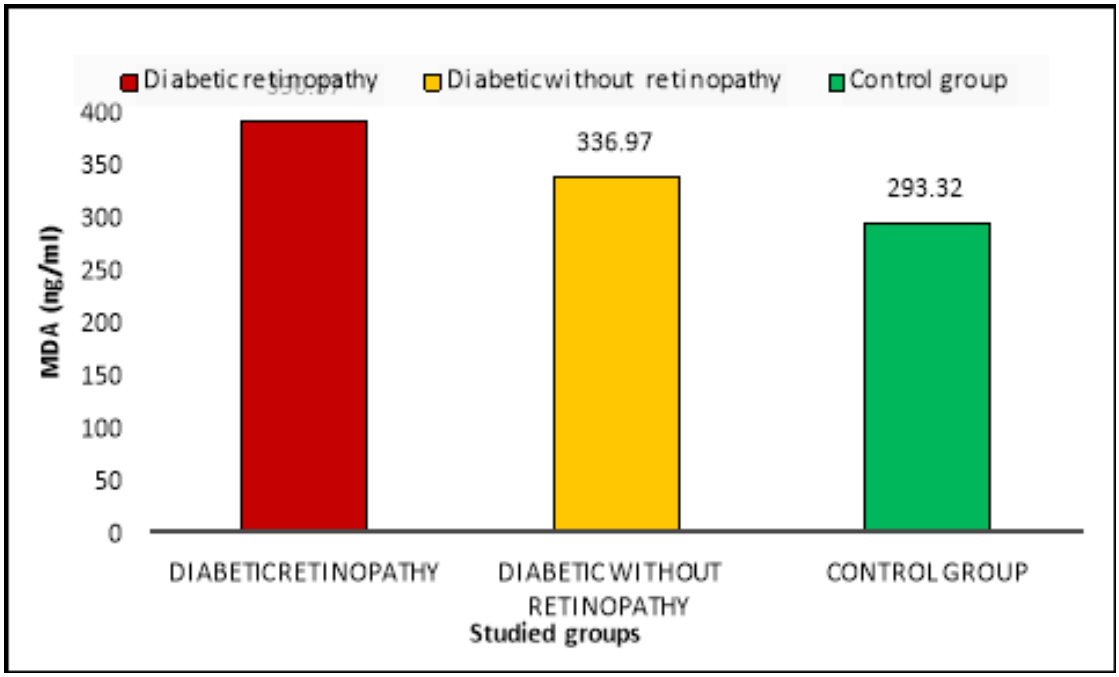

Figure 1: Mean of malondialdehyde (MDA) in the studied groups

The study showed that, HbA1c was elevated significantly (P<0.05) in diabetic retinopathy patients (9.26±1.54) compared with diabetic without retinopathy patients (7.84±1.02), as shown in the Figure 2.

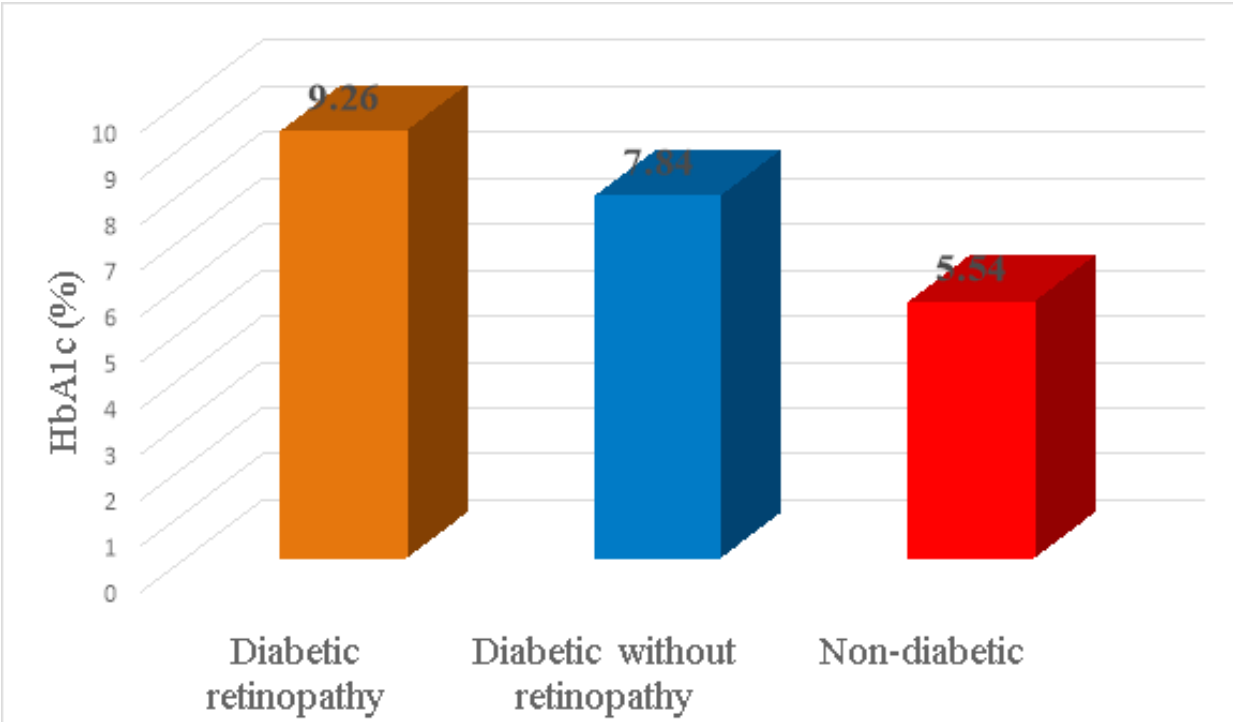

Figure 2: Means of HbA1c levels in the studied groups

The present study displayed that the highest mean of duration of DM was recorded in diabetic retinopathy patients (13.48±6.00) compared with Diabetic without retinopathy patients (6.34±2.78), the result was significant (P:<0.05). As shown in the Table 3.

Table 3: Mean of duration of DM in diabetic retinopathy patients and Diabetic without retinopathy patients.

Duration of DM (year)					
Group	**Mean**	**SD**	**Max**	**Min**	**P value**
Diabetic retinopathy	13.48	6.00	30.00	5.00	< 0.05
Diabetic without retinopathy	6.34	2.78	10.00	0.80	

The study showed negative correlation between HbA1c and BMI in DR patients (r: - 0.21) and no correlation between HbA1c and BMI in DM patients without retinopathy (r: -0.04), Figure 4 (A & B).

The study showed negative correlation between MDA and HbA1c in DR patients and no correlation in DM patients without retinopathy (r: -0.35 and 0.04 respectively), Figure 4(B & C).

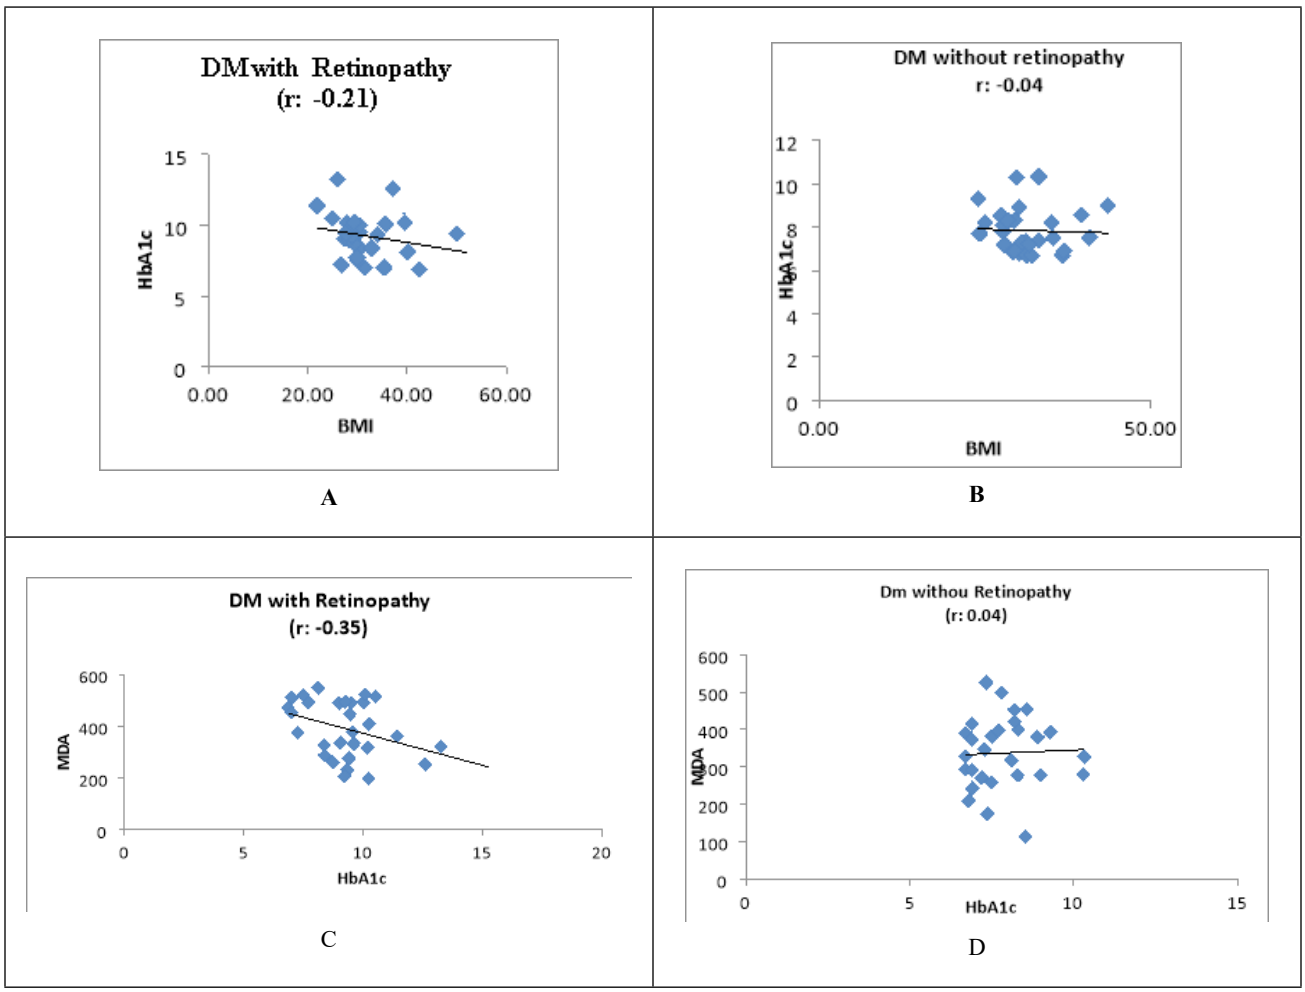

Figure 4: Correlation between A- HbA1c and BMI in DR patients;B- HbA1c and BMI in DM patient without retinopathy;C- MDA and HbA1c in DR patients;D- MDA and HbA1c in DM patients without DR

Discussion

The study showed that majority of diabetic retinopathy (DR) patients were females (23 of 29 (79.31%)) compared by 17 (58.62%) females of DM group without retinopathy and 14(48.28%) of healthy individuals were females.

The study showed that the highest mean of age was recorded in diabetic retinopathy patients compared with

diabetic without retinopathy patients although the result was non-significant (P: > 0.05). The highest mean of age was recorded in diabetic retinopathy patients compared with healthy individuals, the result was significant (P<0.05). The study revealed that the highest mean of age was recorded in diabetic without retinopathy patients as compared with healthy individuals, although the result was non-significant (P: > 0.05).

This finding agree with study done by Rajab[9] . The mean age was 50 years old ranging from 25-67 years, with 65% between the ages of 50-65 years old and the standard deviation was (± 10.95) and the retinopathy rate was highest in the age group 50-59 years (37%). Also, Abebe *et al* [10] reported that Diabetic patients aged ≥65 years are less likely to have poor glycemic control compared to other age groups similar to another study done here in Gondar and in USA, which indicated that elderly people had better diabetes control. The retinopathies rate increased with age until the age of 70 years; however, the small number of people with diabetes in this age group limits our ability to interpret the finding. Some studies reported a significant association between DR and age. Aging, high blood glucose and high blood pressure cause microvascular destruction of blood vessels which increase with time of exposure so aging and duration of diabetes is main risk factors of diabetic retinopathy [11,12].

On the other hand the current study disagree with study done by Goyal *et al* [13] showed the mean age of patients with DR was significantly higher (P < 0.001) in comparison to patients without DR.

Gender was not identified as a risk factor in our study, which agrees with a study conducted by Rajab[9] demonstrated that women had significantly higher rate of DR than men. Other studies have suggested insignificant differences in DR by sex, which disagree with current study. Vinícius *et al* [14] reported that Mean age of group case was 59.5 years with a slight female predominance, however gender, age and were not associated with higher chances of DR. Also Tawfeeq indicated [8] that, there was no significant differences between the rate of males and females in this study (P>0.5) which was disagreed with our finding.

The study displayed that the highest mean of BMI was recorded in diabetic retinopathy patients compared with control group and diabetic without retinopathy patients, although the result was non-significant. In agreement with current study's findings, Maghbooli et al [15] & Wang et al [16] demonstrated that insignificant association between BMI and DR .Also, Dipayan et al[17] reported that no significant relationship between DR and BMI.

Additionally, Zhou et al [18] demonstrated that elevated BMI did not increase the risk of DR . However, since being overweight and obesity are risk factors for multiple diseases, it is still imperative to maintain a healthy weight. Obesity has also been observed to have detrimental effects on multiple eye diseases such as glaucoma, late age-related maculopathy, and cataracts[19].

BMI has been implicated both for positive and negative relation. Joel et al [20] & Rooney et al [21] showed that an inverse association between obesity and incident DR and also between BMI and DR. As well as, Zahra et al [22] & Jun et al [23] demonstrated that BMI had inverse relationship with DR, so Elevated BMI may confer a protective effect on DR through many ways. First, increased C-peptide levels were found in higher BMI individuals,[58] which could reduce the risk of DR. Moreover, a higher BMI may be a reflection of better glycemic control or shorter diabetes duration. Obese individuals were also more vulnerable to suffer from comorbid conditions; consequently, aggressive treatments have been taken, and reduced the development of DR[24].

Meta-analysis of prospective cohort studies done Wei Zhuby et al [25] suggest that obesity was a risk factor for DR. A higher BMI may have adverse effects on DR. First, an elevated BMI is often correlated with hypertension and dyslipidemia, both of which are risk factors for DR. Additionally, hyperleptinemia in obese individuals may increase blood pressure and oxidative stress levels, which may partly be responsible for the development of DR. Moreover, higher vascular endothelial growth factor levels were observed in obese individuals, which has been shown to be involved in the pathogenesis of proliferative DR[26].

In the current study, the highest mean of MDA were recorded among diabetic retinopathy patients compared with diabetic without retinopathy patients and control group. These findings were close to that reported Dharmveer *et al*[27] indicated a highly significantly increased MDA levels, in diabetic retinopathy patients with respect to controls. Also agreed with study done by

. Shaikh *et al* [28] indicated Serum MDA was significantly elevated in diabetic retinopathy patients compared with control group.

Additionally, Chatterjee *et al*[29], *Vlatka et al* [30] and Manish *et al* [31] indicated a highly significantly increased MDA levels, in diabetic retinopathy patients with respect to diabetic without retinopathy patients, point towards a role of free radicals in causation of diabetic complications like retinopathy. Nair *et al* [32] & Al-Duais *et al* [33] revealed signifcantly higher MDA in diabetics compared to control and similarly in diabetic retinopathy compared to those without DR. Also, Asmat *et al* [34] & Dos Santos *et al* [35] reported that Oxidative stress play a vital role in the pathogenesis of diabetes, oxidative stress harmfully affects the insulin activity through several interacting pathways and generating ROS. These could deteriorate the islets β-cells of the pancreas resulting in the reduced release of insulin. In addition, Free radical formation by non-enzymatic glycation of proteins, glucose oxidation and increased lipid peroxidation leads to damage of enzymes, cellular injury machinery, changes in the cell membrane and increased insulin resistance which are risk for diabetes. Fonseca *et al* [36] MDA is a marker of lipid peroxidation which reacts with cell membrane phospholipids. The elevated level of MDA is found in different pathological diseases such as diabetes, cardiovascular diseases, renal disease, neurodegenerative disorders and cancer so that it is a good biomarker of oxidative stress and tissue damage. Hadeel *et al* [37] revealed significantly higher MDA in diabetics compared to control and similarly in diabetic retinopathy compared to those without DR, and MDA can use for the prognosis of DR, in addition, malondialdehyde may be independent predictor of diabetes and DR.

Chatziralli *et al* [38] and Manish *et al* [39] showed that, serum MDA has been found to be significantly associated with the severity of DR in patients with *type 2* insulin-dependent DM. Marcino *et al* [40] reported that increased MDA is associated with oxidative stress and poor antioxidant defense, which promotes the progression of DR to its proliferative form. María *et al* [41] reported that retinal microvascular complications are closely related to the severity of oxidative stress, as expressed as increased level of MDA among DR patients. Olvera *et al* [42] reported that the exact mechanism by which the oxidative stress contributes to diabetic complications remains unclear, but all biochemical alterations due to DM lead to anatomical and functional impairment in the retinal microvascular network, such as changes in blood flow in the retina, disruption of the blood-retina-barrier and consequently capillary occlusion and ischemia.

The current study showed that, HbA1c was elevated significantly ($P<0.05$) in diabetic retinopathy patients compared with control group and diabetic without retinopathy patients. In agreement with the current results, study done by Dharmveer *et al* [27] showed that increased HbA1c levels in diabetic retinopathy patients as compared to control healthy group and the results were statistically significant . As well as, Namir *et al* [43] showed that significant increase of HbA1c in diabetic retinopathy patients as compared to control group.

Manish *et al* [39] showed that HbA1c significantly increase in diabetic retinopathy patients compared to diabetic without retinopathy patients. Also agree with study done by Ojoye *et al* [44] showed the mean value of HbA1c for Type 2 diabetics were significantly higher ($p< 0.05$) when compared with that of the control group. Goyal *et al* [13] showed that the % of HbA1C measured in DR patients was significantly higher than non-DR patients evidencing the fact that long term poor control of blood sugar levels had adverse effect on retina (8.16 ± 0.52 vs. 7.04 ± 0.32).

Additionally, Xing *et al* [45] revealed that HbA1c were higher in diabetic retinopathy than in diabetic non retinopathy patients and HbA1c were associated with increased risk of diabetic retinopathy. A longitudinal observation study in Southeast Sweden done by Maria *et al* [46] reported that Long-term weighted mean HbA1c, measured from diagnosis, is closely associated with the development of severe complications in type 1 diabetes. Keeping HbA1c below 7.6% (60 mmol/mol) as a treatment target seems to prevent proliferative retinopathy for up to 20 years. As well as, retrospective cohort study done by Ki-Ho *et al* [47] showed that the mean HbA1c levels was higher in the diabetic retinopathy progressors than in the diabetic retinopathy non-progressors . The mean HbA1c was a significant predictor for DR progression independent of the duration of diabetes . In agreement with the current study Bhasker *et al* [48] reported that the HbA1c was found to be higher in diabetics without retinopathy as compared to controls ($p<0.05$) and the highest value was seen in the mild NPDR group . Study done by Nam H *et al* [49] showed that HbA1c cutoff of (6.6 %) and (6.9 %) best detected the presence of any diabetic retinopathy and moderate/severer retinopathy, respectively. Also study

done by Khalid *et al* [50] showing that HbA1c was raised in patients having diabetic retinopathy (p<0.001) and patients who have uncontrolled diabetes (high HbA1c levels) have 66.61% chance of developing the diabetic retinopathy, so HbA1c is a good indicator of glycemic control as it can help diabetic individuals in deterrence of microvascular complications especially DR.

A study done by Lokesh *et al* [12] reported that lower frequency of DR in patients with lower HbA1c group and increase in frequency of DR as the HbA1c increases . As well as, A study done by Leske et al[51], in Barbodose eye study, they found that every 1% increase in HbA1C from baseline was associated with a >2-fold risk of DR, up to 4 years of follow up which was correlating with the present study in telling the linear relationship of HbA1c levels with the development of DR.

The present study displayed that the highest mean of duration of DM was recorded in diabetic retinopathy patients (mean±SD) (13.48±6.00) compared with Diabetic without retinopathy patients (mean±SD) (6.34±2.78), the result was significant (P:<0.05). These findings were close to that reported Goyal *et al* [13] showed that a significant difference was observed in the mean duration of diabetes (12 ± 5 vs. 8 ± 5 years, (P<0.05). Additionally, study done by Yan Liu *et al* [11] showed that patients were getting less likely to suffer from DR every 10 years after 60 years of age, while no difference was found before age 60. Ojoye *et al* [44] reported that the increasing duration of the diabetes mellitus further depresses the antioxidative system. As the disease condition progresses, antioxidative parameters SOD and GPx shows significantly decreasing with increasing years of illness, with the decrease most evident in those affected for the period of 16-20years. This could be the result of increased production of ROS and also increased glycation of the enzymes.

[2]Professor, Depertmant of Medicine, College of Medicine, Tikrit University, Tikrit,, Iraq

Abstract

Background: Psoriasis is a skin disease that was associated with metabolic and clinical changes which suggest that psoriasis is a systemic rather than local disease.

Aim: To illustrate whether psoriasis is local or systemic disease through analysis of some biomarkers.

Materials and Method: A 256 subjects with psoriasis and 221 sex and age matched controls were included in the study. Serum total cholesterol [TC], high density lipoprotein [HDL], Malondialdehyde [MDA], triglycerides [TG], and total antioxidant capacity [TCA] were determined using commercial kits.

Results: There were no significant differences between psoriasis and control groups in regards to mean age and gender distribution, however, there was a significant difference [p<0.01] in BMI. Additionally, TC, TG, LDL and NHDL were significantly higher [P<0.001] in patients with psoriasis than in controls, while HDL was significantly lower in psoriasis than in controls. MDA mean serum level was significantly higher [P<0.001] lower while TCA value was significantly [P<0.001] lower in subjects with psoriasis as compared controls. Lipid profile rates and oxidation index were significantly higher in psoriasis than in controls, while the anti-oxidation index was significantly lower in psoriasis.

Conclusion: These study findings suggest that psoriasis may be a systemic disease rather than local skin disease.

Keywords: *Psoriasis, Cholesterol, LDL, HDL, NHDL, MDA, Total antioxidant capacity.*

Introduction

Psoriasis is a chronic inflammatory- immunologic disease with a prevalence of 2.3% in Iraqi population[1], and variable global prevalence[2]. Although the disease is recognized as local skin disease in approximately 80% of cases, however, 20% of the affected individuals are with >10% body surface area is involved [3]. The disease is with obscure aetiology, however, immunological, genetic, infectious and environmental factors may play a role in the development of psoriasis[4-6]. Previous studies indicated that psoriasis started as local skin disease and subsequently associated with systemic inflammatory-immunologic and metabolic changes[7, 8]. The systemic changes in patients with psoriasis were reported in studies conducted in Iraqi population [5,6,9,10] and worldwide[11-25]. The data presented in the above studies that are from different global communities indicated that psoriasis co-morbidities development are not confined to specific race, developing or developed communities. Previous studies conducted in Iraqi community included small study population, thus this study was conducted in a large-scale study population in comparison with controls.

Materials and Method

Study Population: The present study included 256 subject with psoriasis attending Dermatology clinic

during the period from January 2012 to end of May 2014. A 221 subject, gender and age matched control were included in the study. The mean age of patients group was 34.8 (±15.6) years and that of control group was 34.5 (±14.9) year with none significant difference between the two groups. Additionally, the gender frequency rate was not with significant difference, Table 1. The study was approved by the ethical committee of Tikrit University College of Medicine and informed consent was taken from each subject included in the study. Subjects with diabetes, hypertension, cardiovascular disease, smoking, renal disease, liver disease, family history of hyperlipidaemia, hypothyroidism, connective tissue disease, and using lipid lowering drugs were excluded from enrolment in the study.

Determination of total cholesterol: Total cholesterol serum level was determined by an enzymatic colorimetric test kit [BioMaghreb, France] and the test was performed according to manufacturer instructions.

Determination of high density lipoprotein: High density lipoprotein serum level was determined by colorimetric test kit [LINEAR CHEMICALS S.L. Joaquim Costa 18 2ª planta. 08390 Montgat, Barcelona, SPAIN] and the test was performed according to manufacturer instructions.

Determination of triglycerides: Triglycerides serum concentration was determined by enzymatic colorimetric test kit [Linear Chemicals, Spain].

Determination of Malondialdehyde: Malondialdehyde serum concentration was determined by measuring the thiobarbituric acid reactive substances as described by Janero [26].

Determination of total antioxidant capacity: The serum concentration of Total Antioxidant Capacity was determined according to method described previously by Kampa et al [27].

Determination of very low density lipoprotein: Very low density **was** calculated by division of triglycerides by 5.

Determination of low density lipoprotein: Serum LDL concentration was calculated by subtraction of HDL and VLDL from total cholesterol serum level.

Statistical Analysis: Variables values were presented as mean ± standard deviation [SD]. Student t test was used to determine the significant differences between the groups. P value of <0.05 regarded as significant.

Results

There was a significant higher difference [P<0.001] in mean serum values of total cholesterol (TC), triglyceride (TG), low density lipoprotein (LDL) and non-high density lipoprotein (NHDL) in psoriatic subjects as compared to controls, Table 2. In contrast, high density lipoprotein (HDL) was significantly lower in psoriatic individuals than in controls, Table 2. Additionally, the lipid profile rates were significantly higher [P<0.001] in psoriasis as compared to control group, Table 2. All rates mean values about 2 times higher in psoriasis than in controls.

Malondialdehyde as a marker of oxidative stress was significantly higher [P<0.001] in psoriasis than in controls and thus the oxidation index was 3 times higher in psoriasis with a highly significant difference, Table 3. In contrast, total antioxidant capacity was significantly lower in psoriasis than in controls, with a much lower anti-oxidation index [P<0.001] in psoriasis in comparison to controls, Table 4.

As shown in Table 5, there was a significant [P=0.041 to <0.001] differences in mean serum triglyceride, TAC, BMI, Age, and HDL between male and female psoriatic individuals.

Comparison of male psoriatic with male controls indicated a significant differences [P<0.001] in all tested variables, Table 5. The same pattern was demonstrated when female psoriatic compared to female controls, with the exception of BMI, Table 6. Lipid profile, oxidation, and anti-oxidation rates were significantly different between psoriasis and controls.

Discussion

The peroxidation biomarkers as this study indicated were significantly higher in psoriatic patients as compared to controls. Additionally, gender not significantly influenced the differences in peroxidation biomarkers as demonstrated by comparative analysis on different strata. There was a significant difference when male patients compared to male control; female patients compared to female control, however, there was no significant differences in comparison between the male psoriatic and female psoriatic. These findings were in consistent with that reported previously for different

geographical areas [5-25, 8], irrespective of race, gender, and age.

The antioxidant activity as measured by TAC, HDL, and antioxidant index calculation show a significantly low capacity in psoriatic patents than in control. This finding was agreed to that reported for Iraq and other geographical areas [5-25; 28,29,30], however, some studies not confirmed such changes [15,31-33]. The genetic predisposition may form the first step in the development of psoriasis, and environmental factors interference possibility may initiate disease specific pathogenicity and disease natural history [7].

In literature, the previous studies findings suggest that psoriasis is a multisystem chronic disease with multifactorial aetiology and associated with different comorbidities that were a result of inflammatory, immunologic and infectious sequences [8,32-34].Although psoriasis was characterised by local skin lesions due to inflammatory and immunological responses, however, this study and the previously reported studies indicated that systemic changes were more than dermatologic one [34]. Sing et al [16], in a meta-analysis review reported that from 36 studies, only 1 show odd ratio of <1, and 35 studies with OR range from 1.09 to 6.09 and 21 studies with OR of >2 were demonstrated as association with metabolic syndrome.

Reich [7] 2011, in a review concluded the presence of similarities in pathogenesis of psoriasis and atherosclerosis and suggests that psoriasis is a systemic inflammatory disease. Psoriasis patients are with high prevalence of hypertension, diabetes, hyperlipidaemia, obesity, ischemic heart disease, rheumatoid arthritis and Crohn's disease[35, 36]. Davidovici et al [37] proposed a model that suggest a presence of shared genetic risk factors between psoriasis and obesity and enhance co-morbidities development.

Tampa et al [32] in a review concluded that stress was an important trigger for psoriasis, and many studies suggested the association between psoriasis and psychological stress [16,38-45]. However, the psychological stress mechanisms by which psoriasis induced or exacerbated was not completely understood [32]. Immunopsychological studies show that stress affects immune functions and hormones with subsequent events of in B lymphocytes, T lymphocytes, monocyte, cytokines and oxidative stress biomarkers [46-59]. In Iraqi population, 67% of psoriatic patients demonstrated high perceived stress scale as compared to non-psoriatic patients [60]

Cantrell et al [61] suggested that psoriasis was a systemic inflammatory disease depending on the recent studies that reported an association with cardiovascular diseases, metabolic syndrome, hypertension, psoriatic arthritis, dyslipidemia, and renal diseases[24,62-69]. Additionally, Sanz[70], concluded that psoriasis is a systemic diseases and this conclusion was attributed to the significant association between systemic disease and psoriasis as recent studies indicated. The comorbidities associated with psoriasis include psoriatic arthritis[71-74], crohn disease[75,76], and lymphoma[77-80]. Psoriasis treatment with systemic drugs modified the risk factors such as cardiovascular disease and arthritis risk reduction[62-86].

In conclusion, the present study findings indicated systemic oxidative stress in patients with psoriasis with reduction in antioxidant capacity. Collectively these findings and that of previous studies and ameliorations of biomarkers by systemic treatment suggest that psoriasis is a systemic disease.

Table 1. Study population characteristics

Variable	Psoriasis	Control	P value
Number	256	221	---
Male/female	137/119	113/108	>0.05
Mean age in year (SD)	34.8 (15.6)	34.5 (14.9)	>0.05
Mean BMI (SD)	26.7 (1.3)	25.4 (1.5)	<0.01

Table 2. Mean of Lipid profile with rates in psoriatic patients compared to control

Variable	Mean (SD)		t value	P value
	Psoriasis	Control		
Total cholesterol mg/dl	218.6 (15.6)	184.3 (27.6)	17.13	<0.001
Triglyceride mg/dl	174.2 (15.7)	123.7 (24.8)	26.51	<0.001
HDL mg/dl	40.6 (4.3)	55.2 (9.7)	20.84	<0.001
LDL mg/dl	143.5 (35.6)	104.2 (17.1)	15.12	<0.001
NHDL mg/dl	178 (37.9)	129.1 (18.5)	17.38	<0.001
Cholesterol/HDL	5.5 (1.4)	3.3 (0.2)	23.15	<0.001
LDL/HDL	3.6 (1.3)	1.9 (0.1)	19.38	<0.001
Triglyceride/HDL	4.4 (0.9)	2.2 (0.5)	32.28	<0.001
NHDL/HDL	4.5 (1.4)	2.4 (0.2)	22.10	<0.001

Table 3. Malondialdehyde and total antioxidant capacity in psoriatic patients compared to control

Variable	Mean (SD)		t value	P value
	Patients	Control		
Malondialdehyde µmol/l	4.6 (0.7)	2.3 (0.3)	45.3	<0.001
Total Antioxidant Capacity µmol/l	755 (121)	1045 (194)	19.8	<0.001
Oxidation Index	6.09 (1.2)	2.2 (0.8)	40.1	<0.001
Anti-oxidation Index	164.1 (17.3)	454.3 (59.7)	74.5	<0.001

Table 4. Lipid profile, age, Malondialdehyde, Body Mass Index and Total Antioxidant Capacity in psoriasis according to gender

Variable	Mean (SD)		t value	P value
	Male	Female		
Cholesterol	217.1 (35.7)	221 (32.8)	0.9	>0.05
Triglyceride	179 (15.4)	158 (7.2)	13.6	<0.001
HDL	40.3 (4.9)	41.6 (4.7)	2.1	0.031
LDL	142 (37.1)	145 (34.8)	0.7	>0.05
NHDL	177 (38.9)	179 (37.5)	0.4	>0.05
Age	34.1 (4.7)	35.7 (7.6)	2.1	0.041
BMI	27 (1.58)	26.4 (2.6)	2.3	0.024
Malondialdehyde	4.6 (1.1)	4.5 (0.51)	0.9	>0.05
Total Antioxidant Capacity	702 (83.6)	737 (132.8)	2.5	0.011

Table 5. Lipid profile, age, Malondialdehyde, Body Mass Index and Total Antioxidant Capacity in psoriatic male compared with control male

Variable	Mean (SD)		t value	P value
	Male psoriasis	Male control		
Cholesterol	217.1 (35.7)	185 (16.1)	8.7	<0.001
Triglyceride	179 (15.4)	128 (22.1)	21.2	<0.001
HDL	40.3 (4.9)	57 (2.1)	31.1	<0.001

Variable	Mean (SD)		t value	P value
	Male psoriasis	Male control		
LDL	142 (37.1)	104.7 (9.6)	10.0	<0.001
NHDL	177 (38.9)	129 (17.5)	12.0	<0.001
Age	34.1 (4.7)	31 (3.7)	5.5	<0.001

IL-6, IL-0, IFN Gamma and CRP in Newly Diagnosed COVID 19 Patients

Mazin Jabbar Kathim[1]; Tamara Amer Taha[2], Suzan Saadi Hussain[3], Nihad Khalawe Tektook[4]

[1]Department of Orthopaedic Surgery, Fallujah Technical Hospital, Inbar, [2]Lecturer, College of Basic Education, University of Diyala, [3]Prof., College of Science, Mustanisiriyah University, [4]Assist. Prof. Middle Technical University, College of Medical and Health Technology, Medical Laboratory Techniques Dep., Baghdad-Iraq

Abstract

The study was conducted in Baghdad for the period from July 1 to August 20 2020 on patients previously diagnosed with the emerging corona virus .. The study included 40 patients whose ages ranged from 20 to 80 years. The study also included taking 40 healthy people of the same age groups to detect interleukin 6 and 10 gamma interferon by using ELISA technique as well as measuring the level of the C-reactive protein. The study contained a withdrawal of five ml of venous blood from patients and patients and took all the necessary information from them such as gender, age, current living status, number of family members, as well as the history of infection and travel to countries affected by the virus to compare the two groups with regard to the immune response by measuring the variables above. The study showed that the highest mean level of IL-6 was found in newly diagnosed COVID-19 patients comparing with healthy control (60.76±8.46 *v.s.*39.03±5.26 pg/ml) (P:<0.01). The study also demonstrated that the level of IL-10 was significantly elevated in newly diagnosed COVID-19 patients as compared with healthy control (38.18±4.57 *v.s.*31.84±3.19 pg/ml). The study established that the level of IFN-Gamma was significantly increased in patients with new infection of COVID-19 as compared with healthy control (27.27±7.18 *v.s.* 13.81±3.83 pg/ml) (P:<0.01). The study proven that the level of CRP was increased significantly in patients with new infection of COVID-19 as compared with healthy control (33.18±3.19 *v.s.*3.±1.81 mg/dl) (P:<0.01). The study concluded that, There was a highly significant relation of IL-6, IL-0, IFN gamma, and CRP with COVID-19 disease in the first week of infection

Keyword: *COVID-19; SARS COV2; IL-6; IFN gamma; CRP.*

Introduction

The presence of a new virus belonging to the Coronavirus family was announced at the end of 2019 in Wuhan, China, and it was recently agreed to name it as Covid-19, SARS-Coronavirus2[(1)]. It was declared by the World Health Organization (WHO) as an epidemic that spread rapidly around the world and raised international concern and raised the state of emergency in all countries that it entered due to its rapid spread and the lack of clarity of all signs of infection as it is a new virus that infects humans and is transmitted from animals and then transmitted between humans and humans [(2)]. The genetic sequence of the virus represents a 96% and 79.5% match for the bat coronavirus and SARS-CoV, respectively. Such as SARS-CoV and MERS-CoV. The previous evidence also showed that most patients have shown that the level of cytokines and immune proteins are among the most important causes of patients 'recovery first, and then it is possible that these cytokines will do the opposite in the deterioration of the disease by forming the so-called cytokines storm[(3,4)]. However, until this moment, there are scarce studies about what the virus is and the true immune role of the host's body towards the

virus, especially as it was presented that the virus is new and information about its pathogenicity is not available in an accurate and clear way[5]. Studies indicate that the COVID-19 virus was more likely to affect adults of older ages and the elderly who have associated diseases such as diabetes, high weakness, heart and lung problems, and whose immunity is low due to the presence of those diseases that are characterized by low immunity [6, 7]. Especially since the virus is a virus with a new strain that has not yet been known about the true condition of the infected, the high rates of infection and the spread of disease among groups of society and the elderly in particular, and that the high levels of inflammatory cytokines among people with the good coronavirus and not many people know about the nature of the immune response for patients infected with the emerging coronavirus[8]. So the aim of the study was to estimate the level of IL-6, IL-0, IFN gamma and CRP in patients with COVID-19 infection.

Material and Method

The study was conducted in Baghdad for the period from July 1 to August 20 2020 on patients previously diagnosed with the emerging corona virus .. The study included 40 patients whose ages ranged from 20 to 80 years. The study also included taking 40 healthy people of the same age groups to detect interleukin 6 and 10 gamma interferon by using ELISA technique (Koma biotech, ELISA, USA).as well as measuring the level of the C-reactive protein. The study contained a withdrawal of five ml of venous blood from patients and patients and took all the necessary information from them such as gender, age, current living status, number of family members, as well as the history of infection and travel to countries affected by the virus to compare the two groups with regard to the immune response by measuring the variables above.

Findings: As shown in Table 1. There was no significant difference between studied cases and the control group regarding patient age.

Table 1: Clinical characteristics of studied women

Parameters (Mean±SD)	Pregnant women	Control group
No.	40	40
Age (yeas)	52.1±6.7	50.6±5.6
Sex	35 male, 15 female	33 male, 17 female
Mean 24 h SBP, mm Hg	128.7±11.5 *	110.8±7.4
Mean 24 h DBP, mm Hg	83.5±6.9*	69.4±8.3
Maximal SBP, mm Hg	167±24.1*	119.0±10.2
Maximal DBP, mm Hg	109.1±22.7*	74.7±13.3

The study showed that the highest mean level of IL-6was found in newly diagnosed COVID-19 patients comparing with healthy control (60.76±8.46*v.s.*39.03±5.26 pg/ml) (P:<0.01).

Table 2: Levels of IL-6 in newly diagnosed COVID-19 patients and the control group

Group	Mean (pg/ml)	SD	P value
COVID-19 patients	60.76	8.46	<0.05
Healthy group	39.03	5.26	

The study also demonstrated that the level of IL-10 was significantly elevated in newly diagnosed COVID-19 patients as compared with healthy control (38.18±4.57 *v.s.*31.84±3.19 pg/ml) (P:<0.01), Table 3.

Table 3: Levels of IL-10 in newly diagnosed COVID-19 patients and the control group

Group	IL-10 Mean (pg/ml)	SD	P value
COVID-19 patients	38.18	4.57	<0.05
Healthy group	31.84	3.19	

The study established that the level of IFN-Gamma was significantly increased in patients with new infection of COVID-19 as compared with healthy control (27.27±7.18 *v.s.*13.81±3.83 pg/ml) (P:<0.01), Table 4.

Table 4: Levels of IFN-Gamma in newly diagnosed COVID-19 patients and the control group

Group	IFN-Gamma Mean (pg/ml)	SD	P value
COVID-19 patients	27.27	7.18	<0.05
Healthy group	13.81	3.83	

The study proven that the level of CRP was increased significantly in patients with new infection of COVID-19 as compared with healthy control (33.18±3.19 *v.s.*3.±1.81 mg/dl) (P:<0.01), Table 5.

Table 4: Levels of CRPin newly diagnosed COVID-19 patients and the control group

Group	CRP Mean (mg/dl)	SD	P value
COVID-19 patients	33.18	3.19	<0.05
Healthy group	4.17	1.81	

Table 5: Correlation of CRP with each parameter in the study

Parameter	R value
IL-6	0.7
IL-10	0.52
IFN-Gamma	0.49

Discussion

In this study, levels of IL-6, IL-0, IFN gamma, and CRP were increased in subjects with coronavirus, and I mean Yen, who was newly diagnosed with the virus by nasopharyngeal swab examination and polymerase chain reaction method. It should be noted that the observed increase in the levels of g variables. Several very recent global responses indicate that IFNγ and IL-6 F levels are positively associated with an increased infection with the Covid 19 virus that causes acute respiratory syndrome (9). Other studies suggest that an excess of these cytokines and other inflammatory agents may cause the body to create a so-called cytokine storm (10, 11). While this virus multiplies in the cells of the upper respiratory system and then descends gradually until it reaches the internal lung tissues, the increase in the secretions of cytokines above may lead to acute respiratory distress syndrome associated with the new corona virus as a result of bulimia and acute reproduction. From a virus with induction of conventional antiviral immunity and with a crisis associated with a possible peak phase of T cell responses. However, it is not clear whether immune hyperactivity or failure to resolve the inflammatory response due to persistent viral replication or immune dysregulation underlies severe disease (12). Several recent responses undertaken to determine the role of immunity and the immune response to Covid-19 indicate that interleukin-6 and CRP are elevated in patients with COVID-19, particularly those with comorbidities such as diabetes and chest and vascular pain (13-16). Other studies have also indicated two settings induced by viral infection and epithelial cell proliferation in the airway in high levels of viral-associated acid inflammation with associated vascular leakage, as seen in SARS-CoV53 patients. Prostatitis is a highly inflammatory form of programmed cell death that is commonly observed with cytokine viruses 54. This is a potential trigger for a subsequent inflammatory response (17, 18). It is worth noting that another study conducted in advance during the past few months reported that the highest levels of serum inflammatory cytokines, interleukin-6 and CRP were in patients diagnosed with severe Covid-19 compared to individuals with mild disease, similar to the

results of our study that confirmed this, which stated that There was a significant positive correlation of CRP with all cytokines that were taken in the current study (19). Some scientists believe that the rise of these pathogens, in addition to other factors that have not been taken into account, may play a vital role in the fluctuation of autoimmunity first, then the original immunity in patients infected with the new coronavirus, Covid 19 (20). Although there was no direct evidence that cytokines and inflammatory chemicals were involved in lung disease during COVID-19, changes in laboratory parameters, including elevated blood cytokines, chemokine levels, and increased CRP in affected patients, were associated with disease severity and adverse outcomes(21).

Conclusions

Levels of IL-6, IL-0, IFN gamma, and CRPwere elevated significantly in patients with COVID-19 disease in the first week of infection

The Value of Measurment of Bilirubin in Pleural Fluid in the Differentiation between Exudative and Transudative Pleual Effusion

Bint Al huda A. Jaber[1], Khalid Abd Alstar Hussein[2], Zahrah Salih[3]

[1]M.B.CH.B. Respiratory/Ibn Alnafes Cardiovascular Teaching Hospital, [2]MSc. Cardiology. MBCHB Cardiologist/ Ibn Alnafes Cardiovascular Teaching Hospital, [3]M.B.CH.B Anesthesiologist

Abstract

Background: The pleural effusion is a common clinical problem which can be exudative or transudative in nature due to variety of causes. Measurement of biochemical markers in the pleural fluid is an important measure to distinguish exudative from transudative effusion.

Aim of the Study: Is to determine the value of pleural fluid to serum bilirubin ratio to differentiate between transudative and exudative pleural effusion.

Patients and Method: Thirty-five patients enrolled in this study, they admitted to medical ward in Baghdad teaching hospital and submitted to clinical, radiological, ultrasonographic examination proved to have pleural effusion from December 2018 to July 2019. Samples of blood and pleural fluid aspirated in the medical ward, analyzedafter 30-60 minute of aspiration. The sample of some cases were analyzed in private laboratories. Serum protein, total serum bilirubin and other investigation according to the condition of the patient like blood urea, serum creatinine, liver function test, sputum of AFB. Pleural fluid analyzed from protein, total bilirubin, cell count, differential and cytology .Pleural biopsy was done to patients suspected to have malignant or tuberculous effusion and grouped at the end of their hospitalization into exudative and transudative effusion according to specific etiology, clinical examination, radiological finding, and then measure the pleural fluid to serum protein ratio, pleural fluid to serum bilirubin for each patient. We depended on pleural fluid to serum protein ratio to compare with pleural fluid to serum bilirubin ratio for differentiation between exudative and transudative pleural fluid.

Results: Twenty two patients with exudative effusion and thirteen patients were having transudate according to pleural fluid to serum protein (Light 's criteria). P-value= 0.002, Fisher. Exact test= 0.001. Twenty three patients with exudative effusion and twelve patients with transudative effusion according to pleural fluid to serum bilirubin ratio. P value= 0.37, Fisher. Exact test = 0.45. Pf/s ratio can increase the sensitivity and specificity of Light 's criteria.

Conclusions: Pleural fluid to serum bilirubin ratio can't replace Light's criteria in differentiation between exudates and transudate pleural effusion. Pf/s bilirubin ratio is a reliable test can easily perform but not common use in our hospital because of its costy and not familial use in our laboratories.

Introduction

The pleural lining is a serious membrane covering the lung parenchyma, chest wall, diaphragm, and mediastinum. The pleural membrane covering the surface of the lung is known as visceral pleura, whereas the parietal pleura cover the remaining mentioned structures. In between the visceral and parietal pleura is the pleural space, a potential space that contain a thin layer of fluid (approximately 0.15 ml/kg/pleural space) usually around 10 ml in each pleural space. The parietal pleura secrete approximately 2400 ml of fluid daily, which is reabsorbed by the visceral pleura[(1).]A

pleural effusion is present when there is an excess quantity of fluid in the pleural space. [2].Pleural fluid accumulates when pleural fluid formation exceeds pleural fluid absorption; fluid enters the pleural space from the capillaries in the parietal pleura and is removed via lymphatic situated in the visceral pleura. Fluid can also enter the pleural space from the interstitial space of the lung via the visceral pleura or from the peritoneal cavity via small holes in the diaphragm. The lymphatics have the capacity to absorb 20 times more fluid than is normally formed. Accordingly pleural effusion may develop when there is excess pleural fluid or peritoneal fluid or when there is decreased fluid removal by the lymphatics. [1]. The distinction between a transudative and exudative pleural fluid is an important step in the diagnosis of the cause of the pleural effusion by using various parameters, like Light's criteria (1972) p/f is exudate if one or more of the following criteria are met [3,4]. (Pleural fluid protein/serum protein > 0.5, Pleural fluid LDH/serum LDH >0.6,Pleural fluid LDH > two-third of upper limit of normal serum LDH)A pleural fluid to serum bilirubin ratio of more than 0.6 was suggested as an alternative to Light's criteria for distinguish exudates from transudate pleural fliud.Dyspnea is the most common symptom associated with pleural effusion, it related more to distortion of the diaphragm chest wall during respiration than to hypoxemia. In many patients drainage of pleural fluid alleviate symptoms despite limited improvement in gas exchange.Chest symptoms of pleural effusion include mild, non productive cough or chest pain . Other symptoms may suggest the etiology of pleural effusion e.g. more severe cough or production of purulent sputum suggest an underlying pneumonia or endobronchial lesion [5].Constant chest wall pain may reflect chest wall invasion by bronchogenic carcinoma or malignant mesothelioma.Pleurtic chest pain suggests either pulmonary embolism or an inflammatory pleural process.Systemic toxicity evidence by fever, weight loss and inanition suggest empyma[6].PHYSICAL EXAMINATION: Restriction in the chest expansion of one side or both sides, Trachea and apex beat may be displaced away from the effusion if it is large, Movement of affected side may be reduced, Percussion note is stony dull, Vocal fremitus and resonance are reduced, Breath sounds are reduced.Initial testing focuses on confirming that a pleural effusion is present. A chest x-ray study is the typical starting point. In the upright anteroposterior view, a small effusion may show up as blunting of the costophrenic angle. Larger effusions show a meniscus sign at the air fluid border. Lateral decubitus views help estimate the size of the effusion [7].Ultrasound can detect as little as 5 to 50 ml of fluid. It is also helpful in locating pockets of fluid and guiding thoracentesis for small effusions. Computed tomography, which is very sensitive, can differentiate pleural fluid from pleural thickening and focal masses[7] . Thoracocentesis allows evaluation of any undiagnosed pleural effusion. Note that not all effusions require diagnostic thoracentesis. If the cause is apparent from the clinical presentation (e.g. CHF), observation may be appropriate [5]. In general, parapneumonic effusions require thoracentesis to confirm diagnosis and assess the need for chest tube placement.

Patients and Method

Thirty-five patients enrolled in this study were admitted to medical ward of Baghdad teaching hospital and submitted to clinical examination and investigation, proved to have pleural effusion in the period from December 2018 to July 2019.Samples of blood and pleural fluid that were aspirate in the medical ward, analyzed after 30-60 minute of aspiration. Some of the cases analysis of their samples done in private laboratories. Serum analysis for protein concentration, total bilirubin and other investigation according to the condition of the patient like blood urea, serum creatinine, liver function, sputum for AFB and cytology. Pleural fluid analyzed for protein, total bilirubin, cell count, differential and cytology. Then calculate the pleural fluid to serum bilirubin for each patient and compare with pleural fluid to serum protein which measured also for each patient. The procedure for measuring protein in pleural fluid is called ZeilfaBiurate method, by taking 1.4 ml distal water mix with 0.1 fluid and 2.5 ml biurate, wait for 10 minuteat room temperature then read the result by spectrophotometer at 540mm. The method for determination of bilirubin concentration in plasma (serum) which is the same use for measurement of total bilirubin in pleural fluid are divided into the method using:-Diazo reagent & DPD (dichlorobenzenediazonium salt) & Bilirubin oxidaze & Direct spectrophotometric determination of bilirubin. The procedure which use in this research is the first one was Van den Berg's reaction with diazobenzenesulfonic acid from 1913. Method have been developed for the determination of total bilirubin (conjugate and unconjugated) or conjugated bilirubin alone. The proportion of unconjugated bilirubin is calculated as difference between total and conjugated bilirubin should previously be separated from albumin by use of an accelerator (methanol, sodium acetate

diphylline, sodium benzoate-sodium acetate-caffeine or detergent, e.g. Brij35) those conjugated bilirubin reacts directly in the reaction of diazotization. Bilirubin diazotization is generally performed by use of mixture of sulfanilic acid and sodium nitrite, however, diazonium salts of 2,5-dichlorophenyl or 2,4-dichloroaniline have recently also been introduced. The determination of bilirubin concentration by use of these method based on the formation of azobilirubin, which acts as an indicator. Is pink in acidic or neutral medium, and blue-green in alkaline medium.

Statical Analysis: Chi square were used to study the variations in the ratio of pf/s protein ratio of different diseases and pf/s bilirubin ratio of different diseases. Also using F. E.t . F-test was used to study the variations of total serum protein, pleural fluid protein, total serum bilirubin and pleural fluid bilirubin.

Results

Table (1): Classification of pleural effusion according to causes.

Diagnosis	No . of patients	Percentage
Pulmonary TB	11	31.42%
Bronchogenic carcinoma	6	17. 14%
Pulmonary Metastasis	5	14. 28%
Pneumonia	2	5 .71%
Undiagnosed		
HF	3	8.57%
RF	6	17.14%
Total	35	100%

Table (1) shows the number of patients with pleural effusion and the causes of their pleural effusion. The number of patient with tuberculous pleural effusion were 11 (31.43%), while those with bronchogenic carcinoma were six patients (17.14%), patients with pulmonary metastasis were five patients (14.28%) of patients with RF were 6 (17.14%) while those patients with heart failure were 3 (8.57%) and those cases undiagnosed were 3 (8.57%).

Table (2): Distribution of cases according to the age

Age (Year)	Number of patients	Percentage
10 - 19	2	5.71%
20 – 29	6	17.14%
30 – 39	3	8.57%
40 – 49	5	14,28%
50 – 59	4	11.42%
60 – 69	10	28.57%
70 - 79	5	14.28%

Table (3):Classification of pl –effusion into exudate & transudat by f/s Brlirubin ratio .

Type of fluid	Value of pf/s B.R	No .of patients	Percentage
Exudate	≥0.6	23	65.71%
Transudate	< 0.6	12	34.28%
Total		**35 Case**	

Table 4: Classification of pl –effusion into exudates & transudate by F/s Protein ratio .

Type of fluid	Value of pf/s pro.R	No .of patients	Percentage
Exudate	≥0.5	22	62.28%
Transudate	< 0.5	13	37.71%
Total		**35 Case**	

Table (5): Distribution of diseases according to ratio of protein in pleural fluid to total serum protein

Diseases	Ratio			
	≥0.5		<0.5	
	No.	%	No.	%
Pulmonary TB	9	81.8	2	18.2
Lung CA	5	83.3	1	
Heart failure	0	0.0	3	100.0
Secondary metastasis	5	100.0	0	0.0
Undiagnosed	1	50.0	1	50.0
Chronic renal failure	0	0.0	6	100.0

Diseases	Ratio			
	≥0.5		<0.5	
	No.	%	No.	%
Pneumonia	1	50.0	1	50.0
Total	21	60.0	14	40.0

c^2=20.5, d.f=6, p=0.002,Fisher `s Exact test=0.001

Table (6): Distribution of diseases according to pleural fluid to total serum bilirubin ratio.

Diseases	≥0.6		<0.6	
	No.	%	No.	%
Pulmonary TB	6	54.5	5	45.5
CA. lung	3	50.0	3	50.0
Heart failure	3	100.0	0	0.0
Secondary metastasis	4	80.0	1	20.0
Undiagnosed	1	50.0	1	50.0
Chronic renal failure	2	33.3	4	66.7
Pneumonia	2	100.0	0	0.0
Total	**21**	**60.0**	**14**	**40.0**

c^2=6.4,d.f=6, p=0.37,Fisher`s exact test=0.45.

Table (1) shows the patients' distribution number according to age which shows that the most common group ranged from (60 - 69) were 10 (28. 57), the second group ranged from (20 - 29) were 6 (17. 14%) while those group range between (40 - 49) were5 (14. 28%) equal to those group ranged between (70 - 79) were 5 (14. 28) and the least number those group (10-19) were 2 (5.71%). To determine whether these cases in my research have exudates pleural effusion or transudate is 0 .6 fluid to serum bilirubin ratio as show in table (3). There are 23 (65.71%) patients with exudative type their f/s ratio of Bilirubin is equal to or more than 0. 6 while those with transudative type are 12 (34.28%) patients their f/s ratio less than 0.6 Table (4) show the cut off point for f/s protein ratio is 0.5. The number of patients whom their f/s equal/or more than 0. 5 are exudative pleural effusion Their number are 22 (62. 28) while those with transudative type have f/s ratio less than 0.5 their number are 13 (37, 71) .

Table (5) shows the distribution of diseases according to ratio of protein in Pleural fluid to total serum protein, Those patient with pulmonary TB occupied We larger number there are nine patients (81.8) with a ratio more than or equal 0 0. 5 and two patients (182) with a ratio less than 0. 5. In bronchogenic Carcinoma only one case misdiagnosed with transudate pleural effusion. p.value = 0.002 . Fisher 's Exact test = 0.001 Table (6) show the distribution of diseases according to level of bilirubin In pleural fluid to total serum bilirubin only six patients of pulmonary tuberculosis catch that have exudative pleural effusion and five of them diagnosed wrongly had transudate pleural effusion when depend on Pf/s bilirubin ratio.also for bronchogenic carcinoma I catch three patients with exudative pleural effusion While other diagnosed wrongly with transudate pleural effusion. p.value = 0.37, fisher 's exact test = 0.45 If the p- value or F. E. T less than 0.05 were consider as significant.

Discussion

The use of several chemical tests to separates transudates from exudates is recommended as a useful first step in determining the cause of pleural effusion. In 1972 Light et al used pleural and serum levels of proteins and LDH to establish criteria for segregation transudates from exudates with a sensitivity and specificity both near 100 percent (19, 20, 21) this high diagnostic accuracy together with a relatively low cost made the criteria of Light et al the gold standard for initial categorization of

pleural effusions. Recently, however, several prospective studies (22, 23) were unable to reproduce the excellent results obtained by Light *etal.,*as show in this study pf/s bilirubin, Bilirubin of molecular Weight of 584 behaves similar to high molecules weight protein with respect to its concentration distribution between serum and pleural fluid (24), Such behavior may be attributed to structural and electrical properties of bilirubin, but it seems that it can not be based sound biochemical reasoning other than the plausible mechanism of protein binding.

This characteristic may explain why the bilirubin and protein ratios concentration in exudative effusion is higher than transudate which reflect serum level in circumstances that increase permeability of pleural membrane, but the biochemical analysis of bilirubin affect by light, duration between taking the sample and analysis When the duration is long or when the sample expose to light, there is more chance for wrong result so when sample of pleural fluid of patient send to be analyzed outside the hospital should protected from light and kept with preserve material (anticoagulant). Also other drawback of this method that there 's no specific method in determination of bilirubin in pleural fluid although there' s different in consistency between serum and pleural fluid. In this research the Pf/s bilirubin ratio was not sufficient alone to differentiate between exudates and transudate pleural fluid in comparison with Pf/s protein ratio (light's criteria). Some vale 200 sensitivity of the test and other give low Sensitivity of the test for e.g. the sensitivity of pulmonary tuberculosis effusion is 94% bronehonic carcinoma as 92% and for parapneumonic effusion is 58%.

Also by stastical analysis using p -value & Fisher's Exact test show no significant result according to Pf/s bilirubin ratio but it give Significant result with Pf/s protein ratio. There is similar study done in clinical biochemistry department in William Harvey hospital using multiple biochemical parameters for differentiation between exudates and transudate pleural fluid. The recommendation of this study shows that the bilirubin is not useful [(8)]. Other Study done in department of chest disease, Cumhuriyet university medical School, Sivas Turkey show that can use different biochemical parameter like measure Pleural fluid and serum levels of albumin, protein, LDH, cholesterol and bilirubin of 381 patient with pleural effusion[(25)]. Also there's thesis prepared by Dr. Hashim Mahdi for degree of fellowship of Iraqi board of medical specialist in internal medicine. These two studies give result reverse to my study that Pf/s bilirubin play a role in distinguish between exudates and transudate and it can increase the sensitivity and Specificity of Light's criteria.Note; there is no facility in the hospital lab. for other biochemical test like LDH, cholesterol, ADA also PH of fluid and because of limited material that use for measure concentration of bilirubin in serum or in fluid,the head master of biochemical department accept one case per week of my research to measure the bilirubin in fluid that's why I deal with limited number of patient and the of my research need large group of patients to asses and reach to good result.

Conclusions

Pleural fluid to serum bilirubin ratio can't replace Light's criteria in differentiation between exudates and transudate pleural effusion. Pf/s bilirubin ratio is a reliable test can easily perform but not common use in our hospital because of its costy and not familial use in our laboratories.

Serum Leptin Level and Thyroid Hormone in Type 2 Diabetes Patients

Hamza Mustaffa Khuder[1], Khudair Abbas Khudair[2], Ammar Lateef Hussein[3]

[1]Student, Bachelor of Medical Lab Science, Collage of Technology, Kirkuk, [2]Ass. Prof. Tikrit Medical College, Community Medicine, [3]Ass. Prof. Tikrit Medical College, Community Medicine

Abstract

Background: Diabetes is a complex, chronic illness requiring continuous medical care with multi-factorial risk-reduction strategies beyond glycemic control. Ongoing diabetes self-management education and support are critical to preventing acute complications and reducing the risk of long term complications(1). Diabetes mellitus occurs when there are raised levels of glucose in aperson's blood because their body cannot produceany or enough of the hormone insulin, or cannot effectively use the insulin it produces. The causes of type 2 diabetes are not completely understood but there is a strong link with overweight and obesity, and increasing age, as well as with ethnicity and family history.Aim: This study intended to assess and study correlation between serum levels of leptin and thyroid hormones in diabetic and obese patients.Subject and Method:a case control study was conducted at the center of diabetes management and research between 1st of December 2019 to the 15th of May 2020. A fasting blood sample was taken from all participants for measurement of biochemical parameters. The information regarding the problem and demographic characteristics was obtained directly from the participants by interviewing them, using a prepared questionnaire. The weight and the height were using a medical scale machine. The body mass index was calculated according to its equation.Results: Results of the present study show that leptin hormone was significantly high in serum of type 2 diabetic patients group compared with overweight and obese group ($P < 0.000$). A significant positive correlation with serum leptin and body mass index. Results also show that TSH hormone ($P < 0.01$), and FBS were significantly high($P < 0.000$), while T3 and T4 decrease significant ($P < 0.05$) in type 2 diabetic patients groupand compared with control groups.

Keywords: *Type 2 diabetes mellitus, Leptin, thyroid hormone.*

Introduction

With the increasing incidence of obesity and type 2 diabetes mellitus in the Iraq and abroad, We should focused on the molecules and pathways that regulate metabolic homeostasis with the hope of identifying a pharmacological target to limit obesity and diabetes, and/or its pathophysiological consequences. Diabetes is a major health issue that has reached alarming levels: today, nearly half a billion people are living with diabetes worldwide(1). It is one of the major health priority of the 21st century (2)causing 1.5 million deaths in 2012(3) and 4.2 million deaths resulting from diabetes and its complications in 2019 (2).Diabetes can be classified into the following general categories: Type 1 diabetes (due to autoimmune b-cell destruction, usually leading to absolute insulin deficiency), Type 2 diabetes (due to a progressive loss of adequate b-cell insulin secretion frequently on the background of insulin resistance) and Gestational diabetes mellitus(4). Type 2 diabetes is most commonly seen in older adults, but is increasingly seen in children and younger adults owing to rising levels of obesity, physical inactivity and inappropriate diet(5,6). In another word, a consequence of social trends toward higher energy intake and reduced energy expenditure(4,7). Obesity is a rapidly growing health problem, conferring substantial excess risk for morbidity and mortality, especially from type 2 diabetes and atherosclerotic cardiovascular disease (CVD)(8). Studies on both humans and animal models have demonstrated close associations between obesity and a state of low-grade, chronic inflammation characterized by macrophage infiltration in adipose tissue and increased circulating

concentrations of pro-inflammatory molecules, including acute-phase proteins, cytokines, adipokines (like leptin), and chemokines [9]. Leptin is a cytokine-like (16kDa) polypeptide produced by the adipocyte that controls food intake, leading to the suppression of appetite[10], energy expenditure, and, hence, body weight through the activation of hypothalamic receptors[11]. Women have higher leptin concentrations than men. But after menopause a significant reduction in the amount of circulating leptin occurs [12]. Such sexual differences can be explained by the difference in fat mass, body fat distribution, and sex hormones[13]. Mean concentration in women is 12.7 mg/L while it is 4.6 mg/L in men[14].Leptin has been found increased in subjects with hyperinsulinemia and type 2 diabetes, and showed a positive association with triglycerides, systolic and diastolic blood pressure[15]. Within the endocrine system, leptin regulates the circadian rhythms of the gonadotropic, thyrotrophic and adrenal axes. It also plays key roles in the regulation of glucose homeostasis and insulin sensitivity, independent of actions on food intake, energy expenditure or body weight[16,17]. Also the hypothalamic _thyroidal axis is regulated by leptin. This provides an important interface between adiposity, regulated by leptin and metabolic rate, regulated by thyroid hormone[18].Thyroid hormones play a very important role in controlling the body's metabolism, the rate at which the body uses energy, bystimulating divers metabolic activates most tissue, leading to an increase in basal metabolic rateone consequence of this activity is to increase body heat production[19]. So thyroid hormones with leptin might be involved in the adaptive thermo genesis[20].

Subjects and Method:A case control study was conducted at the center of diabetes management and research between 1st of December 2019 to the 15th of May 2020. The study include 100 subjects, divided into three groups: group 1: included 20 (11 male and 9 female) apparently healthy individuals whose body mass index (BMI) below 25 kg/m^2, age range 30-60 years, group 2: included 20 (8 male and 12 female) healthy individuals whose BMI equal or above to 25 kg/m^2, age range 32-60 years, and group 3: included 60 (28 male and 32 female) newly diagnosed diabetic patients whose BMI equal or above to 25 kg/m^2, age range 35-66 years.From all participants, a fasting blood sample was taken for measurement of fasting plasma glucose (FPG), glycated hemoglobin (HbA1c), lipid profile, serum leptin, thyroid hormones, thyroid stimulating hormone (TSH) and fasting insulin. Insulin resistance (IR), BMI and atherogenic index (AI) were calculated according to special equations.

Statistical Analysis: The data obtained in the current study was analyzed using statistical package for social science (SPSS) program version 26. Different descriptive statistical method were used to summarize and tabulate the data. ANOVA test were used to compare the mean difference of all parameters between the three groups. Duncan test were used to determine the non-homogenous group if the result of ANOVA test was significant. Furthermore independent 2 samples student t-test were used to compare the difference between each 2 groups.

Results:

Demographic and clinical characteristics of all participants in this study shown in table 1:

Table (1): Demographic and clinical characteristics of the participants.

Characteristics	Group 1 (no. = 20)	Group 2 (no. = 20)	Group 3 (no. = 60)
Age Range (Mean± SD)	30-60(44.0±8.3)	32-60(45.0±7.0)	35-66(47.5 ±7.4)
Male no. (%)	11 (55)	8 (40)	28 (46.6)
Female no. (%)	9 (45)	12 (60)	32 (53.3)

Discussion

The present study provides a wide view on biochemical features in blood of type 2 diabetic patients and non diabetic obese. Serum leptin determination and its correlation with other biochemical parameters were targeted in those groups. The mean age of type 2 diabetic patients who were participated in our study was (47.5 ±7.4) years coincides with the fact that type 2 diabetes mellitus usually develops after age 40 years[21].

In our study it was found that mean serum leptin level was higher in obese (33.8 ± 29.0) and diabetic groups (20.6 ± 12.5) than non-obese group (2.9 ± 1.2) and correlates positively and strongly with BMI ($p< 0.001$) in the three groups which is an important index of obesity. This finding was agreed with a study conducted in Baghdad, Iraq 2009,which compared a two groups, obese and non obese participants, and showed a positive correlation between leptin and BMI ($P<0.01$) [22]. However, lower levels of leptin were observed in diabetes in study done to investigate the hormone resistance in diabetes and obesity[23]. This implies that the role of leptin in type 2 diabetes is controversial and still needs further investigation.

The mean HbA1c of 8.97 % observed in T2DM patients and there was a significant difference in HbA1c levels between the non diabetic groups and the diabetic group both had (p value <0.000). However we could not find, a significant difference in HbA1c levels between non diabetic groups, the obese and non obese patients, although it was obviously lower in the non obese patients implying a better glycemic status in such patients. This results similar to the result of case control study conducted in Iraq 2008[24].

A highly significant difference in insulin resistance (HOMA) was observed in diabetic group as compared to non obese group, which was expected because of the increased level of fasting plasma glucose and high level of serum insulin in diabetic patients, and there was a highly significant difference in insulin resistance (HOMA) was observed in obese group as compared to non obese group which was expected due to high level of serum insulin in obese group which indicate the presence of insulin resistance in this group. The result show a significant difference in insulin resistance (p-value < 0.05) between diabetic and obese group.

The results of serum lipid profile in our study show that, cholesterol, triglycerides and LDL-C levels were significantly increased in diabetic patients and obese controls when compared to non obese controls whereas HDL-C level was significantly decreased in diabetics. Our study revealed no significant correlation between leptin and Total cholestrole, HDL-c, LDL-c, triglycerides and atherogenic index in all studied groups. These findings are in agreement with Assal et al.[25] and Al-Shoumer et al.[26], who showed no significant correlation between leptin and the lipid profile in diabetic patients, obese non diabetic and non obese non diabetic groups.

Obesity as a cause of insulin resistance may play a role in thyroid dysfunction. There is evidence that low free T4 is associated with insulin resistance[27]. Solanki et al[28] reported significant correlation between BMI and TSH in healthy adults and BMI was negatively associated with serum fT4 but had no association with serum fT3. There is a positive association between TSH and obesity (BMI) which is similar to the result shown in Chinese study[29] where they explain these result as

an alterations in thyroid hormones activity or as a result of an alteration in the regulation of the hypothalamic-pituitary-thyroid axis, and our results agreed with a study conducted in Saudi 2017[30]. In this study, the comparison of thyroid function between diabetic and the non obese group show a highly significant differences in TSH and fT4 (p value < 0.01) and a (p value < 0.05) for fT3. There is also a highly significant differences in TSH between obese and diabetic groups. These result agreed with a case control study conducted in the Diabetes and Endocrine Center at Al-Husain Teaching Hospital, AL-Muthanna, Iraq 2015[31]. Our results show a positive correlation between the level of leptin and TSH in both diabetic and obese group while showing a negative correlation in non obese group and it is reverse for both fT3 and fT4.

We conclude that there was increase in the BMI is associated with increase in serum leptin level. Patients with type 2 diabetes had significantly lower serum leptin compared with healthy subjects of the same BMI. Healthy subjects complaining from obesity are at a high risk of developing diabetes in the future concluded from the facts that their HbA1c and IR was significantly higher compared with thin healthy control and highly significant difference in fasting serum insulin level. TSH show high level and a low levels of thyroid hormones in diabetic and obese participant compare with that of non obese group, i.e. TSH levels correlate with insulin resistance in obese patients.

Author's Contributions: Both authors played a key role in carrying out the study to conductive outcome. All authors were involved in the study design,data analysis,data collection,implementation of research and in the critical revision the final approval of manuscript.

Conflict of Interest: the authors declare that there are no conflict of interest.

Abstract

Background: Thoracic epidural anesthesia for LC is a satisfactory alternative technique in selected cases, therefore aim of current study was compare the deference between using of bupivacaine 0.5% at one and bupivacaine 0.5%. With sodium Bicarbonate 8.4 %. The differences we deal with there are onset of action. Duration of action, Potency, and the occurrence of complications. We report the sex, Age and smoking to see we these factors can affecting the study ornot.

Patients and Method: The sample contain 2 groups of patient each group involved 20 patent with deferent age and sex. Group A receive Bupivacaine 0.5% 12ml alone for thoracic epidural anesthesia at level of T6 for laparoscopic. Cholecystectomy while ingroup B, we give Bupivacaine 0.5% 12ml with sodium bicarbonate 8.4 % 5ml (420mg) for the same operation at the same level of injection. In both groups we put the epidural catheter for addition of more dose of Bupivacaine and the mixture if the action of drug is finish and for the postoperative pain management after the operation.

Keywords: *Bupivacaine;sodium bicarbonate; thoracic epidural anesthesia; laparoscopic cholecystectomy.*

Introduction

Traditionally laparoscopic choli cystectomy is done under general anesthesia, but recently there is a growing interest to get it conducted under central neuraxial blockade[1,2]. We conducted a clinical study comprising bupivacaine 0.5% alone or a combination of bupivacaine and sodium bicarbonate (420 mg/5ml of 8.4% sol) in thoracic epidural anesthesia for laparoscopic cholecystectomy (LC) the aim is to see whether there is deference in onset of actin, Potency, Duration of action and occurrence of any complication during procedure.

Epidural anesthesia was considered safe for laparoscopic cholecystectomy without associated respiratory depression as the respiratory control mechanism remains intact to allow the patients to adjust their minute ventilation. Moreover, the respiratory changes are less evident in awaken patients under regional anesthesia and patients maintain an unchanged end tidal carbon dioxide[3].

The benefit of TEA not only for patient with respiratory diseases but also for management of postoperative pain where we can connect the epidural catheter with patient control analgesia (PCA)[4].

Patients and Method

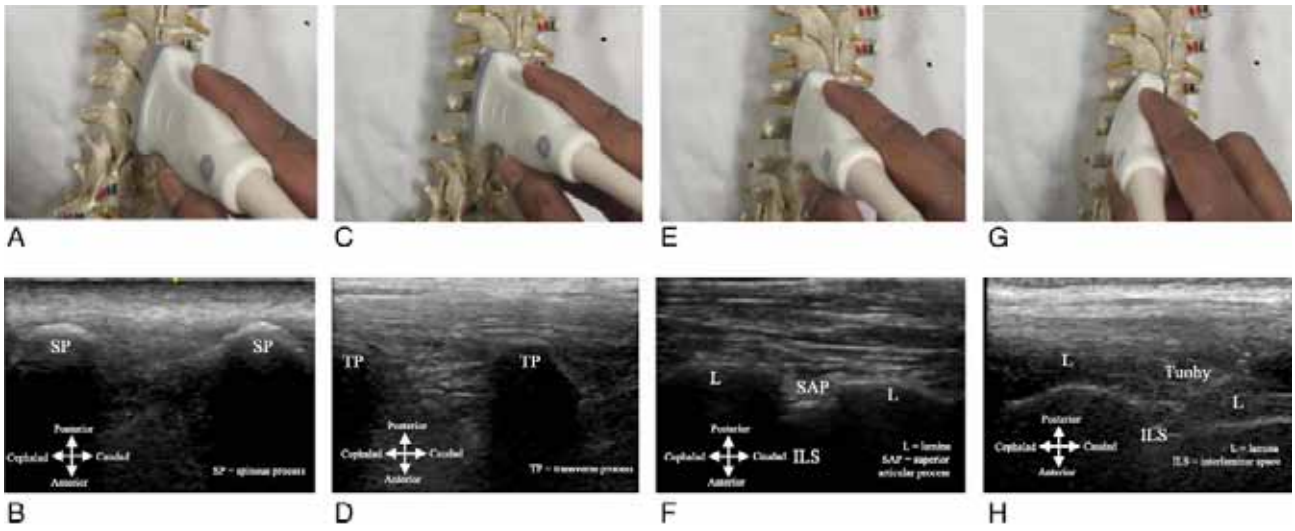
The epidural anesthesia can be done by two method as traditional or classic method and by Ultrasonograplaly.

A. Traditional method

Preparations: An epidural must be performed in a work area that is equipped for airway management and resuscitation. Facilities for monitoring blood pressure and heart rate must be available. It is advisable to obtain informed consent prior to performing an epidural in the same way a before any other invasive procedure. Laboratory assessment are necessary like fasting blood sugar. Blood urea and creatinine, coagulopathy (PT, PTT, BT, INR), also history of anticoagulant therapy. ECG and chest x-ray should be done as routine tests. I.v.line should be inserted before procedure with loading of circulation with 500ml crystalloid fluid.

Procedure: Patient put in sitting or lateral position. Good sterilization of the site of injection; we anesthetized the site of injection by 3ml bupivacaine or xylocaine with syringe 18g needle. After 2min., we introduce the touhyneedle gently till we reach the ligamentum flavum where we fell a resistance. At this point, we should apply the loss of resistance technique either by air or by saline in syringe. Once the loss of resistance feel, the advance of touhy needle should be stopped. Then the epidural catheter can be inserted in appropriate distance while the touhy needle removed gently. Then the catheter fixed properly. After that the anesthesia can be begine by pushing of anesthetic agent. We start with testing dose (3ml) and waiting for 3min. and monitor the patent for any signs or symptoms of allergy from the anesthetic agent can be given.

Epidural anesthesia by ultrasound guide: All the preparations and laboratory tests are the same including the positioning and sterilization of the patient. Here, the insertion of the touhy needle will done under the direct vision of the ultrasonography which make the procedure easier, safe and less time consuming. Ultrasound imaging was completed using a GE LOGIQe 9L linear probe, 8 to 10 MHz. After the determining of the thoracic level using us technique of locating the 12th rib and tracking cephalad, us probe was placed in the longitudinal plane on the midline of the patient back to visualize the thoracic spinous processes. As is our standard of care, the T8-T9 interspace was most commonly chosen for placement of the thoracic epidural. Although discretion was allowed for variations in surgical incision site and technique. Once the appropriate interspace was localized, a para- median sagittal transverse process view was obtained by moving the probe 2cm lateral to visualize the corresponding transverse processes. Which appear as successive hyperechoic domes. Maintaining the Para- median sagittal orientation, The probe was moved 1cm medial for the articular process view. Where the superior articular process of the inferior vertebrae could be seen. The parameter sagittal oblique view was obtained by turning the cephalad and of the probe medially with a concurrent medial tilt until the superior or articular process of the targeted interlaminar space could no longer visualized. Further tilting motions of the probe were made to optimize the gap in between the laminae which represent to note that with our us probe and technique the epidural space was not visualized. This is a critical point especially at a depth greater than 4 cm. Once the targeted interlaminar space was identified the intended needle entery site at the skin was infiltered with 2% lidocaine. A 17 gaugetouhy needle was inserted from the caudal end of the probe and advance under real time us assistance using an in- plane approach to the interlaminar space until the tip of the touhy needle was safely directed to the distance of the previously visualized superior articular process of the inferior lamina. No attempt was made to deliberately contact the lamina with the needle. Once the touhy was visually localized in the previously mention position. The needle was advance until the epidural space was identified with LOR to air because the needle tip could not visualize at all time under us at these depths. The epidural catheter was advance such that 4cm remained in the epidural space.



Finger 1: For the spinous process view of the thoracic spine, the US probe should be orientated longitudinally along the midline of the thoracic spine (A) so that successive spinous processes can be seen on US (B). For the paramedian sagittal transverse process view, the US probe is moved 2 to 3 cm lateral from the spinous process (C). Successive hyperechoic domes with fingerlike shadowing or "trident sign" represent the transverse processes (D). For the paramedian sagittal articular process view, the probe is moved 1 cmmedially (E). The superior articular process of the inferior vertebra can be seen along with the corresponding laminae (F). The paramedian sagittal oblique view can be obtained by turning the cephalad end of the probe medially with a slight medial tilt (G) to optimize the view of the interlaminar space seen in (H), where the Tuohy needle is advanced under direct visualization

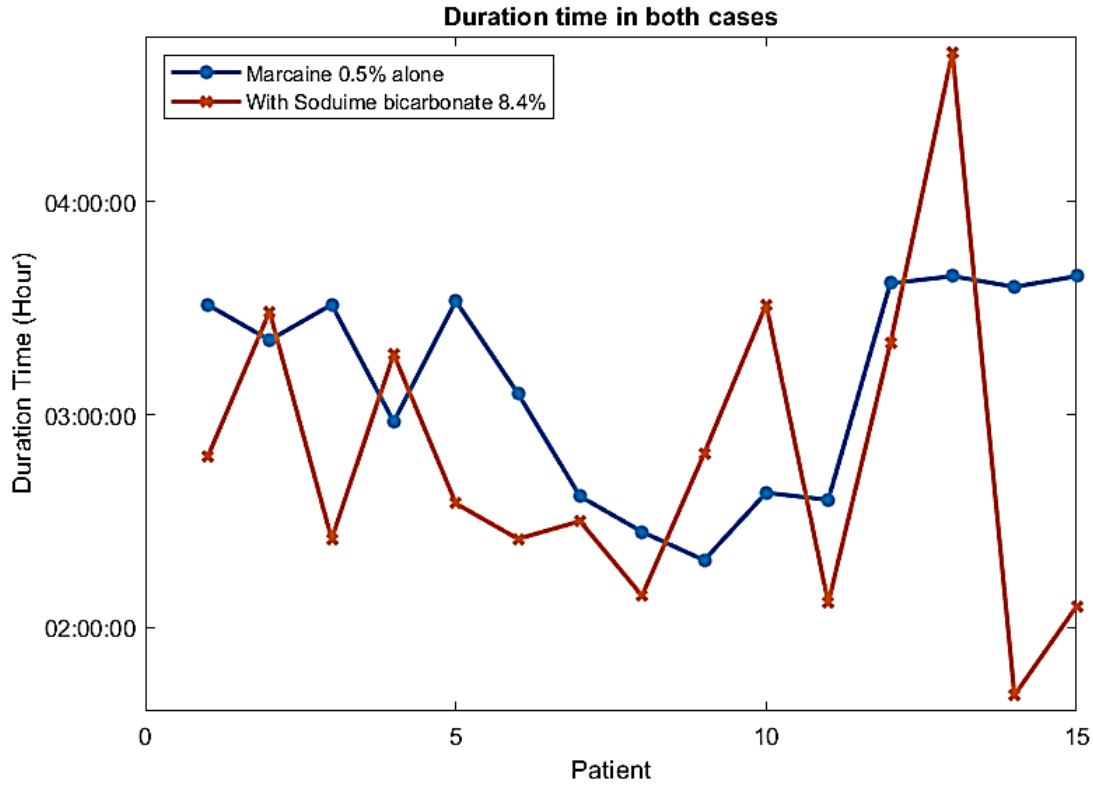

Fig 3: The Duration time in both groups

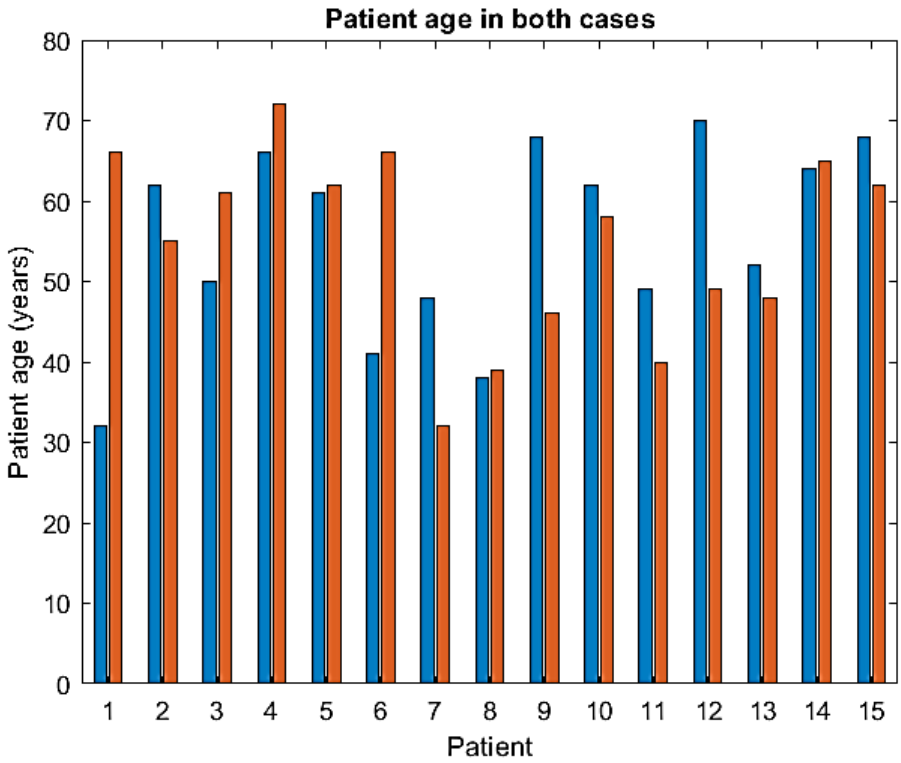

Fig 4: The Patient Age in both groups

Discussion

In this study, we take two groups of patients with different ages and sex contain 20 patients for each group. We did thoracic epidural anesthesia with ultrasound guide at T6 level for Laparoscopic cholecystectomy in group A we used Marcaine 0.5 % 12 ml only while in group B we used Marcaine 0.5 % 12 ml plus sodium bicarbonate 8.4 % 5 ml. we compare 2groups for the onset of anesthesia, Duration of action, Potency of anesthesia and occurrence of complications. In fact,For all patient we used thoracic epidural anesthesia at T6 level as anesthesia during operation and analgesia for postoperative pain. We didn't add general anesthesia for any patient but we used the adjuvant drugs for decrease the anxiety of patients like fentany l 50 mg plus midazolam 3 mg i.v. All the operations are lasting 40 min to 1.10 hr. for the surgical procedure. Ghodki *et al*. gave intrathecal clonidine besides bupivacaine in spinal anesthesia for LC which provided prolonged postoperative analgesia and sedation besides relief of shoulder pain[5].whilst Rademaker *et al*. used continuous thoracic epidural for LC and found that metabolic endocrine response was attenuated and postoperative pain was also less[6].

Conclusion

During this study, we find that there was no difference in onset of anesthesia potency of anesthesia and duration of action of agent between group A and B. in fact there was a very little shortness in onset of anesthesia which is not significant. In addition to that, no complications are reported during this study in both groups.

Abstract

Background: Bullying among schoolchildren is certainly a very old phenomenon. The fact that some children are frequently and systematically harassed and attacked by other children has been described in literary works, and many adults have personal experience of it from their own school days.

Subjects and Method: This cross-sectional study carried out on randomly selected 450 elementary schools' students in 5th and 6th classes 222 males, 228 females in holly Karbala city, province in academic year 2015 - 2016. Data were collected by using a standardized questionnaire.

Result: Overall prevalence rate of peer bullying was 33.8% and the prevalence of victims was 25.3%. Results of current study show that there is statistical significant association between bullying and gender, the bullying is more common in males students 38.7% than female 28.89%, while 19.8 % males, 30.7% females were victims of this behavior, this difference is statically significant also the study revealed that bulling was prevalent in poor families.

Conclusion: Peerbulling is highly prevalent in primary schools in holly Karbala city, Iraq, compared to many countries, there were positive association between bulling and male students,poverty, low school achievement.

Keywords: *Peer bullying; old phenomenon; primary schools' children; Karbala center.*

Introduction

Bullying among schoolchildren is certainly a very old phenomenon. The fact that some children are frequently and systematically harassed and attacked by other children has been described in literary works, and many adults have personal experience of it from their own school days[(1).]

Evidence suggests that bullying has acute consequences that range from suicide, murder and absenteeism at school to medical conditions such as fits, faints, vomiting, headaches and long-term psychological problems such as anxiety, depression, loneliness and hysteria[(2).]

Given that bullying in schools is a prevalent and concerning issue, there has been an apparent increase in bullying studies at the national and international levels[(3).]

The accurate assessment of bullying provides an opportunity to examine the dimensions of the construct, seriousness of the bullying in schools, and utilization of precise intervention strategies based on that) information[(4)].

Bullying is one type of violence that threatens a youth's well-being in schools and neighborhoods[(5)]. Bullying may inflict harm or distress on the targeted youth (including physical, psychological, social, or educational harm[(6)]. A young person can be a perpetrator, a victim, or both (also known as "bully/victim")[(7).]

Youth who bully others are at increased risk for substance use, academic problems, and violence later in adolescence and adulthood[(8).]

Compared to youth who only bully, or who are only victims, bully-victims suffer the most serious

consequences and are at greater risk for both mental health and behavior problems[9].

Objectives: To measure prevalence of bullying among samples of students in primary schools in fifth and sixth class levels and to evaluate the relationship between direct bullying and different variables (gender, grade level, socioeconomic status, parental status, ...).

Research on bullying was began in Europe in 1970 lead by Dan Olweus, Norwegian researcher began to study this matter[10].

Meaning there is imbalance of power between perpetrators (bullies) and victims.

($ subjects and merods) [12 & 13].

Subjects and Method

This study was carried out in the Holly Karbala city Centre, in which there are 177 elementary schools this is school - based cross - sectional study. duration continued from mid of January 2016 to the end of July 2016, the work of data collection took 4 days during the week. Out of (177)primary school in Karbala city, 16 primery school have been selected by simple random sampling method using computer available in planning department in Karbala Director of Education From these 16 primary schools, the students of the 5th and 6th classes have been selected . Out of these classes study sample have been selected by using systemic sampling method student. The total number in 5th and 6th classes in these schools which is C 2162), the sample size is 450.

Questionnaire: A structured questionnaire was prepared by researcher that was adopted from a questionnaire of Dan - Olweus standardized questionnaire developed as a part of bullying survey for students in 2006[14] zce's go (Cronbach alpha interior consistency of bully scale 0.88 and for victimization scale 0.87 for this questionnaire).

The questionnaire translated to Arabic by an expert with minor modification . the questionnaire was designed to measure several aspects of bullying behavior in last 2 months .

Several sub scales were used in the questionnaire: 1. It contain 27 items about direct bullying (physical, verbal), victims. 2. Questions about gender, class level, order of birth. 3. Questions about academic level (average, below average, good) using grade point average as indicator of academic achievement. Most of primary, middle, high school in Iraq grade out of 100 percent with a passing 50 percent so the grade point average is out of 100 as described below[15].

Grade percentage: excellent 90 –100;very good 80 –89;good 70 – 79;acceptable 50 – 59;weak 0 – 40

Score Instruction: Never occur = 0;Once or twice = 1;Two or three times in a month = 2;One time in a week = 4;Six items about victimization from 12 – 17;Three items for physical victimization 19, 21, 22;Two items for verbal victimization 20,23;Statistical analysis was carried out using SPSS version 22.

Results

A total of 450 primary school students were enrolled in this study, of them 230 (51.1%) of 5th class and the remaining 220 (48.9%) of the 6th class moreover, males were 222 (49.3%) while females were 228 (50.7%). Other characteristics of the studied group are shown in (Table 1).

Table 1. Frequency distribution of students according to socio-demographic characteristics (N = 450)

Variable		Frequency	%
Class level	5th	230	51.1%
	6th	220	48.90%
Gender	Male	222	49.30%
	Female	228	50.70%
Order of birth	First	109	24.20%
	Second	122	27.1%
	Third or more	219	48.7%

Variable		Frequency	%
Student's father status	Alive	422	93.80%
	Dead	28	6.20%
Student's parents live together	Yes	395	87.8%
	No	55	12.20%
Family income	Not enough	292	64.90%
	Enough	158	35.1%
Student's school performance	Good	152	33.8%
	Acceptable	224	49.8%
	Weak	74	16.4%
Father encourage this behavior	Yes	206	45.8%
	No	244	54.2%
Mother encourage this behavior	Yes	195	43.3%
	No	255	56.7%

Table 2. Frequency distribution of the types of bullying

Bullying type	Frequency	%
Verbal Bullying only	69	45.4
Physical Bullying only	45	29.6
Both types	38	25.0
Total	152	100.0

Table 3. Frequency distribution of the types of victim

Victim type	Frequency	%
Verbal	56	49.1
Physical	35	30.7
Both types	23	20.2
Total	114	100.0

Discussion

In this analysis of 450 elementary school students the results of study demonstrated that 33.8% of elementary level students reported that they were bullied another students and 25.3% of students were victims during the last two months . It is lower than the study in north Africa countries in 2008 found that 60 % of students in Egypt and one third of students in Libya, morocco, and Tunisia reported having been bullied(11) . This rate is considerably higher when compere to other studies in other contraries, for instance in Canada in 2010 an average of 26000 were surveyed the percentage was 12 % of students reported being bullies once or times in last two months and percentage of victims was 22 %[16].

In another study in Turkey in 2009 the ratio estimated of victimization was 15 - 20 % and percentage of bullies was 22%[17]. In this study according to the comparisons made between gender variables, it was understood that the male students bullying behaviour" bullies" were higher than in the female students . Females were found to be exposed to be victims more than males . This finding is consistence with other studies carried out in different countries[18 & 19].

Even in some culture environments, male students' aggressive behaviour are appreciated by society and this finding agree with other study. This variable was significantly associated with being a victim status; was being a female students.[20]

In current study, there were insignificantly associated with bullying, may be the students were nearly had the same age . so,there was no relationship between bullying and order of birth . While in some studies the order of birth play role in developing bullies children [21].

Students who saw themselves as members of low socioeconomic families tended to exhibit more bullying behavior than those with high socioeconomic class families . Bullying was significantly associated with not enough family income. This finding is similar to the finding of other studies .based up on various research findings, the present study claimed that, if their needs for love, care, respect and social interaction are not met, students from low socioeconomic class families tend to develop more bulling attitudes in order to attract attention and to prove their identity[22].

The other significant factor associated with bullying was student's school performance, where it had been significantly found that bullying was inversely associated with the student performance, the lower proportion of bullying was reported among the students with good school performance, (19.1%), followed by those with acceptable level, (32.1%) while the higher proportion was reported among those with weak performance, (P< 0.001). The students with weak school performance were more likely to be victims than other students.

This assesses the educational harm experienced as a result of being bullied during a specified time period. Educational harm is defined as decreases in academic performance (e.g., lower grades), diminished school engagement (e.g., poor attendance or dropping out of school), missed educational opportunities (e.g., the youth is scared to go to tutoring program or class), negative perceptions of school or other educational activities (e.g., the youth is afraid to go to school, hates school, or does not trust adults in the school), or decreased participation in school-sponsored extracurricular activities such as band, team sports, theatre, and school clubs.

The school yard was the most frequent site for bullying to occur, followed by class room, this result is like other study[15].

This could be explained that the bullies can do their aggressive behavior freely, where three is no teachers or other adults that may stop them. Father encourage this behavior and mother encourage this behavior were insignificantly associated with bullying, these variables, (P>0.05), Students of parents who live together were less likely to be bullies compared to those of separated parents, 29.6% vs. 63.6%, respectively, (P< 0.001). student whose father was dead, student whose father not live together, are likely to be victims.

Conclusions

1. Peer bullying is highly prevalent in primary schools in Holly Karbala city/Iraq compared to other countries and it lower than north Africa countries.
2. Peer bullying was higher in males than females' students and Peer victimization was higher in females' students than males' students. So, Peer bulling and victimization were significantly high among students from families with low socioeconomic class and separated parents and student whose father was dead, student whose parents not live together, exhibition to be victims. And not enough family income was the more predictor factor for bullying.

Abstract

Objective: The aim of study to find out the prevalence of cancer in Al muthanna province, the most common type of cancer, the danger age group, gender and the site of malignancyin the body.

Methodology: The study sample about (100) case was taken from cancer patients from laboratory unit in al Hussein teaching hospital from July 2018 to September 2019 . the study design was a quantitative descriptive design . the data collection taken by the researchers was self report dichomitus, the method of self report was conceder as on type of data collections by using phrases occur or not occur in all types of cancer .

Result and Conclusion: Indicated that the age between (51-61) years was have more percentage of 29.5, female affected by cancer more than male and rural area affected by cancer is more than urban.

Recommendation: Further research do about cancer prevalence and the risk factor in the most common area in province .

Keywords: *Cancer, types, histopathology, prevalence, Al muthana.*

Introduction

Cancer is one of the most leading causes of morbidity and mortality in worldwide, it's also the second cause of death in the world, and was responsible for 8.8 million deaths in 2015. The most common organ affected by cancers include: Breast, lung, Liver, Colorectal,and Stomach. nearly 1 in 6 deaths is due to cancer. Approximately 70% of deaths from cancer occur commonly in low- and middle-income countries and Around one third of deaths from cancer are due to behavioral and dietary risks as low fruit and vegetable intake, lack of physical activity, tobacco use, and alcohol use . Between 30–50% of cancers may be prevented by decrease risk factors and implementing existing evidence-based prevention strategies. The cancer burden can also reduced by early detection of cancer in the body and management of patients who have cancer. Many cancers have a high chance of cure if diagnosed in early stage of disease and treated adequately.[1]

In Iraq according to the Ministry of Health statistics in 2016 cancer is always considered a significant health problem and the second leading cause of death. The total number of cases of cancer during 2015 was 25,269 and male to female ratio 0.8:1. The most affected age group was 70 +years, and the incidence increased with age .

The top ten cancer are breast (19.1%), bronchus & lung (8.1%), leukemia (6.3%), brain & other central

nervous system (CNS) (6.1%), colorectal (5.7%), urinary bladder (5.1%), Non-Hodgkin lymphomas (4.3%), thyroid gland (3.8%), skin (3.2%), and stomach (3.2%). The highest incidence of cancer in males was bronchus & lung cancer (6.7/100,000 males population), while in females was breast cancer (25.8/100,000 females population). The incidence of breast, bronchus & lung, brain & other CNS, colorectal, thyroid gland, and stomach cancer increased for the last 5 years (2011-2015). But the incidence of leukemia, lymphoma, and urinary bladder cancer decreased for the last 5 years (2011- 2015). While the incidence of skin cancer not change.[2]

Muthana province have cancer case by 11.9% of the area of Iraq.[3] So it most be assess for prevalence of cancer and most receiving a significant attention in Iraq as a major health problem both in terms of incidence and mortality[4,5,6].

The colorectal cancer is the third common cancer affect male in the world and second leading death in western world,it account 9.4% in male and 10.1% in female.[7]

Materials and Method

Purposive(non probability) sample was taken from cancer patients from laboratory unit in al Hussein teaching hospital from July 2018 to September 2019 . the study design was a quantitative descriptive design. (100) patient have cancer in different types.

The data collection taken by the researchers was self report dichomitus, the method of self report was conceder as on type of data collections by using phrases occur or not occur in all types of cancer .

Four questions contain the following : Age, Gender, Address and type of cancer take from patient have histopathological investigations by having malignant diseases .

Result and Discussion

Table (1) Distribution of the Study Samples by Socio- Demographic Characteristics

Items	Sub-groups	Study group Total = 95	
		Frequency	Percentage
Age/Years	21-30	6	6.3
	31-40	18	18.9
	41-50	19	20.0
	51-60	28	29.5
	61-70	13	13.7
	71>=	11	11.6
	Mean = 52.63	**Standard deviation = ± 14.23**	
Gender	Male	36	37.9
	Female	59	62.1
Residency	Urban	36	37.9
	Rural	59	62.1

Table (1): show that variable age group was affect by cancer and the age between 51- 60 were mostly affected, this finding is identical to cancer research in UK, About 9 in 10 cancer case in UK are in age 50 or over and this is true for most types of cancer .this due to cell damage over time that can some time lead to cancer, Also this study identical with study approved by the cancer .net editorial board in 2019 that greatest risk age was 60 or older about 60% of people who have cancer . Also Mary C. et al say that cancer consider an age –related disease because the incidence of most cancer increase with age.[8]

Also this table show that the female more affected by cancer than male mainly by breast cancer this result is

identical to study done in USA in which they show that Breast cancer is the most common cancer in American women,But every woman should know about the risks for breast cancer and what they can do to help lower their risk.[9,10,11]

Table (2) Distribution of the Study Samples by type of cancer

Items	Sub-groups	Study group Total = 95	
		Frequency	Percentage
Cancer type	Breast cancer	40	42.1
	Prostate	7	7.4
	Brain	3	3.2
	rectum	2	2.1
	Kidney	4	4.2
	Lung	6	6.3
	Thyroid	5	5.3
	Nose	1	1.1
	Larynx	2	2.1
	Bone	4	4.2
	Ovary	2	2.1
	Skin	1	1.1
	Urinary bladder	4	4.2
	Blood	1	1.1
	Uterus	4	4.2
	Pancreas	1	1.1
	Lymph node	2	2.1
	Colon	4	4.2
	Stomach	1	1.1
	Gall bladder	1	1.1
	Total	95	100

Table (2): Show that breast cancer is more common type in Al-Muthanna government this result was identical to The American Cancer Society result that find **Women at high risk for breast cancer** is due to their family history, a genetic mutation, or other risk factors .

The American Cancer Society recommends the following for women at average risk for breast cancer: **Women ages 40 to 44** should have the choice to start yearly breast cancer screening with a mammogram (x-ray of the breast) if they wish to do so. **Women age 45 to 54** should get a mammogram every year. **Women 55 and older** can switch to a mammogram every 2 years, or can continue yearly screening.

Screening should continue as long as a woman is in good health and is expected to live at least 10 more years.[12,13]

There are also increase of frequency of prostate cancer in male in Al-Muthana government .this identical to study done by Husain HY, Al-Alwacahi SF that shows Prostate cancer is the second most frequent malignancy (after lung cancer) in men worldwide, counting 1,276,106 new cases and causing 358,989 deaths (3.8% of all deaths caused by cancer in men) in 2018[14,15]. The incidence and mortality of prostate cancer worldwide correlate with increasing age,they shows that Diet and physical activity play an important role in prostate cancer development

and progression. Dietary factors are mainly associated with the observed worldwide and ethnic differences in the incidence rates of prostate cancer.[16,17,18,19,20] The total number of cases of cancer during 2015 was 25,269 and male to female ratio 0.8:1. The most affected age group was 70 +years, and the incidence increased with age bronchus & lung (8.1%), thyroid gland (3.8%),%), colorectal (5.7%), while in females was breast cancer (25.8/100,000 females population). The incidence of breast, bronchus & lung, brain & other CNS, colorectal, thyroid gland, and stomach cancer increased for the last 5 years (2011-2015).this is correlate to this study while in the study done by Environmental Statistics in Iraq Report 2009 the incidence of leukemia, lymphoma, and urinary bladder cancer decreased for the last 5 years (2011- 2015) this is also identical to this study done in Al –Mothana government .

Table (3): The association and correlation between type of cancer and Socio- Demographic Characteristics:

Items	Sub-groups	Type of cancer																				
		Breast cancer	Prostate	brain	rectum	Kidney	lung	thyroid	Nose	larynx	bone	ovary	skin	Urinary bladder bladder	blood	uterus	pancreas	Lymph node	colon	stomach	Gall bladder	total

Table (3): show that significant association between age and type of cancer the common age group was between (51-60) which is breast cancer . this study identical to study done by the National Cancer Institute (NCI) which found that Breast cancer is most common cancer affect females over the age of 50 years so doctors most often diagnose breast cancer in females aged 55-64 years. The NCI Based on data from 2012-2016 saw that the median age of diagnosis in females with breast cancer was 62 years old. The NCI also report that of the 437,722 females that doctors diagnosed breast cancer in between 2012 and 2016:

- 1.9% were aged 20–34 years
- 8.4% were aged 35–44 years
- 20.1% were aged 44–55 years

- 25.6% were aged 55–64 years
- 24.8% were aged 65–74 years
- 13.7% were aged 75–84 years
- 5.6% were aged 84 years+
- Medically reviewed by Yamini Ranchod, PhD, MS on July 3, 2019 — Written by Lana Burgess.[21]

This table show that there is significant association between age and gender,cancer is more affect female than male, from total 95 case was taken in AL-Hussein teaching hospital, about 59 female was affect by cancer this study is identical to study done by Moynihan C. that show female is more affect than male .[22] Also there is no significant association between the site of case affected by cancer and the type of cancer . there is increase incidence of cancer in rural area than in urban area this study identical to study done by Meilleur A et.al in which. there is increase chance of having cancer in rural area,and The urban decline in incidence rate was greater than in rural populations (10.2% vs. 4.8%, respectively). Rural cancer disparities included higher rates of tobacco-associated, HPV-associated, lung and bronchus, cervical, and colorectal cancers across most population groups. Furthermore, HPV-associated cancer incidence rates increased in rural areas (APC = 0.724, $P < 0.05$), and decrease of preventive screening modalities for (e.g., colorectal and cervical cancers) were higher in rural compared with urban For many rural populations, cancer mortality is not decreasing; it is steady and, in some cases, rising. Several studies have documented persistently elevated cancer incidence and mortality in rural communities compared with urban areas[23-26]. also found, In 2010 to 2012, the highest rates of poverty and uninsured status in the nation were found in small rural counties and in large inner cities[27]. Also study done by Foutz J, Artiga S, Garfield R. 2017,large rural populations did not expand Medicaid, leaving millions of people still without health insurance[28]. Furthermore, there are documented barriers to health care access in rural communities. Many rural residents live in health care provider–shortage areas, may have fewer choices in care, and may need to travel long distances just to see a primary care physician. And rural area have lower rates of cancer screening, experience and lower quality cancer care [23-24]. Furthermore, numerous studies have identified higher rates of cancer-risk behaviors among rural residents, which can contribute to the elevated incidence rates of cancer . Higher rates of tobacco use and obesity in rural populations are consistently reported[29-33]. In addition, human papillomavirus (HPV) vaccination rates are lagging in rural areas, with lower rates associated with increasing rurality[34].Also it was seen that renal disease is the most common causing of malignancy in the kidney[35].

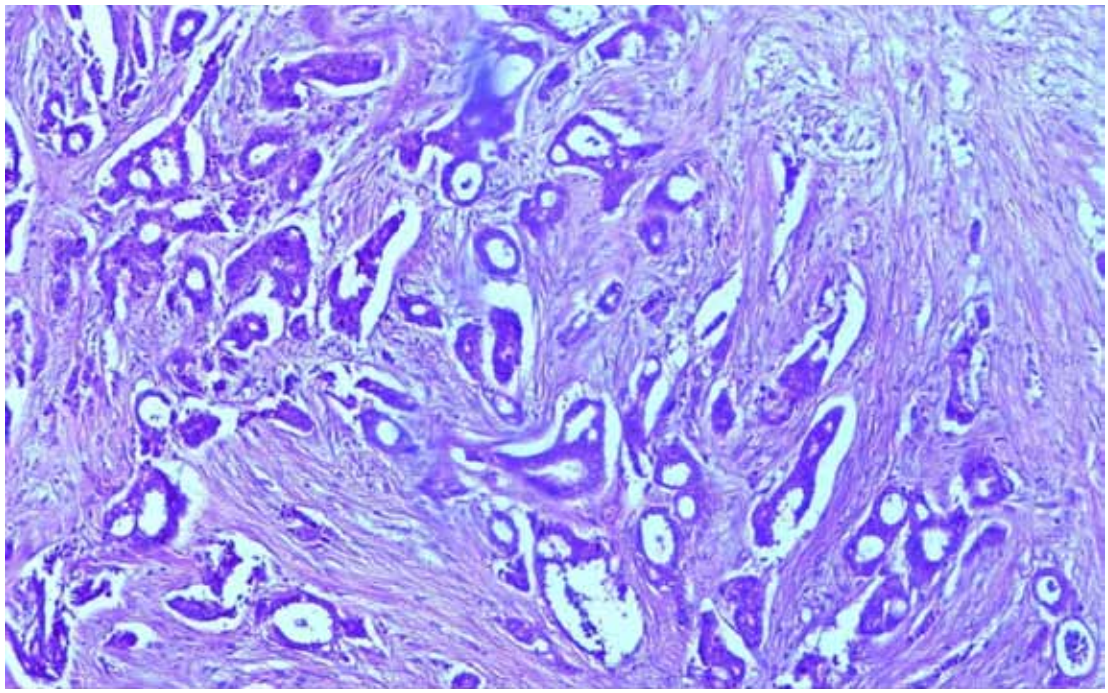

Figure (1): Invasive Ductal Carcinoma with H & E stain {40X} .

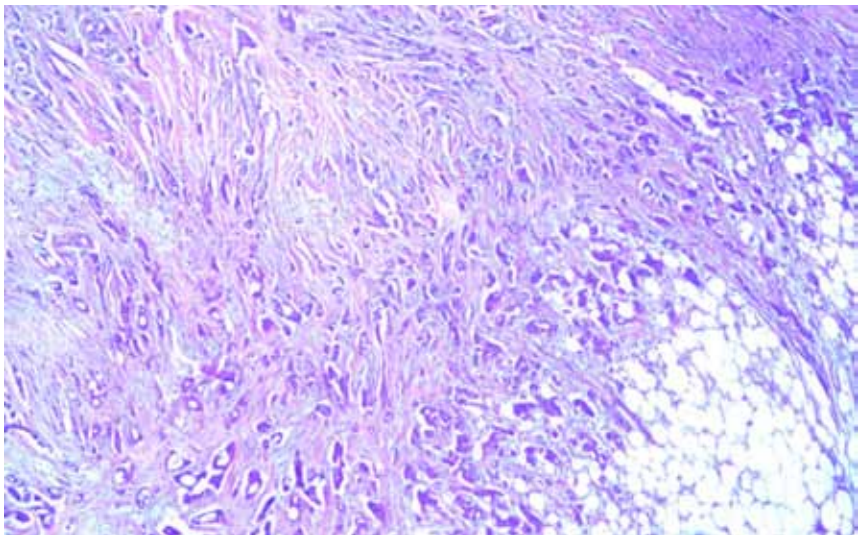

Figure (2): Invasive Ductal Carcinoma with H & E stain {40X}.

Figure (4): Prostatic Carcinoma with H & E stain {40X} .

Conclusion

1. Early Finding of cancer can help in rapid treatment and decrease the death rate between women so if breast cancer early diagnosed specially when it's very small, that not spread, might be easier to treat and can help to prevent deaths from the cancer.
2. Getting regular screening tests is the most reliable way to find cancer like breast cancer so it should be screened with MRI along with a mammogram.
3. Talk with a health care provider about risk for cancer and the best screening plan for it.

Recommendation:

1. Regular self -examination of female to the breast and the province must do educational program to the way for breast examination .
2. Improve personal habit like regular exercise, decrease fatty diet and eating more vegetable and fruit .
3. Give up smoking.
4. Regular check up to detect any abnormal growth in the body. **Women ages 40 to 44** should have the choice to start yearly breast cancer screening with a mammogram (x-ray of the breast) if they wish to do so. **Women age 45 to 54** should get a mammogram every year. **Women 55 and older** can switch to a mammogram every 2 years, or can continue yearly screening.
5. Further research do about cancer prevalence and the risk factor in the most common area in province .

Med., Al- Muthanaa University, [3]Assist. Prof., Department of Physiology, College of Medicine, Al- Muthanaa University, [4]Assist. Prof., Department of Internal and Preventive Medicine, Col. of Vet. Med.4

Abstract

The study was done on sixteen specimens including: eight Parrot and eight francolins of both sexes. The current study aims to discover the structures of proventiculi and ventriculi belonging to these birds specifically their histologic and histochemical textures. The anatomical studies revealed that stomach of both birds consists of: proventiculi & ventriculi. Histological exam was showed that the wall of proventiculus of the Parrot and francolin composed of four layers including: mucosa, submucosa, muscularis and serosa. The epithelia of proventiculi and venticulus were simple columnar cells for each bird.

The obtained means of thickness of layers of proventiculus and venticulus appear different between male and female of both birds.

For histochemical studies there were some different reaction of PAS- stain which were detailed in the results.

Keywords: *Francolin, Parrot, proventriculus, ventriculus, histochemistry.*

Introduction

Birds fall into about 8948 species and they are allocate din about 27 orders. Each order contains vast varying number of species. Passeriformes is considered the largest one as it possess about 5243 species. As containing one species only, Struthioniformes is considered the smallest. Francolin belongs to the order Anseriformes which possess five species(1). Black francolin belongs to Phasianidae family of pheasants and in the order Galliformes, the gallinaceous birds and it is called *Francolinus francolinus*. Comsidering it as a native bird to Asia, it was referred to as black partridge(2). The structure of the bird stomach was studied by different researchers including(3) in pigeon(4) in Japanese quail, (5) in red-capped cardinal, and(6) in partridge. Due to lack of information about the histological and histochemical structures of the stomach in francolin and Parrot, this study was accomplished to reveal it in both genders. The stomach of the birds is considered the most important part of the digestive system and it possess two parts; the proventiculus and venticulus or what is called gizzard. The latter contains the grit or gravel which has an importance with the aid of the muscles in facilitating the grinding up the food. To fulfil their requirements of energy, birds have a high rate of metabolism and they consume large quantities of food(7).

Materials and Method

Bird's Collection: Eight Parrot (*Psittacus erithacus*) and eight black francolin (*francolinus*) both sex were collected to perform the ongoing study. Birds were fetched from local markets at Al-Muthanaa and Al-Basra provinces.

Morphological Study: sodium pentobarbitone (140 mg/kg) was injected i.v. to make birds euthanized before accomplishing dissection[8]. After that, they were dissected by the use of a board for dissecting. Coelomic viscera were viewed by making an incision in the mid – line. By using a digital camera, stomach was photographed. A well illustrating figures were depended to exert the locations of these organs and their relationship. Debris and blood were washed out by the use of normal saline. Stomach was eviscerated by pressure to expel its content and then additional normal saline washing was carried out.

Histological Processing: neutral buffered formalin 10% was used to fix the specimens. Dehydration of the specimens was done by the use of ascending ethanol series to pass them in as a period of two hours each depending the concentrations (70, 80, 90, 95 and 100). Specimens were embedded in paraffin wax and then cleared with xylene till two hours. The prepared blocks were being sectioned on thickness of 6 μm and the below stains were used to perform staining: eosin – hematoxylin Mayer`s routine stain was applied to identify general characteristics, while collagen and smooth muscles were stained with the stain of Masson trichrome.

Histochemical Processing: Bouin`s solution was used to fix the specimens. Olympus microscope was used to exam and photograph the sections. PAS – alcian combined blue was used to determine the neutral mucin. Epithelial linings basement membranes of were illustrated by the use of PAS [9].

Results/Discussion

Morphological Finding: Figure (1) reveals that the stomach of parrot and francolin included like other birdsproventiculus and venticulus. Of these birds are domestic fowl[10], partridge[11], and Japanese quail. In contrast to that[12] has reported that there are three parts included in the stomach those are; proventiculus, venticulus and in addition to pylorus. Cranially to the esophagus and caudally to the gizzard, the proventiculus of the birds of our study situates as it is clear in (figure 1). Similar to the site in other birds like ostrich as was mentioned by [13] and [14], the proventiculus was vailed partially by hepatic left lobe. Figure (1) also reveals the venticulus of francolin takes a form of spindle and there is an amount of adipose tissue surround it. In other side, ventriculus of parrot appeared ovoid and muscular of a lesser size and there is a thick adipose tissue surround it. Might be due to the nature of food stuff of birds, the shape besides the size of the ventriculus could be differ as considering it as the muscular stomach part. In a line with other species like red –winged tinamou [6] and pigeon [14], the parrot ventriculus shape comes spherical as it I appear in (figure 1).

Histological Finding:

Proventriculus: Four layers were seen in the francolin proventriculus wall. These layers were mucosa, submucosa, muscularis and serosa layers as it is clear in figures 2, 4, and 5. [15] and [16] have reported the same structures of proventriculus in Struthiocamelus and Numidameleagris respectively. Figure 2 reveals that mucosa of francolin consists of folds that are branched and longitudinal and lined with an epithelium that is simple columnar in nature. Infiltrated with lymphocytes and blood vessels, a loose connective tissue was the structure belongs to the lamina properia as it is obvious in figures (2, 3, and 6). Also it was seen that there is a simple mucous tubular gland possessed within the lamina properia as it is obvious in figures (2, 4, and 5). The mean of thickness of this tunic was 2332 mm in male francolin, whereas in the female was higher up to 2521 mm.

In the parrot, the proventriculus characterized by folded mucosa with the presence of surface invaginations of regular intervals (Fig. 2,3). Similar to that in francolin, the lining epithelium was simple columnar and the lamina propria possessed simple tubular mucosal glands lined with the same epithelial lining, invested in loose connective tissue rich with blood vessels. The mean of thickness of this tunic was 1258 mm in male parrot, whereas in the female was higher up to 1431 mm.

The presence of simple columnar epithelial lining of the mucosa in the studied birds were similar to mucosal lining of the most avian species [17], guinea fowl [16] and pigeon [14]. Coming in line with what was reported by [18] and [19], the francolin`s and parrot`s mucosal glands were lined with simple cuboidal epithelium.Figures 2, 4, and 5 reveal that most thickness of the organ is occupied by

submucosa. What is being called proventriculus glands, were seen forming it.

The current findings of proventriculus glands were not in line with those of [20] and [21] who reported the lack of submucosal glands in the proventiculi belonging to chicks. Other findings relating to francolin were not in line with what reported by [22] and [23] who made their studies in aves and gray parrotwhere the submucosa contains tubular glands of proventriculus which are surrounded by a fibrous tissue and they are round in shape found in dense connective tissue while the findings of the researchers above have mentioned the glands to be pearl in shape lined up with columnar epithelium.

The mean of thickness of this tunic was 9860 μm and 9910 μm in male and female francolin, respectively. Whereas, in parrot the mean of thickness of this tunic was 13256 μm (in male) and 13588 μm (in female). The increased size of this tunic occupied most of the real area of the proventriculus wall containing numerous deep proventricular glands. This finding was disagreed with [25] in the jungle fowl who mentioned that the tunica submucosa was very thin in the proventricular wall or poorly developed in birds.

The mean diameter mean of these glands were 4355 μm in male francolin, whereas in the female was higher up to 4990 μm. The mean of diameters of the submucosal glands were 3922 μm and 3260 μm in the male and female parrot, respectively.

The thickness mean of this tunic was 920 μm in male francolin, whereas in the female was higher up to 1120μm and compared with parrot the mean of this tunic was 1120 μm and 1130 μm in male and female, respectively. Structures like adipose tissue, nerves, and blood vessels were the feature of serosa that was built up with loose connective tissue (Fig. 2,4,5). These findings were also observed by [12] in Japanese quail and [18] in Coot bird (Fulica atra). The mean of thickness of this tunic was 140 μm and 160μm in the male and female francolin, respectively. While the thickness mean of this tunic was 170 μm in male and female parrot.

The ventriculus (Gizzard): Figures (7, and 8) show the structure of this organ. Like other avian species, the structures of this organ was similar to those like red-capped cardinal and guinea fowl [5] and[16] respectively. The simple columnar cells lined the ventriculus in studied birds. Similar observations were recorded in other species for instance partridge [11], Red jungle fowl [25] and in the Blue and Yellow macaws [27]. This epithelium thrown into long folds in parrot (Fig. 7, 8) but not in francolin when they were parallel each to other and revealed between their bases the gastric pits which constitute more than the half of the mucosal thickness (Fig. 7). Mean of diameters belonging to these glands was 560.1 μm in the male francolin, while in the female was higher up to 722.3μm. The means of glands diameters were 344 μm and 321 μm in male and female parrots, respectively.

Muscularis mucosa appeared as circularly arranged smooth muscle bundles interrupted by the presence of mucosal glands in the lamina propria in francolin (Fig. 8), but in parrot appeared thinner layer of circularly arranged smooth muscle fibers separating the mucosa from the underlying submucosa. (Fig. 7).

The mean thickness of this tunic was 1910 μm and to 2100 μm in male and female francolin, whereas in the female, it was higher up to 2100 μm. In the parrot, the mean thickness of the mucosa was 2320 μm and 2540 μm in male and female, respectively.

Figures. 8, 9, and 10 reveal that the submucosa belonging to ventriculus is built up of vast dense connective tissue which is enriched with nerves and blood vessels. The mean of thickness of this tunic was 1280 μm in male francolin, whereas in the female was higher up to 1410 μm. But the thickness was higher in parrot in which the mean thickness of this tunica was 1820 μm and 1580 μm in male and female, respectively.

The above outcome agreed with those observed in the Red-Capped Cardinal (Paroaria gularis gularis)[8], in most avian[29] and in Rock dove (Columba livia)[30].

In the parrot, muscularis extera was formed by two thin layers of smooth muscle fibers. There were fine collagenous fibers distributed between the bundles of these smooth muscles (Fig. 7, and 9).

Three layers of muscles fibers existence in francolin were in line with the findings of[31] in the Urolоncha domestica[22] in the Fulica armillata (granivorous species) and[18] in the ventriculus of the red jungle fowl which is one of the seeds, fruits and insects eaters bird.

While the two layers of muscles fibers existence in the ventriculus of parrot was similar to the findings of[24],[25] and[32] in the organs belonging to red-capped cardinal, Coot bird and most avian species, respectively.

The thickness of this tunica was 11910µm 11840 µm in male and female francolin, respectively, but it was thinner in the parrotventriculus in which the mean thickness was 4410 µm and 4330 µm in male and female. The thickness of this layer in the ventriculus may concerned with mechanical grinding capability of the birds to the ingested food.

The microscopic examination of the serosa layer revealed similar structure of this tunic in the ventriculus of francolin and parrot. For instance, Ostrich [33], and turkey[34] the structures also were seen. The mean of thickness of this tunic was 160 µm in both sex of francolin and 120 µm in both sexes of parrot.

Histochemical Findings: The stomach birds such as (proventriculus and ventriculus) were well studied histochemically by applying three stains: PAS, PAS-AB (pH 2.5) and PAS-AB (pH 1.0). These staining techniques were conducted to view the presence or absence of neutral mucins, acidic mucins and sulfated mucin respectively.

Proventriculus: The lamina propria extended between the gastric mucosal glands were moderately reacted with same stain. These findings were akin to those observed by [32] in the black- winged kite glandular stomach. The connective tissue and wall of blood vessels of submucosa and serosa give activist reaction with PAS and smooth muscle fiber in muscularis showed poor staining with PAS (Fig.6). Whereas, [16] has reported variant findings in guinea fowl proventriculus in which the submucosal glandular epithelium showed depressing reaction for mucins post staining with the PAS.

The strong PAS-positive reaction which observed in the francolin glandular stomach mucosa was noticed parrot mucous glands (Fig. 6) and such reaction was similarly documented in previous investigations such as[35] and[36]. Positive reaction toward PAS by the mucosal folds of the glandular stomach may have a protective role in avoiding the effect of hydrochloric acid on the mucous membrane of the proventriculus [34]. Conversely to these findings in francolin and parrot, (Fig. 3, and 6).

The tunica muscularis showed mild reaction with the same stain, while the interspersed collagen fibers showed a moderate reaction in parrot, and francolin (Fig.3, and 6). The epithelium of the mucosal folds secreted acidic sulfated and neutral mucins which were well stained with the combined PAS-AB (pH 1) stain (Fig. 3, and 6). These findings agreed with [38] observations in the proventriculus lining of the domestic duck in which mucosal folds surface lining cellsbestowed red and blue colors with the both parts of this combined stain, respectively.

By using combined PAS-AB (pH 1) on the sections of the proventriculus wall to differentiate the sulfated from non sulfated acidic mucins, positive materials were detected in the lumina of the mucosal glands, lining cells of the surface and the secretory duct of the submucosal glands. The reaction indicated the presence of sulfated and neutral mucopolysaccharides in the francolin andparrot proventricular surface epithelial cells (Fig. 3,6). The current responses of this combined stains were similar to the previous records of [40] in the francolin proventriculus glands which showed PAS positive reaction due to the presence of both acidic and neutral polysaccharides. However, strong reaction was observed in Alcian blue part of the stain in this bird.

The ventriculus (Gizzard): The wall prepared sections of the ventriculus that were stained by PAS-AB (pH 1) revealed positively blue and red colors in the epithelium and gastric glands of the mucosal layer in the studied birds because of the presence of the sulfated and neutral mucopolysaccharides, respectively.

The cuticle covering stained with PAS in francolin whereas, negatively did with that of parrot.

Salivary Sialic Acid Level and Oral Health Statues in Sample of Iraqi Children

Lamia I. Sood[1], Ameena Ryhan Diajil[2]

[1]Assist. Prof., Department of Pop, College of Dentistry, University of Al-Anbar,
[2]Assist. Prof. Department of Oral Diagnosis, Oral Medicine, College of Dentistry, University of Baghdad

Abstract

Background: Saliva is the 1st defense fluid with sialic acid is a significant salivary biomarker. It is an acidic sugar with a nine-carbon backbone, able to mediate a wide variety of patho- physiological processes. the study aims at estimate salivary sialic acid in Iraqi children sample and also find out their association with oral health status.

Method: Unstimulated salivary samples were collected from 100 healthy child, aged 6-13 years for 5-minutes, between 9:00 - 11:00 A.M. gingival index(GI) and Plaque index were measured . According to WHO criteria,the dentition status was examined by dmfs, dmft,DMFS and DMFT. Also, flow rate and the level of salivary sialic acid were estimated.

Results: In the present study,a positive correlation coefficient is recorded between the salivary flow rate and age and statistically reach the level of significance**.** Sialic acid concentration increased with age, but did not reach the level of significant**.**

A male gender showed increase salivary sialic acid level by 0.2 U/L compared to female, but fail to reach the significance

GI and DMFs showed a positive association with sialic acid level (R=0.036,R= 0.0053),but it's not reach the significant. While sialic acid level observed that a significant weak inverse liner correlation with other variables like DMFS and PI,(R=- 0.082,R=-0.066)

The outcomes were exposed to t-test and Pearson's correlation coefficient, Plaque index, GI, flow rate and the dental caries status were significantly positive correlated with the sialic acid levels in saliva.

Conclusion: The salivary factors evaluated in this study may prove to be useful measures for gingival inflammation in children and allow pediatric dentists to target preventive measures appropriately.

Keywords: *Oral health status, Salivary sialic acid, flow rate, dentition statues, children, Iraq.*

Introduction

Sialic acid found in fluid and body tissue,it's are group of monosaccharide that normally occurs at end of sugar chains and its attached to soluble proteins and the surface of cell [(1)]. The level of Sialic acid takes part in various physiological functions, such as cell-to-cell interactions, cell migration, and proliferation[(2)]. S.A interfere between the pathogenic microorganism and host and the important function to regulate the innate immunity.[(3)]

Terminal sialic acid removed, either by enzyme of virulent bacteria (*neuraminidase*) or by inherited disorder *endogenous neuraminidase* of host from sialylated glycoprotein, its could fuse onto the developing plaque surface, playing a role in plaque formation leading to the decimation of host tissue[(4)]. It has been reported that SA is associated with several acute phase proteins that associated with periodontitis[(5)].

Till date, there is next to no information with respect to synchronous examination and measured of salivary SA level of children and oral health status.

The current investigation was along these lines attempted with a point, to not just evaluate the level of SA in saliva of children and also find out their association with oral health status.

Material and Method

Unstimulated salivary samples were collected from 100 healthy child, aged 6-13 years for 5-minutes, between 9:00 - 11:00 A.M. a special forma "structured questionnaire" that was conveyed in Arabic language and sent to the student family.

This forma consisted of two parts:

1st Part: Demography of primary school student

2nd Part: Clinical oral examination which was measured by PI, GI and CI according WHO criteria.

Ethics committee of the present study was approved by collage of dentistry, university of Baghdad

Exclusion criteria were, children having limitation in opening of the mouth, children with orthodontic appliances,children with any systemic disease and who had taken drug (antibiotics)in the last month

After oral examination, unstimulated whole saliva samples from each child are collected at least one hour after breakfast between 9-11 A.M, After the collection and disappearance of salivary froth. Salivary volume is estimated with a measuring sterile test tubes under the standard conditions over 5 minutes. And the rate of secretion was expressed as millilitres per minutes (m/min)[6].

The sialic acid level measured by Using EnzyChrom™ Sialic Acid Assay Kit (USA), The kit utilizes an enzyme coupled reaction in which free sialic acid is oxidized resulting in development of the OxiRed probe to give fluorescence Ex/Em = 535/587 nm and absorbance OD = 570 nm. The sialic acid kit measures in the linear range of 0.1 - 10 nmol with a detection sensitivity ~ 1 Mm concentration

Statistical Analysis: The data were analysis statically by using SPSS version 19.0. Descriptive analysis, analysis of variance,student T-test, linear correlation and multiple linear regression model were used in this present study. The analysis is expected to be $p< 0.05$ as the limit of significance

Results

One-hundred student are involved in the present study with an age ranging from 6- 13 years old, males represent 46% while 54 % were females.

The primary school student distributed in to 4 group : 6-7, 8-9, 10-11 and 12-13 years old

Table 1: Salivary sialic acid mean

	Salivary Sialic Acid					
	Range	**Mean**	**SD**	**SE**	**N**	**P**
Oral hygiene status(Pl index)						
- Mild range from (0.1 -1)	(56.7-58.2)	57.5	1.1	.8	2	0.14[NS]
- Moderate range from (1.1- 2)	(54.9-72.4)	62.4	4.9	.6	59	
- Severe range from(2.1- 3)	(55-69.5)	61.1	4.1	.6	45	
Gingival index						
- Mild (0.1 -1	(54.9-72.4)	61.5	4.8	.8	36	0.65[NS]
- Moderate (1.1-2)	(55.1-72.2)	61.9	4.5	.5	70	
Age group (years)						
6-7	(56-72.2)	62.4	4.9	1.0	23	0.81[NS]
8-9	(55.1-72.4)	61.7	4.7	.8	35	
10-11	(55-70.8)	61.8	4.5	.8	33	
12-13	(54.9-69.5)	60.9	4.4	1.1	15	

	Salivary Sialic Acid					
	Range	**Mean**	**SD**	**SE**	**N**	**P**
Flow rate - categories						
1st (lowest) tertile (< = 1.00)	(55.1-70.2)	62.0	4.2	.6	50	0.63[NS]
2nd (average) tertile (1.01 - 2.00)	(56-72.4)	62.3	4.9	1.0	27	
3th (highest) tertile (2.01+)	(54.9-72.2)	61.2	5.0	1.0	26	
DMFs-categories						
First (lowest) tertile (<= 2)	(54.9-71.6)	61.1	4.3	.7	38	0.47[NS]
Second (average) tertile (3 - 7)	(55.1-72.4)	62.4	5.0	.8	36	
Third (highest) tertile (8+)	(55.1-72.2)	61.7	4.5	.8	33	
DMFS-categories						
First (lowest) tertile (0)	(55.1-72.4)	62.0	4.9	.6	60	0.43[NS]
Second (average) tertile (1)	(56-72.2)	62.9	5.1	1.5	11	
Third (highest) tertile (2+)	(54.9-70.8)	61.1	3.9	.6	36	

As seen in table (1), the unstimulated salivary flow rate ranged from 2.00 ml/min for the highest rate and 0.04 ml/min for the lowest mean rate.

Salivary flow-rate mean for males range from 0.16-0.1 ml/minute as well as female range from 0.01-1.2 ml/minute. In addition to that, salivary flow rate mean of the female

0.322 ml/min is obviously lower than the male 0.431 ml/min, however, the mean difference were unable to reach the level of significance.

Table(2)shows the correlation between sialic acid and study parameters.

A positive strong correlation recorded between flow rate in children and dental age (r = 0.400).

On other hand .there was a statistically a significant correlation between the salivary S.A and GI(p=0.04).

It is obviously noted from table (2) that children suffered from mild gingivitis recorded with lower salivary S.A mean 61.5 u\l compared to those with moderate gingivitis 61.9 u\l and the differences between the numerical value are non-significant when tested statistically

Table 2: Linear correlation coefficient between salivary sialic acid and oral paramater

	Sialic acid level (saliva)
Salivary flow rate	R = - 0.104 p= 0.3 [NS]
PI	R = - 0.066 p = 0.5 [NS]
GI	R = 0.036 p = 0.71 [NS]
CI	R = 0 p< 0.001

Caries experience presented by DMFS (Decayed-Missing-Filled- Surfaces),

Table (1) shows the distribution of the data according to the severity of DMFS in to lowest, average and highest.

Statistically, a significant inverse correlation between the DMFS and salivery sialic acid R= -0.082 (P< 00.1)

Children of high salivary S.A mean had higher DMFS in second(average) 62.9 u\l and its decreased to reach 62.0 u\l at the first(lowest)DMFS and 61.1 u\l at the third(highest) DMFS, but there was non-significant difference between salivary S.A and DMFS, p > 0.001

As seen in figure (1), the mean sialic acid level was lowest (69.9 u\l) in age group range from 12-13 years, and increase to reach the maximum S.A mean 62.4 at age group range from 6-7 years .but the difference did not reach the level of significant. For each one year increase in age, the S.A level expected to increase by average of -0.117 unit.

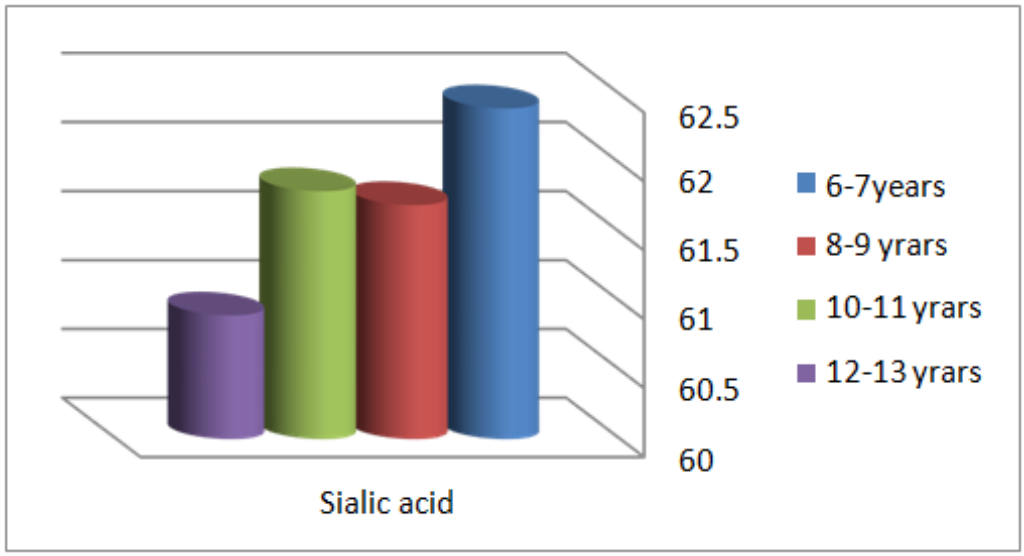

Figure (1): Salivary sialic acid level and age group.

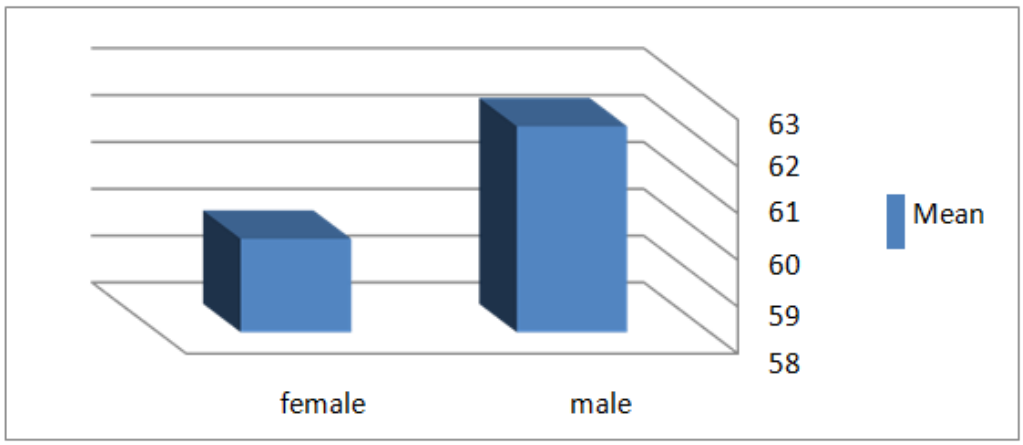

Figure (2): Gender and salivary sialic acid

When comparing salivary S.A mean of the two group,it's found that females are shown to be lower but statistically non-significant as compared to male (p> 0.001) as in figure (2).

Table (1) shows the plaque index classified into mild, moderate and severe index

The majority the student were with moderate pl mean score (62.4),followed with severe (61.1)and just 57.5 of mild score .

Although, mean sialic acid level was higher in student with moderate PI index, statistically failed to reach the level of significant differences between different group of plaque indices.

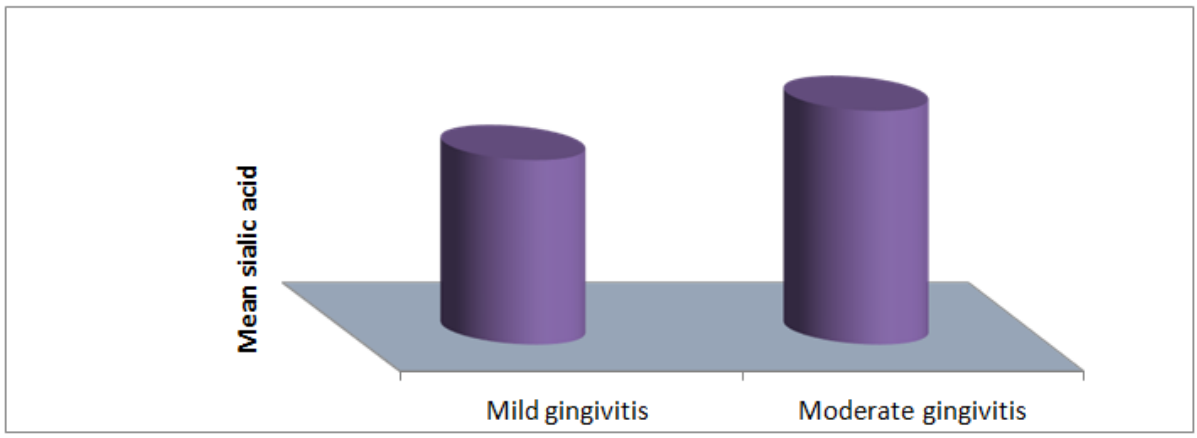

Figure (3): severity of GI in relation to salivary sialic acid mean

Figure (3), shows the GI distributed in to mild and sever gingivitis, with the majority of the student within moderate gingivitis

A multiple linear regression model was performed to evaluate both independent and the net association of the explanatory variables of sialic acid. These variables include: age,gender, salivary flow rate,PLI, GI,, decayed primary and permanent teeth surfaces of the participants.

As shown in table (3), the regression analysis showed that being a male is expected to increase the level of salivary sialic acid by a mean of 0.2 U/L compared to female after adjusting for the possible confounder effect of the other explanatory variables involved in this regression model. However, the effect of gender was unable to reach the statistical significance may be due to a small s sample size.

Table 3: Multiple linear regression model of salivary Sialic acid with other variables.

	Partial egression oefficient	P	Standardized regression coefficient
Constant.	62.2	< 0.001	
Plaque index.	-0.3	0.82 Non-ificant	- 0.025
Gingival index.	2.2	0.56 Non-ificant	0.065
Salivary flow rate.	-0.25	0.57 Non-ificant	- 0.063
DS.	-0.02	0.8 Non-ificant	-0.026
Ds.	-0.04	0.9 Non-ificant	-0.016
Age (years).	-0.117	0.7 Non-ificant	-0.051
Male gender compared to females	0.2	0.85 Non-ificant	0.021

$R^2 = 0.032$, P(Model) = 0.96[NS]

As shown in table 3, the regression model trying to explain the changes in salivary sialic acid was not significant statistically and failed to detect any important or statistically significant association for any of the tested explanatory variables with the outcome variable.

Gingival index and DMFs were positively correlation with sialic acid (r=0.036, r=0.053 (respectively, however fail to reach significance.

Discussion

In present study, SA levels was estimated in salivary samples of primary school students, however, up to our knowledge, no previous studies were found to measure the level of salivary sialic acid in Iraqi children.

The was a negative relation between the age and SA, which agrees with Kuyatt and Baum[7] who found

a significant age related decrease in sialic acid level[7]. The older age group in this study (12-13 years) showed higher precent with teeth missing; that had a negative correlation with sialic acid level. This may be explained by negative correlation between free sialic acid and age in relation to missing teeth with less bacterial infection compared with lower percent of teeth missing.

Also, this agrees with Närhi et al [8], who mentioned that defense mechanism factors which were derived from gingival crevicular fluid were diminished in the absence of teeth [8].

Relation between salivary sialic acid, Plaque and gingival index

The results found a positive correlation between the salivary SA and gingivitis in children. This result is with a line of the result obtained by pervious studies performed by Jawazaly et al [9]. They discovered a significant relationship between gingivitis and

salivary SA [9]. In periodontal diseases,The increase in SA level may be result from raise in sialidase action[10].

Salivary Sialic acid are clearly increase to the individuals with gingival disease,its plays very important role in immunesystem .statistically a significant relationship between the salivary S.A and gingival condition ..

Considering, caries which is a multifactorial in aetiology, increase in caries activity (severity) may be explain by compination of several factores including bacteria,diet

,time and host and oral hygiene .thus, the physiology,composition and flow rate of saliva is the important parameter affecting dental caries susceptibility and altering oral health statues.

The greater part of the proteins in the saliva its glycoprptein, S.A is one of the important structure of salivary glycoprotein that participating in the plaque and acquired pellicle formation in the oral cavity as well as improving bacterial aggregation [12].

Salivary sialic acid level would influenced by oral infections[13,14]. more recently, it has need been accounted that salivary sialic acid level increase with salivary oxidative anxiety [15].

Hypolipidemic and Antioxidant Efficacy of Apigenin in Hydrogen Peroxide induced Oxidative Stress in Adult Male Rats

Mohammed I. Al-Rawi[1], Aous Kahtan Almzaien[1], Kahtan A. Almzaien[2]

[1]Lecturer, [2]Prof., Physiology & Pharmacology Department, College of Medicine, Iraqi Center for Cancer and Medical Genetic Research Mustansiriyah University Medical Lab. Tech. Department, Dijlah University College

Abstract

This study was conducted to assess the role of apigenin extracted from parsley seeds either in glycosidic (aqueous extract) or aglycone forms (organic solvent extract), comparing to butylated hydroxyl tolouene (BHT)in serum lipid profile and brain tissue peroxidation in H_2O_2 induced oxidative stress adult male rats.

The yield of crude flavonoids from parsley seeds was found to be approximately 2.65% and thin layer chromatography techniques confirmed that apigenin is the main flavonoid with RF similar to that of the standard apigenin.

Experimentally induction of oxidative stress in male rats by 0.75% H_2O_2 in drinking water for eight weeks showed a significant alterations in normal serum lipid profile manifested by significant elevation ($p<0.05$) in total cholesterol, Triacyle glycerol (TAG), Low density lipoprotein-Cholestrol (LDL-C) and Very low density lipoprotein-Cholestrol (VLDL-C) and a significant decrease in High density lipoprotein-Cholestrol (HDL-C) as compared to the control and BHT treated groups. On the other hand, daily oral administration of apigenin in a dose of 150 mg/Kg B.W. to H_2O_2 treated groups were caused a significant correction of the lipid profile parameters.

Examination of brain tissues of H_2O_2 and apigenin concurrent H_2O_2 treated rats showed a significant decrease ($p<0.05$) in brain tissue malondialdehyde (MDA) and significant elevation in catalase and cholinesterase activities in apigenin and BHT treated groups comparing with H_2O_2 treated and control groups.

Keywords: *Hypolipidemic, Antioxidant, Apigenin, Hydrogen Peroxide,, Oxidative Stress, Rats.*

Introduction

Recent attention has been given to the influence of dietary factors on health and mental well-being [(1)]. There are convincing evidences that the oxidative stress and reactive oxygen species (ROS) play an important role in the etiology and/or progression of a number of human diseases[(2)]. It is known that oxidative stress is associated with many diseases including neurodegenerative disorders.

Many factors contribute to the degeneration of neural cells, leading to functional deterioration of neural cells, leading to functional deterioration of neurons and neurodegenerative disorders. Hence, because of their high metabolic activities and low antioxidant defense capacities, neural cells in brain are more vulnerable to oxidative stress[(3)]. In addition, hydrogen peroxide is produced in β-amyloid (Aβ) aggregation, dopamine oxidation, and brain ischemia/reperfusion, AB aggregation is known to cause oxidative damage in neurons, including protein and lipid oxidation and DNA damage[(4)].

The main class of natural antioxidants is exerting cardioprotective, chemopreventive, and neuroprotective effects. The biological activities of flavonoids have been attributed to their antioxidant, anti-inflammatory, anticancer, neuroprotective and signaling properties[(1,5)]. A clear understanding of the mechanisms of action, as either antioxidants or signaling molecules, is crucial for the application of flavonoids as interventions in

neurodegeneration and as brain foods[6]. Some flavonoids (like apigenin) can also traverse the blood-brain barrier; hence they are promising candidates for intervention in neurodegeneration and as constituents in brain foods[7].

Apigenin (4, 5, 7 - trihydroxyflavone) is a dietary flavonoid commonly found in many fruits and vegetables[8]. It has been found that apigenin inhibits tumor growth and angiogenesis agent induced by different cancer cells[9].

However, the role of apigenin as antioxidant and in neuroprotection is not so clear therefor, this study was conducted in order to investigate the following:

1. Extraction of apigenin from parsley seeds and conformation of the structural components using (TLC) in comparison with standard apigenin.
2. Assessment the role of apigenin as either Glycoside and/or Aglycone in serum lipid profile and brain lipid peroxidation in oxidative stress male rats.

Materials and Method

Parsley seeds were obtained from commercial sources (Baghdad) and the vouchers specimen of the plant were deposited to be identified and authenticated at the National Herbarium of Iraq botany directorate in Abu-Ghraib under scientific name *petrselinumsativum* belongs to the family umbilifera. After cleaning and milling crushed seed was kept in dark and dry place.

The method of Harborne[10] modified by Al-Kawary[11] was used for the extraction of apigenin in aglycone form, while the method of Ikhan[12] was used for apigenin extraction in Glycoside form.

Thin layer chromatography on Silica gel type G aluminum plates (20 x 20 cm) at a thickness of 0.25 mm supplied from Fluka Company was used for the identification of apigenin either in Aglycone or Glycosidic form. Toluene: ethyl-acetate: acetic acid (36:12:5) was used as mobile phase [13] and UV detector to explore the spots on 254ηm.

Fifty adult male Albino Wister rats weights (250-300) gm, 10-12 weeks of age were randomly divided into five groups; Group (c), Rats of this group were allowed to ad libtium supply of drinking water and served as a negative control group. Group (T1), rats were allowed to 0.75% H_2O_2 in drinking water and served as a positive control group. Group (T2) rats, were allowed to 0.75% H_2O_2 plus daily oral administration of BHT, 25 mg/kg B.W.[14], using gavage needle. Group (T3) rats were allowed to 0.75% H_2O_2 + 150 mg/kg B.W of apigenin in glycosidic form. Group (T4) rats were allowed to 0.75% H_2O_2 + 150 mg/kg B.W of apigenin as Aglycone.

Blood and brain tissue samples were collected after four and eight weeks of experimental period, five animals from each group were sacrificed for blood and brain tissue analysis, immediately after blood collection, each animal was killed and the head was separated and quickly preserved in liquid nitrogen until analysis.

Serum samples were used for the measurement of total cholesterol according to[15] using Randox assay kit. Triacylglycerol using Biomerieux kit[16]. High density lipoprotein (HDL-C) measured enzymatically using linear enzymatic Kit (Linear chemicals, Barcelona, Spain).

Serum low density lipoprotein cholesterol (LDL-C) and VLDL-C were calculated according to[17].

Brain tissue samples were used for the measurement of cholinesterase activity according to[18], catalase activity according to[19] and malondialdehyde concentration[20].

Statistical analysis of data was performed of two way analysis of variance (ANOVA) using significant level of ($p<0.05$). Specific group differences were determined using least significant difference (LSD) as described by [21].

Results and Discussion

Parsley dry seed contains approximately 2.65% flavonoids (apigenin). The RF values of extracted apigenin in glycosidic form was 0.477, similar RF values under the same experimental conditions was recorded by [13], while the corresponding values for apigenin in aglycone form was 0.554. The higher RF values in aglycone form may attribute to the remove of sugar moiety from the molecule.

Oral administration of 0.75% H_2O_2 to male rats caused a case of hypercholesterolemia and hypertriacylglyceridema manifested by a significant $p<0.05$ elevation in TC, LDL-C, TAG (table 1, 2, 3, 4) and reduction in HDL-C (table 5), and this may reflect the potent oxidative effectiveness of H_2O_2 which caused an oxidative damage by free radical generation (superoxide anion, hydroxyl radical), led to a subsequent complication and the development of oxidative stress[22].

Administration of 0.75% H_2O_2 caused a significant increase in the circulating total cholesterol, LDL-C, VLDL-C and also in the ratio of TC: HDL-C and LDL-C: HDL-C. HDL-C inhibits the uptake of LDL-C by the arterial wall and facilitates the transport of cholesterol from peripheral tissue to the liver where they are catabolized. Then a decrease in plasma HDL-C leads to an elevation of LDL-C[23]. Besides, increment of TAG level in animals received H_2O_2 in the present study may be due to an increase in serum VLDL-C level which acts as a carrier for the TAG [24].

Anyway, hydrogen peroxide (0.75%) used in this study may be considered as exogenous stress factor in the production of ROS which media the damage of the cell structure including nucleic acid, proteins and lipids which lead to a consequent alteration in lipid profile and an elevation in total cholesterol [25, 26].

Moreover, the relationship between serum cortisol, adrenaline and lipid profile under different stress conditions have been documented by a number of workers [26, 27].

Adrenocorticotropic hormone (ACTH) stimulates the synthesis of adrenaline and cortisol precursors, and the role of these stress hormones in the production of more energy in the form of metabolic fuels, fatty acids and glucose is well documented these substances require the liver to produce and secrete more LDL, which is the main carrier of cholesterol in the blood and finally elevated cholesterol level [28, 29]. In this regard, the hypothesis postulated by [30] that oxidation stress brought about by the combination of excess liver iron and copper deficiency should be also considered since oxidative stress have a considerable role in hemolysis of RBC because of the depletion of antioxidant and particularly glutathione which play a major role in the protection of red blood cell membrane. The high iron level may increase both free radical formation and hyperlipidemia.

The hypolipidemic effect of flavonoid, (apigenin) may be attributed to the fact that cells respond to phytochemical through direct interaction with receptors or enzymes involved in signal transaction, or through modifying gene expressions [31, 32].

So, apigenin may limit cholesterol biosynthesis by inhibiting 3-hydroxy -3-methylglutaryl-CoA reductase (HMG-CoA reductase) or by enhancing the phosphorylation of HMG-CoA reductase indirectly thus minimize endogenous cholesterol production, and reduces apo B secretion in hepatocytes [33, 34] or, binding to cytoplasmic steroid receptor due to hydrophobicity of their aglycone portion. Moreover, flavonoids (apigenin) may intercalate between the DNA segments, leading to transcription of gene involved in lowering blood cholesterol[34, 35].

Oxidative status of brain tissues: Malondialdehyde (MDA) concentration, catalase and cholinesterase activity of brain tissue were considered in this study as a biomarker of H_2O_2 induced oxidative stress.

A significant ($p<0.05$) elevation in MDA was observed in H_2O_2 treated group after four and eight weeks of the treatment. Increase of MDA level may be due to an increase in free radicals production more than the ability of scavenging system, hence, elevated FRs cause a gradual cell injury by lipoxygenase enzyme which oxidized unsaturated fatty acids and subsequent production of excess MDA [36, 37].

Free radicals may also induce injury by induction of gene expression regulated by nuclear transcription factor and jun-NH_2-terminal kinase (JNK)a stress protein leading to cellular damage[38, 39].

After 4 and 8 weeks of treatment with BHT and apigenin (150 mg/kg B.W. as Glycoside or aglycone) no significant differences in MDA concentration in the brain tissue was recorded among the antioxidant treated groups. Improving the oxidative stress H_2O_2 treated groups was confirmed the scavenging and potent LPO inhibition capability of the apigenin and BHT. Apigenin may considered a part in indirect inhibition of nuclear transcription factor B, resulting in a decrease in the formation of,adhesion molecules, chemokines, pro-inflammatory cytokines, TNF, IL6 and IL8, as well as, binding to DNA strand [40].

Brain tissue catalase activity (Ku/100gm wet tissue) in H_2O_2 treated group, there was a significant decrease ($p<0.05$) during the experimental period, while no significant alterations was recorded in apigenin and BHT treated groups. Excessive H_2O_2 production with diminution of antioxidant enzyme and subsequent reaction of H_2O_2 with reduced iron to produce hydroxyl radical via Fenton reaction [41] has been postulated to cause elevation in ROS with depletion of antioxidant[42].

Besides, oxidative stress in the brain is associated with increased calcium ion concentration and increased mitochondrial demand leading to an increase in the

formation of ROS and RNS by disturbing respiratory chain and activation of series of enzyme like nitric oxide synthase and xanthine oxidase which stimulate ROS formation and antioxidant enzymes depletion [(1)].

On the other hand, the significant role of apigenin in ameliorating of antioxidant status may be attributed to its capability in inhibiting the activity of xanthine oxidase[(43)], lipoxygenase and cyclooxygenase enzymes[(44)].

Moreover, Hydrogen peroxide treated group also showed a significant decrease in brain tissue cholinesterase activity and this may be attributed to the role of H_2O_2 in the oxidation of the Trp_{432}, Trp435 and Met 436 residues in the active site of the enzyme resulting in conformational changes and loss of the physiological function[(45)].

However the result of this study confirmed that apigenin has no neuroprotective effect within the concentration of H_2O_2 used because acetylcholinestrase activity is H_2O_2 concentration dependent and inhibited at high H_2O_2 concentration (10^{-3} M) and activated at low concentration (10^{-6} M) [(45)] as well the dose of apigenin used may not effective to reactivate the enzyme, although the possible mechanisms underlying the neuroprotection of flavonoids against H_2O_2 induced oxidative damage in PC_{12} cells was recorded by [(1)].

Detection of *Propionibacterium* in Samples by Metagenomic Analysis that Collected from Patients Suffering Acne Vulgaris in Babylon Province

Rabab J H AL-Hasseny[1], Lamees A. Abdul-Lateef[2], Hussein Abbas AL-Sultany[3]

[1]Assist. Lect., Microbiology/College of Food Science, AL-QasimGreen University, Iraq, [2]Prof., Department of Microbiology, College of Medicine, University of Babylon, Iraq, [3]Prof., Venereology and Dermatology, College of Medicine, University of Babylon, Iraq

Abstract

By the metagenomic analysis detected the microorganisms in acne disease. The Taxonomic assignment of the sequences determined classified them into diverse microorganisms. In present study the microorganisms were bacteria (95.29%), eukaryote (4.23%), viruses (0.29%), archaea (0.04%), other sequences(0.15%) and unclassified sequences (0.00)these results determined for PA1. similarly, the PA2 was contains bacteria (96.52%), eukaryote (3.15%), viruses (0.18%), archaea (0.05%), other sequences(0.08%) and unclassified sequences (0.00). The identified and taxonomic of the bacteria that apparent high presenting 95.29% and 96.52% for each PA1and PA2 respectively. According this results taxonomic of bacteria to genus present to detected the important genus was infection acne. The PA1 sample was similarity with PA2. The genus bacteria for (PA1 and PA2) were *Corynebacterium* (34.67%, 40.32%), *Propionibacterium* (32.23%, 24.04%), *Staphylococcus* (24.54%, 24.18%), *Malassezia* (1.13%, 0.86%), *Bacillus* (0.92%, 1.99%), *Pseudomonas* (0.54%, 1.17%), *Escherichia* (0.36%, 0.52%), *Acinetobacter* (0.33%, 0.58%), unclassified (0.32%, 0.20%), *Stenotrophomonas* (0.31%, 0.51%), *Meiothermus* (0.30%, 0.36%) and *Enterococcus*(0.17%, 0.45%) whereas the PA2 have 0.18% of *Streptococcus* but the PA1 not appearance *Streptococcu.*

Keywords: *Babylon Province, Propionibacterium acnes, the metagenomic analysis, acne vulgaris.*

Introduction

Propionibacterium acnes is a nonspore- forming, gram- positive, anaerobic, pleomorphic rod whose end products of fermentation include propionic acid[(1)]. *P.acnes*is considered an opportunistic pathogen, causing a range of infections as well as being associated with a number of inflammatory conditions. Itis primarily recognized for its role in acne vulgaris where it is thought to contribute to the inflammatory phase of the condition[(2)].

Propionibacterium acnes, which are a normal inhabitant of the skin, produce fatty acids that inhibit the growth of fungi on the skin.[(3)]. However, when it becomes trapped inside the hair follicle, it may grow and cause inflammation and acne infection[(4)].

Metagenomic functional analysis revealed that same of chemical pollutant that effected the structure and function of microbial community[(5)]. Metagenomic analysis was applied to illustrate the metabolic potential of microbial consortium for the degradation of polluted soil, and this could provide additional information of function conducted by un-culturing bacteria[(6)]. The field of metagenomic developed as a consequence of the diversity that prokaryotic diversity was much greater than previously realized and that the prokaryotic population.[(7)]

The classification method of metagenomics sequencing data can be divided into two categories according to different sample data processed method: one is based on the sequence of marker genes such as 16SrRNA (marker gene metagenomic) and other is based on whole-genome sequencing fragment (shotgun-sequences metagenomic)[(8)].

Materials and Method

Samples Collection: 2 samples (Name these two samples PA1 & PA2) from two patients were subjected

for sampling which include both skin sites (comedown) for the sampling was forehead from both sexes and the age of patient was 17 and 18 years. These patients were diagnosed by dermatology physician, according to the signs and symptoms,, in addition to be having risk factors that were determined by the information about patients . In this study, patients with recent usage of local antibiotic treatment and usage cosmetic material were excluded from sampling.

DNA Extraction for Gram positive Bacteria: DNA extraction was carried out according to the genomic DNA purification kitsupplemented by manufactured company (Gene aid, UK).

Whole Genome Sequencing (WGS) and Analysis: 2 samples of DNA isolated from patients with acne were selected for whole metagenome sequencing based on the next-generation sequencing technique. After extraction of Genomic DNA, the extracted DNA subjected to quantification by Nano Drop instrument to estimate the DNA concentration according to manufacturing's instructions. In addition, the condition of the DNA was assessed by gel electrophoresis method to evaluate the presence or absence of DNA in the sample, where 1µl of DNA loaded to 1% agarose gel and run at 160V for 30min. Following this step, only successful samples were submitted to Macrogen company (Korea) for whole metagenome sequencing (Paired-ends) using the Illumina NovaSeq 6000 platform. The resulted raw reads were processed by further bioinformatics tools.

The raw data were analyzed by several bioinformatics tools. All bioinformatic approaches which used to analyze the study sequences were depend on either using command-line tools and bioinformatics softwires on open-source operating system, Linux (Version: Ubuntu 18.04.3 LTS, Canonical Ltd., UK), Windows-based program (CLC Genomics Workbench version 20.0.3) or using web-based servers such as the Galaxy platform (https://galaxyproject.org)[9]. Before WGS analysis, the raw data undergo quality control by FastQC (Version, 0.11.5) [10] to evaluate quality of reads and calculating the basic statistics (such as total number of bases, reads and GC content). After quality control, raw reads were subjected to preprocessing steps to reduce biases in analysis by trimming out bases of low quality, adapter sequences, the Poly-G tail and human DNA. Trimmomatic (version 0.36) tools [11] and CLC Mapper (CLC Genomics Workbench version 20.0.3). The filtered raw data have undergone for further processing steps summarized with its tools and references in Table (1).

Table (1): The Bioinformatics tools or programs which used for analyze the filtered raw data

Results and Discussion

By the metagenomic analysis detected the microorganisms in acne disease. The Taxonomic assignment of the sequences determined classified them into diverse microorganisms. In present study the microorganisms were bacteria (95.29%), eukaryote (4.23%), viruses (0.29%), archaea (0.04%), other sequences(0.15%) and unclassified sequences (0.00) these results determined for PA1. similarly, the PA2 was contains bacteria (96.52%), eukaryote (3.15%), viruses (0.18%), archaea (0.05%), other sequences(0.08%) and unclassified sequences (0.00) depended on the Pie chart in Figure (1) and (2).

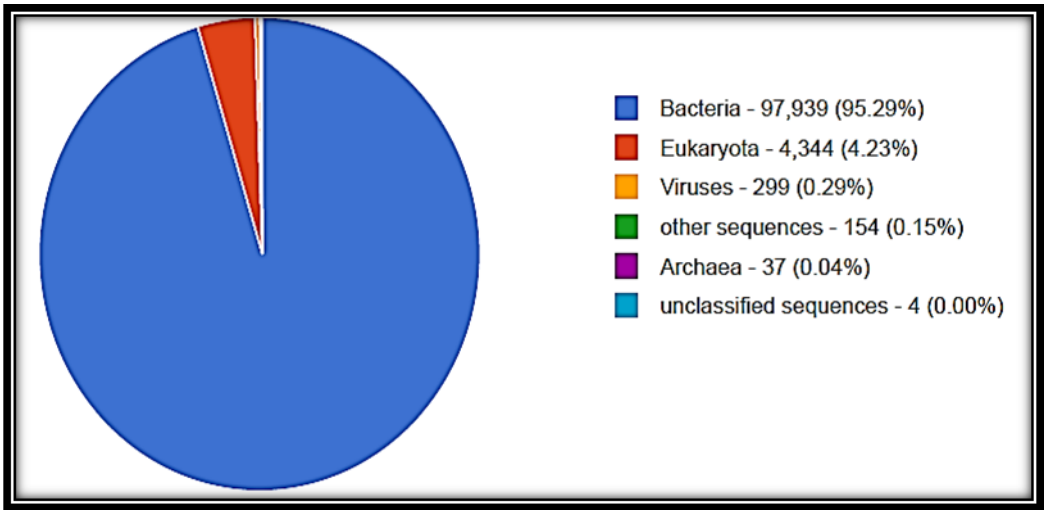

Figure (1): Pie chart represents the distribution of domain taxa of PA1.

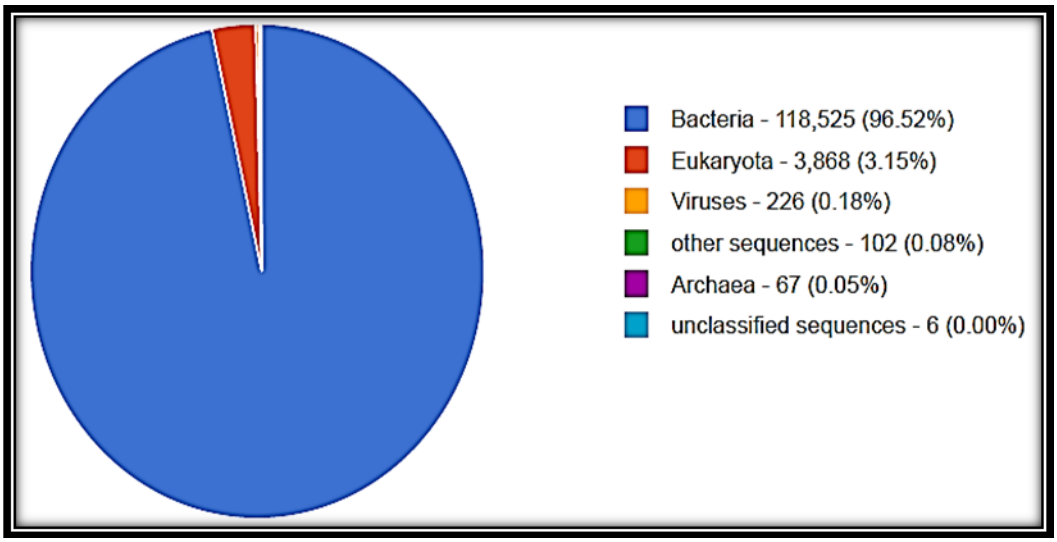

Figure (2): Pie chart represents the distribution of domain taxa of PA2.

The bacteria in the above results was higher than other microorganisms in two samples. It was 95.29% and 96.52% for each PA1and PA2 respectively. These results detected the bacteria is a major source in acne diseases compared with other microorganisms additionally several studiesidentified bacteria in acne vulgarism. So many factor increasing the bacteria in acne lesions may be the bacteria have multi –virulence factors, generation time, resistant to inhibiters growth that secreted by skin and other factors.

Correlated the results with [18] The surface of the skin is cooler than the core body temperature and is slightly acidic, and squares are continuously shed from the skin surface as a result of terminal differentiation.

The results agreements with [19] they documented The microbiome includes bacteria, fungi, viruses, parasites, and micro-eukaryotes which play significant role in dermatological disorders.

The metagenomic analysis as important part of this study was to identified and taxonomic of the bacteria that apparent high presenting 95.29% and 96.52% for each PA1and PA2 respectively. According this results taxonomic of bacteria to genus present to detected the important genus was infection acne. The PA1sample was similarity with PA2. The genus bacteria for (PA1 andPA2) were *Corynebacterium* (34.67%, 40.32%), *Propionibacterium* (32.23%, 24.04%), *Staphylococcus* (24.54%, 24.18%), *Malassezia* (1.13%, 0.86%), *Bacillus*

(0.92%, 1.99%), *Pseudomonas* (0.54%, 1.17%), *Escherichia* (0.36%, 0.52%), *Acinetobacter* (0.33%, 0.58%), unclassified (0.32%, 0.20%), *Stenotrophomonas* (0.31%, 0.51%), *Meiothermus* (0.30%, 0.36%) and *Enterococcus*(0.17%, 0.45%) whereas the PA2 have 0.18% of *Streptococcus* but the PA1 not appearance *Streptococcus* such as according to the pie charts in below in the Figures (3) and (4).

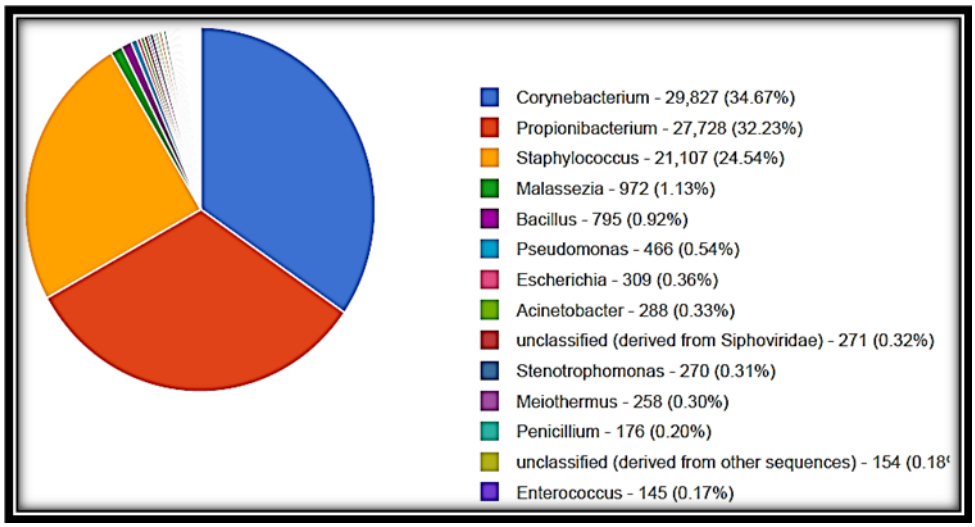

Figure (3) Pie chart represents the distribution of genus taxa of PA1.

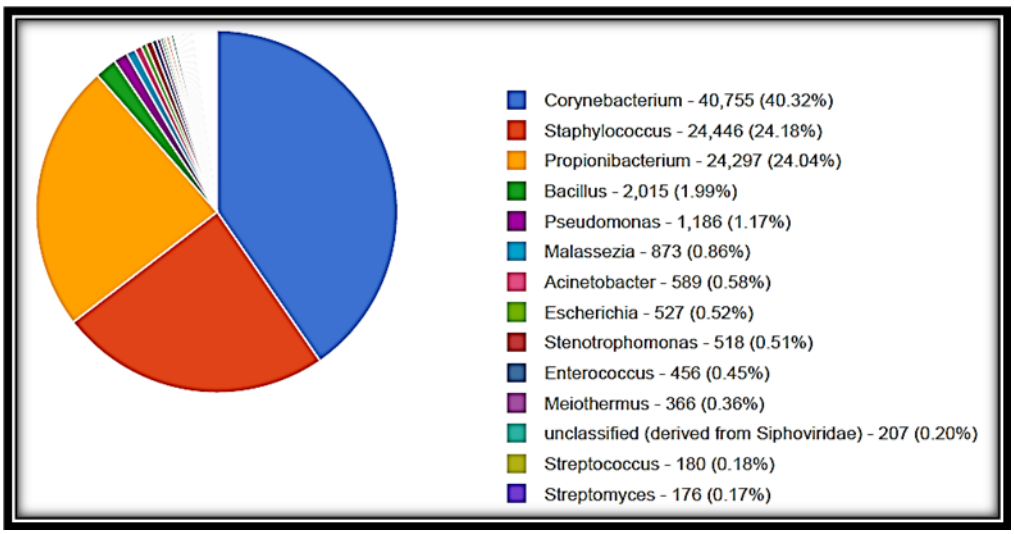

Figure(4) Pie chart represents the distribution of genus taxa of PA2.

The results showed that PA1 and PA2 were similarity in three major bacteria included *Corynebacterium*, *Propionibacterium*, *Staphylococcus* whereas the two samples were significant difference of percentages for the other bacteria. It mainly consists of sebaceous areas, moist areas, dry areas, and sites containing varied densities of hair follicles, skin folds, and skin thicknesses. Sebaceous glands being relatively anoxic support the growth of facultative anaerobes such as acne causing *Propionibacteriumacnes*, which contain lipase-encoding genes that degrade skin lipids of sebum as revealed by full genome sequencing [(20).]

The primary microbe associated with development of acne is Propionibacterium acnes, also a prominent member of the commensal skin microbiota. Topical and systemic antibacterial drugs have long been used to treat acne, with the efficacy commonly attributed to decreased P. acnes colonization and/or activity[(21)].

Expression Levels of Efflux Pump *mexR* and *norA* Genes in Multi-Drug Resistant in Some Bacteria by Using Quantitative RT-PCR Under Stress of Effect Efflux Pump Inhibitors

Baidaa Adel Ibrahim[1], Mayadaa Abdullah Shehan[2]

[1]Post Graduate Student, University of Anbar, College of Sciences, Department of Biology, Iraq,
[2]Assist. Prof. Dr. University of Anbar, College of Sciences, Department of Biology, Iraq

Abstract

The study was suggested because of the major role of multidrug-resistant *Pseudomonas aeruginosa and Staphylococcus aureus* in a wide range of clinical infections besides increasing a high resistance against the commonly used difference antibiotic. The efflux pumps have a vital role in multidrug resistance for extruding many toxic materials and antibiotics. This study aimed to measure the expression level of efflux pump genes in MDR *Pseudomonas aeruginosa* and *Staphylococcus aureus* using RT-qPCR technique. In this study, one hundredclinical isolates of MDR*P. aeruginosa* and *S. aureus* isolated from wounds were examined, then 20 isolates selected based on their ability as MDR and wereexposed to different concentrations of Ethidium Bromide (Cartwheel method) to determine the presence of efflux pumps activity. Efflux pump genesmexR, and norA were screened by PCR. The results demonstrated the presence of mexR and norA genesin all MDR isolates. RT-qPCR assay was used for investigating the efflux pump genes expression. The difference in gene expression between active and nonactive efflux pumps was determined when exposed to the antibiotics and efflux pump inhibitors.

Keywords: *Efflux pump inhibitors, mexRgene, norAgene, gene expression, RT-qPCR.*

Introductions

The multidrug resistance is becoming a dangerous problem in the treatment of resistant bacterial infections. The MDR, by definition, is the capacity of pathogens to resist lethal doses of drugs, various in their mode of action and structure, which would be effective in the removal of susceptible isolates of pathogens(1). Among infections caused by Gram-negative rods, *P. aeruginosa* bacteria are the most serious and opportunistic pathogens that cause a high rate of mortality and morbidity in most hospitalized patients(2). Recently, these bacterium infections are caused one of the main problems in hospitals and that are relevant to high rates of mortality, ranging from 18% to 61%(3).

Staphylococcus aureus pathogen remains one of the more serious bacterial pathogens in the public health field because of its high virulence, and also able to cause multiple diseases varying from complicated skin and skin structure infections (cSSSI) to life-threatening situations, like pneumonia, endocarditis and toxic shock syndrome(4).Efflux pumps have revealed as specific key drivers for antimicrobial in both Gram-negative and Gram-positive bacteria, EP also is vital in other different physiological processes like stress-adaptations, pathogenicity, virulence factors, and transportation of necessary nutrients(5). The MDR efflux systems are found in whole bacterial species. These pumps are proteins, which are the capacity of transporting substrate materials with different sizes and properties from the inside cell to the extracellular area of the bacterial cell(6). Efflux pumps are classified into fivefamilies;the resistance nodulation cell division(RND) families, major facilitator subfamily(MFS),small multidrug regulator(SMR), energy-dependent ATP-driven pumps are the ATP-binding cassette (ABC) family and the multidrug and toxic compound extrusion(MATE)(7). *mexR*is a regulatory gene of MexAB-OprM operon and was located upstream of the *mexAB-oprM*operon, also encoding a repressor protein of MarR family, andMexR protein was endowed with oxidation-sensing mechanism which regulates virulence and antibiotic resistance in *P.*

aeruginosa(8). The Efflux pump*norA* is a member of MFS family. Which is a chromosomally encoded protein with 12 transmembrane-spanning segments, also is a proton motive force (PMF) dependent multidrug efflux pump in *Staphylococcus aureus.norA*is a 388 aminoacid protein and reveals to release a diversity of structurally unrelated drugs, like fluoroquinolones, cetrimide, benzalkonium chloride, tetra phenyl phosphonium bromide, ethidium bromide, and acriflavine(7)**.**

Materials and Method

Bacterial Isolates and Identification: Onehundredisolates of *Pseudomonas aeruginosa* and *Staphylococcus aureus* isolated from wounds. All bacterial isolates were identified based on morphological characteristics on culture media and biochemical tests (9)**.**Additionally,the diagnosis of all isolates was carried out by the Vitek-2 compact system(Biomerieux, France) using GNR-ID and GPC-ID card(10).

Estimation of Efflux pump activity by Cartwheel method: The cartwheel method was described by (11)to determine the presence or absence of efflux activity within bacterial selected isolates according to the multidrug-resistant pattern. Twenty selected isolates activated on 5ml of (TSB) and incubated at 37°C for 18h. Tryptic soy agar plates containing (EtBr) at concentrations of 0 to 2.5 mg/L, and kept away from light. Bacterial cultures were streaked on EtBr-TSA plates. After chosen a proper concentration, cultures were swabbed on EtBr-TSA plates starting from the center of the plate and spreading towards the edges, Agar plates were incubated overnight at 37 ºC and then examined under U.V transilluminator.

Genomic DNA Extraction: The extraction of DNA was carried out for Twenty *Pseudomonasand Staphylococcus* isolates using DNA Mini kit extraction depending on the instruction of the manufacturing company (Promega, USA).

Detection of the efflux pump genes by Conventional PCR: Uniplex PCR technique was performed to amplify efflux pump genes (mexR and norA) of *Pseudomonas aeruginosa* and *Staphylococcus aureus* respectively. The stock solution of primer was prepared from Lyophilized primers (macrogen,Korea). The specific primers used in this study are listed in Table (1). A typical PCR mixture contained 12.5µl master mix (*Taq* polymerase, MgCl2, PCR buffer and dNTPs), 1µl each of forward and reverse primers, 4µlof DNA and 6.5µl of free water adjusted to a total volume of 25. After centrifuged, the mixture transferred to a thermal cycler to start reaction according to the steps of the suitable program for each gene.

Table (1): Sequences of primers that use for conventional PCR.

Total RNA extraction and Synthesis of cDNA: Total RNA was extracted using TRIzoL Reagent RNA Isolation kit (Wizbio, Korea) following the manufacturer recommendations.

By using RT Premix cDNA synthesis protocol (Bioneer, Korea): 15 µl of RNA template and 5 µl Rnase free water were added to theRT PE mix tube. The tube was placed in a thermal cycler programmed. cDNA was performed according to the following procedure; annealing step for 10 min at 37°C, cDNA synthesis for 1 hr at 42°C, heat inactivation for 5 min at 95°C.

Quantitative Real-time PCR (RT-qPCR) assay: Transcription of mexR and norA genes were determined in the 4 MDR *P. aeruginosa* and 4 MDR *S. aureus* isolates. The amplification reaction of the fragment of mRNA was performed with the following master amplification reactionin 10µlof qPCR Mix, 1X, specific primers Table (2); (1µlof forward primers and 1µl of reverse primers), 5µl of cDNA synthesis and 3µl of Nuclease-free Water. Thermocycler Program was used for quantitative RT-PCR as follows: Initial denaturation for 60 sec at 95°C, denaturation for 15 sec at 95°C, annealing/extension for 30 sec at 60°C, the fluorescence

readings were taken after each cycle following the extension step. Then it was followed by a melting curve analysis of 60–95 °C.

A gene *gyrB* housekeeping gene was used as a reference gene. The ΔΔCt method was used for measuring the gene expression. The normalized target amount in the sample was equal to **2-ΔΔCt** and also this value can be used to compare expression levels in the samples(12).

Figure (1): Agarose gel (2%) electrophoresis of PCR products formexR gene (162bp). Lane M: 100bp DNA ladder; lanes 1-10 represent bands of Multidrug resistance *P. aeruginosa* isolates. (75-80V/cm^2 for 2 hr).

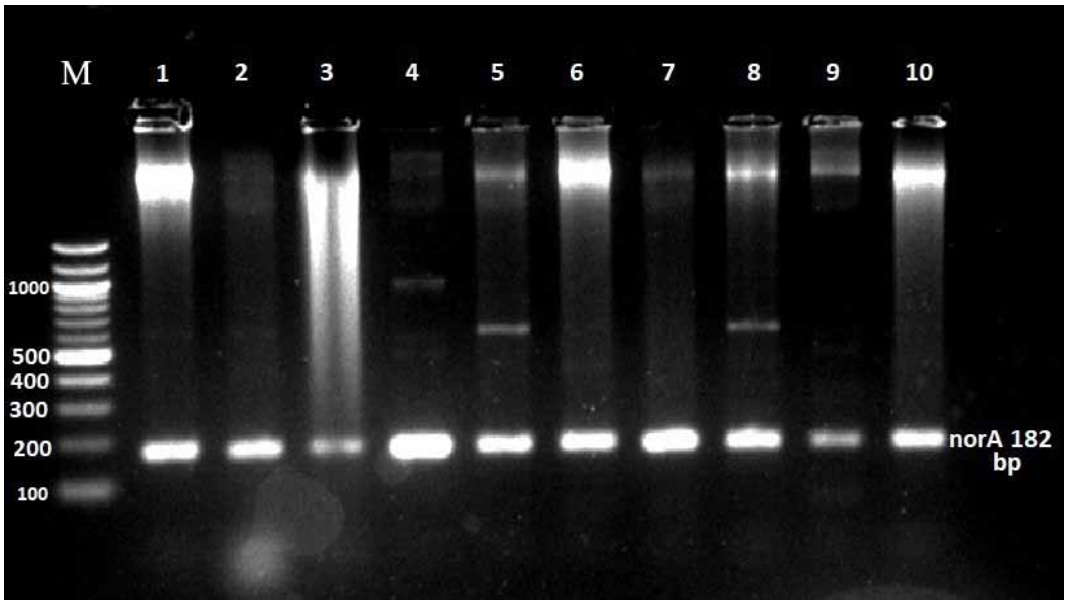

Figure (2): Agarose gel electrophoresis (2%) of PCR products (75-80V/cm^2 for 2 hr) for the efflux pump gene *norA* (182bp). Lane M: 100bp DNA ladder; lanes 1-10: Multidrug resistance *S. aureus* isolates.

Results and Discussion

Efflux pump activity by cartwheel method: The detection of efflux pumps by using different concentration of TSA-EtBr agar plates ranging (0 to 2.5 mg/L), each plate with specific concentration cultured with 20 isolates of *P. aeruginosa and S. aureus* in the form of a cartwheel, after incubation period the result recorded under UV light detects the presence or absence of fluorescence in the mass of bacterial growth, the result identified twenty isolates were grown with higher efflux activity (at concentration 2mg/L). These results were agreed with(13).

Determination of efflux pump genes (*mexR*, *norA)* by PCR: The extracted samples in this experiment have been used to detect the presence of genes encoding efflux pumps and investigation of the genes in bacterial isolates uniplex PCR technique for each DNA. The PCR assay included 20 isolates for the determination of the efflux pump *mexR* and *norA*genes. The PCR products have been confirmed by analysis of the bands on gel electrophoresis. A study by (14)in Egypt,revealed that*mexR* gene was detected in 16 isolates. *mexR* was an important regulatory gene of MexAB-OprM operon,this gene was located upstream of the *mexAB-oprM*operon(15).

Also, the results of the PCR technique for chromosomal efflux pump gene*norA*was observed inisolates of MDR*S. aureus*. In Iraq, a study by(7), out of a total of 96 multidrug-resistant isolates of *S. aureus*, the number of isolates that carried the gene *norA*were 77 isolates (80.21%).

The expression of chromosomal efflux pump genes byRT-qPCR: The major role of this step was to determine the gene expression levels of the chromosomal efflux pump genes in clinical isolates. The presence gene *mexR* and *norA* in bacterial isolates, and compare the gene expression in the presence and the absence of the antibiotics to prove the role of efflux pump genes in the resistance of *P. aeruginosa and S. aureus,* also to compare the gene expression in the presence of the inhibitors to restore the sensitivity of MDR efflux pumps to the antibiotics against which they were developed.

The calculation of gene expression fold change was made using relative quantification(16).For the active efflux pump, the fold of gene expression of *mexR* gene for the three groups (treatments) in addition to untreated group ranged from 1 to 7.86, for an untreated group the fold of *mexR*gene was 1.0. While for the nonactive efflux, the fold of gene expression of mexR gene was ranged from 1to 3.70, also for the untreated group the fold was 1.0. The result of the gentamicin group fold of *mexR* gene (active efflux) was (7.86)and this result was higher (3.70) than the fold of *mexR* gene of (non-active efflux). The PAβN group fold of *mexR* gene (active) was

0.64 and this result was higher (0.47) than the fold of (nonactive). The Phenothiazine group fold of *mexR* gene (active) the result was 1.16 and this result was higher (0.80) than the fold of (nonactive). The results of *mexR* effluxpump gene expression are revealed in table (3).

In this study, when the results of gene expression of fold for antibiotics and synthetic products were compared; it was found that the gene expression was significantly higher when the antibiotics used. Briefly, the gene expression was significantly higher in the gentamicin group than synthetic products, despite the variations in the expression levels of the gene in the gentamicin group, exposure to antibiotics induced the expression of *mexR* gene in the isolates of *P. aeruginosa* studied. Exposure to synthetic products was leading to a decrease in the expression of *mexR* gene in the isolates, except phenothiazine was increased the expression of *mexR* gene in isolates that possess active efflux. The results of gene expression indicated the important role of *mexR* gene in the resistance of gentamicin antibiotics. RND pumps contribute most significantly to antibiotic resistance: MexAB-OprM, MexCD-OprJ, MexEF-OprN, and MexXY-OprM, MexBtransports β-lactams; β-lactamaseinhibitorsandcarbapenems (notimipenem), aminoglycosides, fluoroquinolones, tetracyclines, dyes, and several homoserine lactones involved in (QS)(17).

Table (3): Fold of *mexR* expression Depending on $2^{-\Delta Ct}$ Method

Groups	Isolate	Fold of gene expression
Gentamicin	C+D	3.70
	A+B	7.86
PABN	C+D	0.47
	A+B	0.64
Pheno	C+D	0.80
	A+B	1.16
Untreated (Control)	C+D	1
	A+B	1

The mechanism of MexRregulatedantibiotic resistance is due to the formation of intermonomer disulfide bonds in MexR dimer that leads to its dissociation from promoter DNA, also derepression of the mexAB-oprM drug efflux operon, and increased antibiotic resistance of pathogene. PAβN inhibitor was broadly active against MexAB-OprM, MexEF-OprN, MexCD-OprJ, and MexXY-OprMin(18).

Quantitative RT-PCR assay analyzed the mRNA expression of *norA* and compared its expression with isolates without treatment (control), isolates were exposed to azithromycin antibiotic, and also were exposed to synthetic inhibitors. The result of gene expression was shown in table (4). The fold of gene expression of the *norA* gene for active efflux in the isolates of S. aureus studied was (4.61), this result was higher than the fold of nonactive efflux *norA*gene (2.14). The fold of gene expression in isolates exposure to azithromycin was higher than isolates untreated group(control). The fold of gene expression of PAβN was 0.73 for active efflux and for nonactive efflux the fold was 0.40, alsoin isolates that exposures to Phenothiazine fold was 0.87 for active efflux, while for (nonactive) the fold was 0.84 and this results of synthetic products was less than the fold of isolates without treatment group. These results showed that the synthetic products decreased chromosomal efflux pump *norA* gene expression. On the other hand,the above results demonstrate the significant gene expression in isolates exposed to antibiotics.

MDR efflux pump of S. aureus is possessed high resistance to antibiotics, including resistance to b-lactams, aminoglycosides, macrolides, lincosamides, fluoroquinolones, chloramphenicol, sulfonamides,streptomycin, and tetracycline(19). Thioridazine, Phe-Argβ-naphthylamide (PAβN), or the arylpiperazine NMP are some of the compounds categorized were used as efflux pump inhibitors(20).

Table (4) Fold of *NorA* expression Depending on $2^{-\Delta Ct}$ Method

Groups	Isolate	Fold of gene expression
Azithromycin	C+D	2.14
	A+B	4.61
PABN	C+D	0.40
	A+B	0.73
Pheno	C+D	0.84
	A+B	0.87
Untreated (Control)	C+D	1.0
	A+B	1.0

Conclusions

Our study confirmed the important role of efflux pumps in high-level resistance of *Pseudomonas aeruginosa* and *Staphylococcus aureus*isolates, hence the intrinsic resistance to antibiotics of some isolates may

return to their efflux systems. Phe-Arg β-naphthylamide (PAβN) potentiated antibiotic activity through inhibiting *mexR* efflux pump in *P. aeruginosa* and *norA* efflux pump in *S. aureus.*

Distinguish between Two Species of *streptococcus* by *sk* gene

Rawaa Kh. Mohammed[1], Harith K. Buinya[2]

[1]M.Sc. Student, [2]Assist. Prof., Department of Biology/College of Education for Pure Sciences/ University of Anbar/Anbar-IRAQ

Abstract

This study aims at the possibility of using the *sk* gene encoding the Streptokinase protein to differentiate between the different species belonging to the genus *Streptococcus* which can produce this protein., 12 bacterial isolates belonging to the genus *Streptococcus* were obtained, and by using thecaseinolytic assay test, all the studied isolates gave a positive result with different clear zone diameters around the wells. DNA was then extracted from the isolated bacteria and used as a template for the amplification of the *sk* gene using specific primers for the gene. The 1300 bp was amplified as PCR product comparing them with the DNA ladder. The target gene was obtained from of *S. pyogenes* and *S. dysgalactiae subsp. equisimilis*. . The result was confirmed by identifying the gene sequences and comparing it with the database in NCBI, which showed a similarity of more than 98% and the percentage of similarity between the genes of the different species was more than 99%. The *sk* gene for both species were digested with *Btg*ZI and *Mbo*II restriction enzymes. The results of the agarose gel electrophoresis showed that the gene belonging to the *S. pyogenes* possesses restriction sites for *Btg*ZI restriction enzymes that differ in location from that of *the S. dysgalactiae subsp. equisimilis*. Where the bundles appeared in different locations, which means that the location and number of restriction sites differ between the two types, and this feature can be used to differentiate between them.

Keywords: *Sk gene, Streptokinase, Streptococcus.*

Introduction

In view of the many changes occurring in the patterns of life, whether social or economic in general, in the world, an increase in the rates of many coronary heart diseases, caused by blood clotting in the arteries of the heart, which sometimes leads to death, has been observed. It leads to the stopping of blood circulation, in the physiological state, fibrin and platelets are used for clotting to prevent blood loss during injuries in a process called blood clotting]1[. Because of the high economic cost of tissue plasminogen activators, it was necessary to using the low expensive and more available, and since there are some bacterial species also have the ability to produce proteins play role as a plasminogen activators like Streptokinase and Staphylokinase]2[. The pathogenic bacteria differ in seriousness Infecting humans and animals according to the virulence factors they produce, so work has been made to convert the most dangerous virulence factors to humans and animals into effective compounds that can be used in the treatment of many diseases through the use of genetic engineering techniques[3]. An important virulence factor in causing hemolysis, which is secreted by some bacterial species, is the streptokinase protein (SK) produced by some types of hemolytic streptococci of the genus Streptococcus, as it has been used as a treatment in dissolving blood clots as in cases of myocardial infarction since 1959 and in the treatment of Peripheral arterialocclusive since 1974 and is now widely used in many countries of the world]4[.

The streptokinase protein encodes for the *sk* gene, which has a size of 1.3 k bp]5[. it was first isolated in 1933 from a Streptococcus broth culture and named Streptococcal fibrinolysin]6[. The term Streptokinase was used for the first time in 1945, and the amino acid sequence was fully determined by Jackson and Tang]7[. It is an extracellular protein secreted by hemolytic streptococcus bacteria (GAS), (GCS) and (GGS). It is a single-chain protein consisting of 414 amino acids with a molecular mass of 47 kDa that has the ability to bind to plasminogen and form a streptokinase - plasminogen complex. This complex turns plasminogen into active plasmin that breaks down fibrin, which is the main protein for blood clots]8[.SK is not in itself a plasminogen activator, but rather binds to free-circulating

plasminogen or with plasmin to form a complex that can convert another plasminogen into a plasmin[9].

The aim of the study was to differentiate the different types of Streptococcus bacteria using the *sk* gene.

Materials and Method

Samples Collection: Bacterial isolates were collected from the laboratories of Al-Amiriya General Hospital (Al-Anbar) and the educational laboratories in the City of Medicine (Baghdad), from various pathological conditions (Table 1). The isolated diagnosis by Biochemical test[10,11] and confirmed with the Vitek-2 Compact.

Table (1) Types and numbers of bacteria isolated and belonging to the genus Streptococcus.

No. of isolates	Isolates	
1	Streptococcus pneumoniae	1
2	Streptococcus agalactiae	2
5	Streptococcus mutans	3
1	Streptococcus suis	4
2	Streptococcus pyogenes	5
1	S.dysgalactiaesubsp. equisimilis.	6

The ability of bacteria to produce Streptokinase: To find out the ability of bacteria to produce streptokinase, a caseinolytic assay test was used. Broth culture of 18 hr. isolates was prepared. 1 mL of bacterial culture was taken from each culture and placed in a 1.5 ml Eppendorf tube. The cells were sonicated with an ultrasound machine and a portion of the shattered culture was used in caseinolytic assay. Mix 36 ml of buffer solution (mMTris- HCL/150 mMNaCl) with 400 mg of agarose and after dissolving by heat add 2 ml of skim milk with 1 ml of blood plasma. It was mixed well and was poured into a petri dish. Well of 5 mm was made in the plate and 50 microliters were loaded from each sonicated culture in the well and incubated for 18 hours at 37 ° C. the clear zone around the wells was measured[12].

Chromosomal DNA extraction: DNA was extracted from various types of *Streptococcus* bacteria by (Genomic DNA extraction kit) from Geneaid Company. Process was done according to the instructions of the provider. Electrophoresis was carried out using a 1% agarose gel, where the samples were carried over with a voltage difference of 100 millivolts for an hour, and the DNA was investigated by exposing it to a UV-transilluminator with a wavelength of 256 nanometers.

Gene amplification and Purification: The *sk* gene was amplification by Polymerase Chain Reaction (PCR) using DNAisolated from bacterial isolates using specific primers for *sk* gene (Forward:GGGA TTCCATATGATTGCTGGACCTGAG). (Reverse: CCGGAATTCTTATTTGTCTTTAGG) [13].

The PCR device was programmed according to the steps taken by Bustin, 2004, after which an electrophoresis was performed using agarose gel at a concentration of 1.2% to read the products of the PCR reaction. Then, Purification was done using Gel/PCR DNA Fragments Extraction Kit .To purify the polymerase chain reaction products of the *sk* gene, the purification process was done according to the instructions of the provider.

Gene Sequencing: The PCR product were sequenced in Macrogen company(South Korea) using a Genetic Analyzer to obtain the gene sequences. The data were analyzed by Mega 7 software and compared with Ref. sequences which published inNCBI.

Restriction Enzyme: The restriction enzymes (*BtgZI* and *MboII*) were procured from NEBI (USA) and used according to the instructions of the supplying company**.**

Results and Discussion:

Caseinolytic assay test: Table (2) and Figure (1) show the results of the caseinolytic assay for Streptokinase activity after 18 h incubation at 37°C.

Table (2) Dimensions of dissolution in caseinolytic assay test for isolated bacteria

	Isolate	Diameter of zone
1	Streptococcus pneumoniae	6mm
2	Streptococcus agalactiae	10mm
2	Streptococcus agalactiae	12mm
4	Streptococcus mutans	11mm
5	Streptococcus mutans	14mm
6	Streptococcus mutans	15mm
7	Streptococcus mutans	9mm
8	Streptococcus mutans	12mm
9	Streptococcus suis	15mm
10	Streptococcus pyogenes	5mm
11	Streptococcus pyogenes	6mm
12	S.dysgalactiae subsp.equisimilis	9mm

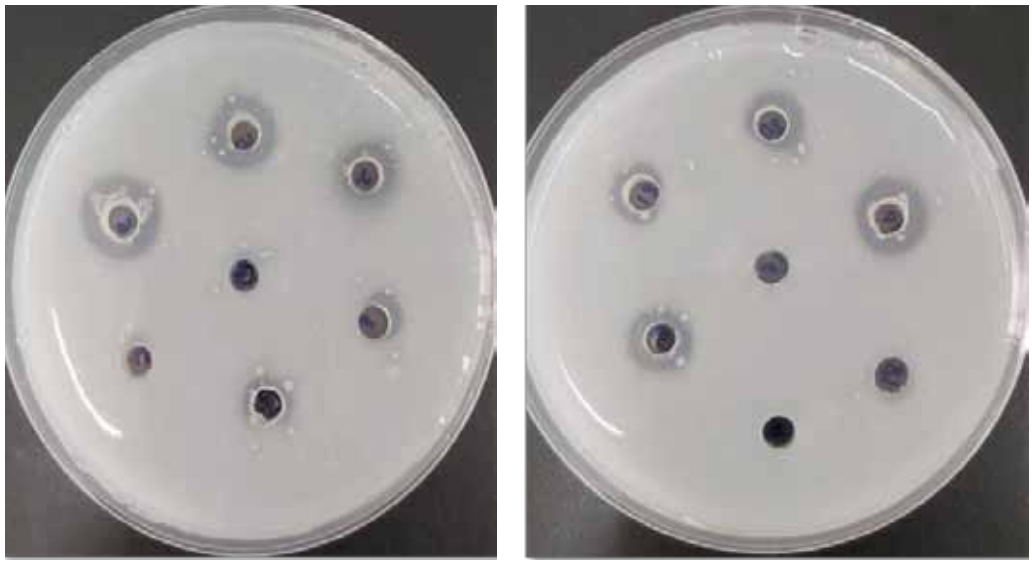

Figure (1): The result of caseinolytic assay and transparent area formation around the wells.

Chromosomal DNA extraction: The agarose gel electrophoresis at a concentration of (1%) showed the emergence of a single bund representing the chromosomal DNA of the different species of the Streptococcus genus, which was detected using ultraviolet radiation and an ethidium bromide stain (Figure 2).

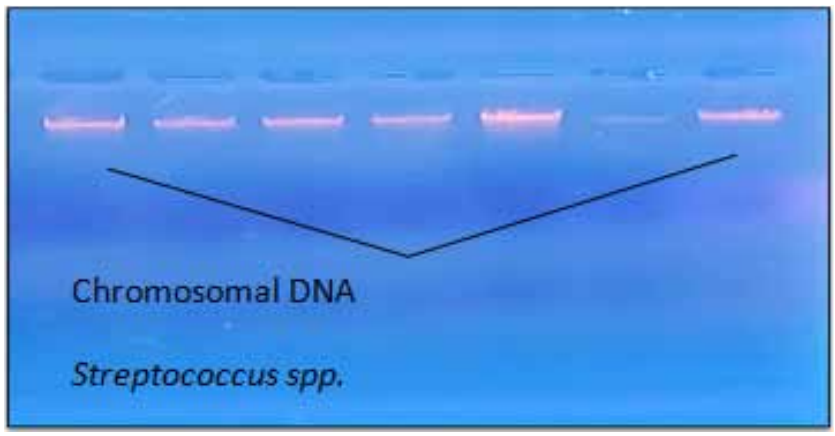

Figure (2): Agarose Gel Electrophoresis (1%, 100 V/cm/60 min.) for Chromosomal DNA extracted from different species of *Streptococcus* bacteria.

Gene amplification and purification: The results showed that the targetgene was obtained from three isolates: *Streptococcus pyogenes*, *Streptococcus pyogenes* and *S.dysgalactiae subsp.equisimilis*. As for the other isolates, the reaction was carried out more than once, but the target fragment of the gene was not obtained even though the isolates gave a positive result in the caseinolytic assay test. The reason for not obtaining the *sk* gene from the rest of the bacterial isolates may be attributed to the fact that the isolates may not possess the gene because they are not affiliated with the blood-analyzing bacterial strains of the Lancefield groups A, C, G.

Since the isolates in which the gene was isolated belong to the aforementioned bacterial strains and are of type A, C, and G, then this study is identical to previous studies, as all of them confirmed that all hemolysis bacterial strains belonging to the mentioned types contain the gene encoding to produce Streptokinase[15],[16],[17].

Then, the process of purification of the polymerase chain reaction products of the *sk* gene was carried out using a Gel/PCR DNA Fragments Extraction Kit and electrophoresis on a 1.2% agarose gel for one hour and detected under ultraviolet irradiation and the ethidium bromide, the following result showed in figure (3) .

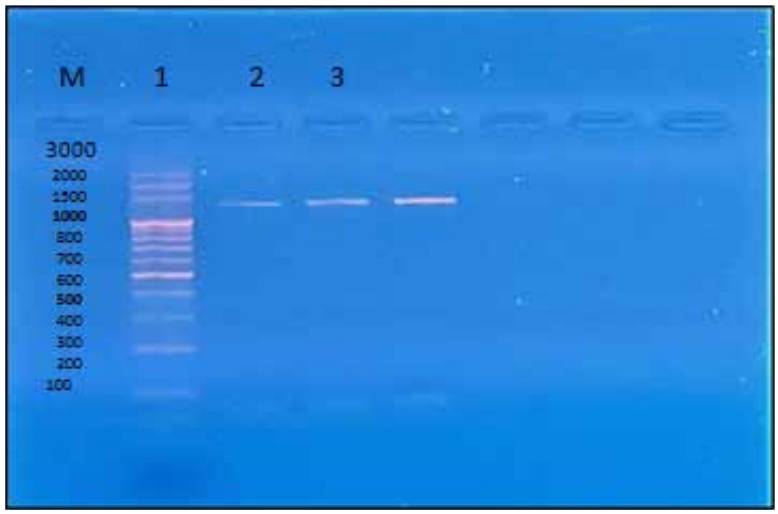

Figure (3): Gel Electrophoresis (1.2%, 100 v/cm/60 min) for PCR products for the Streptokinase encoded *sk* gene after gene purification using a Gel extraction kit. M: 100 bp DNA marker 1 : *S. pyogenes* 2 : *S. pyogenes* 3 : *S. dysgalactiae subsp. equisimilis*

***sk* gene sequences:** The PCR products were sent to Macrogen in South Korea, to determine the nitrogen base sequences of the DNA fragment of 1300 bp by the Sanger and Coulson method, or called the chain termination method. The results obtained from the company were then matched with the database at the National Center for Biotechnology Information (NCBI). The similarity between *sk* gene and their counterparts in NCBI were more than 98% for both species.

A comparison was also performed between the *sk*gene sequences of *S. pyogenes* and *S. dysgalactiae subsp. equisimilis* using the Mega 7 program, and the result was almost 99%.

Restriction Enzyme: The result of electrophoresis of the *sk* gene of *S. pyogenes* and *S. dysgalactiae subsp. equisimilis* . After treatment with the Restriction enzyme *BtgZI*, there was a difference in the position of the bundles on the agarose at a concentration of 1.5%. . This gives an indication that the location of the *BtgZI* Restriction enzyme sensitive sequence in the gene belonging to the *S. pyogenes* is in a different location on the gene map than the location of the sensitive sequence for the same enzyme for the gene belonging to *S. dysgalactiae subsp. equisimilis.* The size of the DNA fragment removed from the gene in the *S. dysgalactiaesubsp. equisimilis* was larger than the size of the fragment of DNA that was removed from the gene of S. pyogenes after being treated with the restriction enzyme Figure (4) .

When the *sk* gene was treated with the *MboII* restriction enzyme for both types, there was no apparent difference in the size of the gene after treatment, and this may be due to the fact that the electrophoresis on the agarose gel does not give clear separation of the bundles of DNA segments with a difference of less than 50 bp[18]. Therefore, the use of vertical electrophoresis with SDS gel is better to separate DNA fragments whose size difference is less than 50 base pairs.

By reviewing the studies on the *sk* gene, we did not find any study indicating the possibility of differentiating the different types of the *Streptococcus* by treating the sk gene with restriction enzymes despite the presence of susceptible sites for many restriction enzymes in the gene sequences recorded in NCBI. Through our current study, it became possible to distinguish between the different species belonging to the genus *Streptococcus* through the *sk* gene after treatment with restriction enzymes.

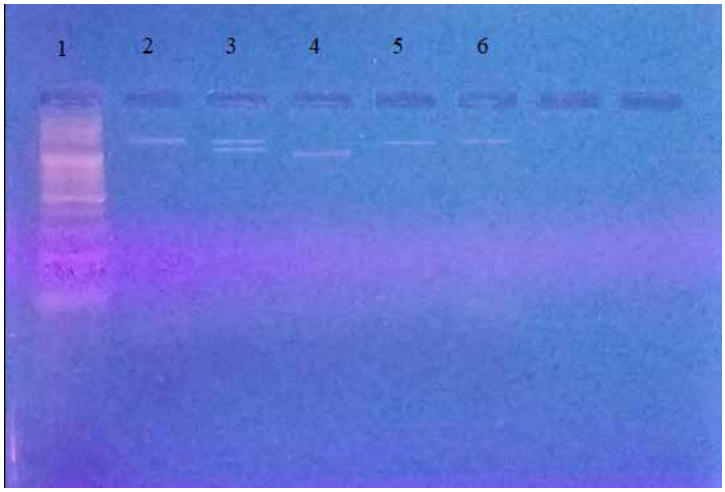

Figure (4) Agarose Gel Electrophoresis (1.5%, 100 v/cm, 60 min.) for*sk* gene restricted by*BtgZI* and *MobII* Restriction Enzymes at a concentration.

1-100 bp DNA Ladder 2- The *sk* gene is not treated with restriction enzymes 3-*sk*gene for *S. pyogenes* treated with *BtgZI*4- *sk*gene for *S. dysgalactiae subsp. equisimilis* with *BtgZI*5- *sk*gene for *S. pyogenes* with *MboII*6- *sk*gene for *S. dysgalactiae subsp. equisimilis* with *MboII* .

Conclusions

The results of the detection of the *sk* gene in beta-hemolytic bacterial isolates belonging to types A, C, and G are consistent with the results that all hemolysis bacterial strains of the aforementioned species contain the gene encoding the production of Streptokinase. Also, all of the studied Streptococcus isolates gave a positive result of the caseinolytic assay test, and this may give an indication of the presence of proteins having similar activity to that of Streptokinase. It was also found that the sequences of the *sk* gene were identical to what was published in the NCBI database at a rate of more than 98%, and at the same time, the sequences of the same gene belonging to two different species had a difference of less than 0.5%. The *sk* gene contains sensitive sites for many restriction enzymes, through which it was possible to distinguish between the different strains of the Streptococcus genus through the *sk* gene after treatment with the *BtgZI* restriction enzyme.

Impact of Vitamin D Elements in Insulin Sensitivity in Type 2 Diabetes Mellitus (DM2)

Wafaa Raji Alfatlawi[1], Zainab Majid Ali[2], Muhammed Abdul-Gabar Aldabagh[3]

[1]Assist Prof., [2]M.Sc. Student, University of Technology, Baghdad, Iraq, Applied Science Department, Applied Chemistry Science, 3Assist Prof., Al-Nahrain University, Baghdad, Iraq, College of Medicine, Medical Research Unit

Abstract

Numerous non-skeletal diseases have been reported to be associated with vitamin D status including type2 diabetes mellitus (T2DM). Different studies provide evidence that vitamin D status as well as other elements such as vitamin D binding protein (DBP) and vitamin D receptor (VDR) may play substantial role in glucose tolerance. Present study was designed to investigate the role of vitamin D status and their elements in insulin resistance or sensitivity in T2DM patients Current study includes 84 participants of both gender (56 patients and 28 as control). Clinical samples were collected from clinically proved DM2 patients. Serum levels of insulin, FBS, VD, VDR, and DBP were measured of each subjects. Using of Homeostasis Model Assessment Insulin resistance (HOMA-IR), T2DM patients were sub grouped to insulin resistance (IR) and insulin sensitivity (IS) groups. Relations among studied factors, FBS showed significant positive and negative relation with HOMA-IR and VD3 respectively, furthermore HOMA-IR revealed significant positive relation with DBP and VDR. Also, DBP revealed significant positive relation with each of VDR and HOMA-IR. On the other hand, VD3 levels showed significant and non-significant elevation in IS group compared to C and IR group respectively, while DBP revealed significant and non-significant dropping in IS group compared to C and IR groups respectively. Levels of VDR in IS group showed significant dropping compared to C and IR groups respectively. Our study concludes that VD3 alone or with its elements play substantial role in regulation of blood sugar levels particularly related to insulin sensitivity.

Keywords: *T2DM, Vitamin D elements, HOMA-IR.*

Introduction

Diabetes mellitus is a chronic disorder that affects several populations among the whole world and it is regarded as a widespread health problem[1]. Diabetes also affects individuals of different ages and health status, as it affects the rich and poor, men and women, as well as adults and children, and it is a disease that has sufficient capacity to destroy the body[2]. Also, diabetes is caused by an imbalance of hormones such as insulin and glucagon, which are the hormones responsible for regulating the level of glucose in the blood in order to stabilize the level of glucose[3].

Since there is scientific evidence on the relationship between the deficiency of VD3 levels and diabetes, people at risk of diabetes should be examined for low VD3 levels to improve their health in the long run, as vitamin D deficiency is linked to high blood glucose, insulin resistance, high blood pressure, and heart disease[4].

Deficiency of vitamin D was found to have the principal role among insulin resistance. Hence, there may be a risk of developing diabetes. Many studies have explained that vitamin D deficiency plays a role in insulin deficiency, and it is closely linked to an inherited polymorphism, including the protein associated with vitamin D (vitamin D binding protein (VDBP), the vitamin D receptor (VDR), and the alpha-hydroxylase gene vitamin D1. All of these measures work to balance glucose in addition to mediating insulin sensitivity. There is an evidence explores the relation between VD3 case and insulin resistance, but further discoveries are required. From those evidences, it is clear that VD3 plays an important role in the molecular processes of

synthesis, secretion as well as the peripheral sensitivity of insulin [5].

The pathophysiology of T2DM development, which plays the role of insulin resistance in muscle and liver cells, can be mentioned here, which means weak insulin signal given to cells, resulting in decrease in the glucose uptake and increase in the output of hepatic glucose, accompanied by failure of beta cells in the pancreas for producing enough insulin in order to maintain normal levels of glucose in blood and to prevent releasing of adipose fatty acids [6].

VDR are expressed by the pancreatic cells, human skeletal muscle as well as adipose tissue that are the main elements of peripheral insulin sensitivity[7].

The present study was designed for investigating the effects of vitamin D elements as VDR andV BDP in insulin sensitivity in development of type 2 diabetic patients.

Materials and Method

In this study, 84 participants of both gender (56 patients and 28 as control). Clinical samples were collected from patients who were clinically proved with T2DM. From patients and control subjects, in fasting state by venipuncture, using a 5ml syringe between 8 to 9 A.M, 3 ml of blood were obtained and dispensed in a plain tubes and left for hour to clot at room temperature (22ºC). Then, it was centrifuged at 3000 rpm for 10 minutes to collect serum . The serum was divided in to aliquots in eppendorff tube for measuring the (VD3, VDR, VDBP, FBS, and Insulin). Estimation of serum levels of vitamin D3, VDR, DBP, and insulin was done using the commercial ELISA kit of Sun long/China, in addition to measuring of serum levels of fasting blood sugar (FBS) using Biolab Glucose kit.

Statistical analysis was done using SPSS (Statistical Packages for Social Sciences- version16).

Table (1) Patients and control classified according to HOMA model

Factor	C M±SD	IS M±SD	IR M±SD		P-value	
HOMA-IR	1.231±0.409	2.058±0.527	3.65±1.229	C:IS	C:IR	IS:IR
				0.000	0.000	0.000
Insulin (mU/L)	5.576±1.849	4.594±0.936	6.391±2.046	0.020	0.072	0.000
FBS (mg/dl)	89.308±8.957	184.72±42.415	234.076±54.922	0.000	0.000	0.000

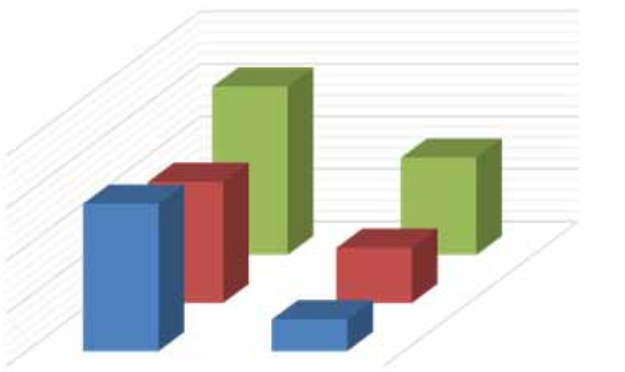

Figure (1) Patients and control classified according to HOMA-IR model.

Results and Discussion

Table (2) and Fig (2) show the mean of VD3 in studied group. There was highly significant difference between C and IS patient group (20.118±9.371), (28.481±7.909), p-value (0.004) respectively . While there was non significant difference between C and IR patient group (20.118±9.371), (25.666±10.416), p-value (0.07), also there was non significant difference between IS and IR patient group (28.481±7.909), (25.666±10.416), p-value (0.361) respectively.

Table (2) Show the mean VD3 in studies group:

Factor	C M±SD	IS M±SD	IR M±SD	P value		
				C: IS	C: IR	IS: IR
VD3	20.118±9.371	28.481±7.909	25.666±10.416	0.004	0.075	0.361
DBP	0.47±0.255	0.394±0.14	0.582±0.226	0.152	0.050	0.001
VDR	2.082±0.975	1.644±0.394	1.905±0.772	0.026	0.979	0.024
FBS	89.308±8.957	184.72±42.415	234.076±54.922	0.000	0.000	0.000
HOMA-IR	1.231±0.409	2.058±0.527	3.65±1.229	0.000	0.000	0.000
INSULIN	5.576±1.849	4.594±0.936	6.391±2.046	0.020	0.072	0.000

Insulin sensitivity and insulin resistance are two aspects of the same coin, meaning that decrease the body sensitivity to insulin means presence of insulin resistance. Whereas insulin resistance is harmful to the body health, insulin sensitivity is advantageous[5]. Vitamin D deficiency can be the reason for imbalance of glucose and also can play a role in insulin resistance as well as the.

T2DM pathogenesis, via its impacts on both β-cell function and insulin sensitivity. It was found that vitamin D deficiency could affect insulin resistance throughout different mechanisms involving the increase in related pro-inflammatory cytokines as well as acute phase reactants. So, correction of VD3 levels help in regulation of insulin secretion from the pancreatic beta cells[8]. This results disagree with the results of Tee garden & Donkin[9] who found that serum concentration of VD3 status, has been related with improved glucose homeostasis and increased insulin sensitivity. The supposed effect of VD3 on insulin sensitivity might be via increasing the muscle mass that could enhance the insulin sensitivity within whole body.

Nag pal et al.[10] has revealed that VD3 supplementation could possibly affect the peripheral insulin sensitivity.

Numerous studies have revealed the effect of VD3 supplementation on glucose homeostasis. It was revealed that insulin resistance appeared to be diminished in patients with T2DM who had received VD3. Gagnon et al.[11] showed an improvement in insulin sensitivity by increasing the concentration of 25 (OH)D in serum.

In the present study, a significant negative correlation was found between VD3 and fasting blood sugar (FBS) as (p-value = 0.041) indicating that VD3 deficiency is significantly correlated to increasing the fasting blood glucose levels which helps in predicting T2DM. The findings of this study agree with the findings by Mackawy & Badawi, have detected a significant negative correlation between vitamin D levels and FPG (p-value=0.036), insulin levels and HOMA-IR (pvalue=0.563)[12].

Table (2) and Fig (2) show the mean of VDBP in studied group . There was non significant difference between C and IS patient group (0.47±0.255), (0.394±0.14),p-value (0.152) respectively . AS well as there was significant difference between C and IR patient group (0.47±0.255), (0.582±0.226),p-value (0.050), also there was highly significant difference between IS and IR patient group (0.394±0.14), (0.582±0.226), p-value (0.001).

Identification of VDBP levels in serum is valuable in understanding the diabetic state[13]. Fawzy & Beladi[14] have studied the correlation between circulating VD3, DBP, and VDR expression and the diabetic nephropathy severity in a group of Saudi population with T2DM. It was found that serum levels of VDBP were significantly increased in the whole patient groups.

Ashraf et al.[15] have conducted a study to investigate relations between the total, free, as well as the bioavailable 25(OH) D and vitamin DBP in addition to evaluating the correlations of vitamin VDBP with insulin resistance indicators. From that study, it was suggested that concentrations of VDBP were controlled by total 25(OH)D levels for maintaining suitable concentrations of bioavailable 25(OH)D. Also, there was an inverse correlation between VDBP concentrations and insulin resistance.

Table (2) and Fig (2) show the mean of VDR in

studied group . There was significant difference between C and IS patient group (2.082±0.975), (1.644±0.394), p-value (0.026) respectively . On the other hand there was non significant difference between C and IR patient group (2.082±0.975), (1.905±0.772), p-value (0.979), While there was significant difference between IS and IR patient group (1.644±0.394), (1.905±0.772), p-value (0.024) respectively.

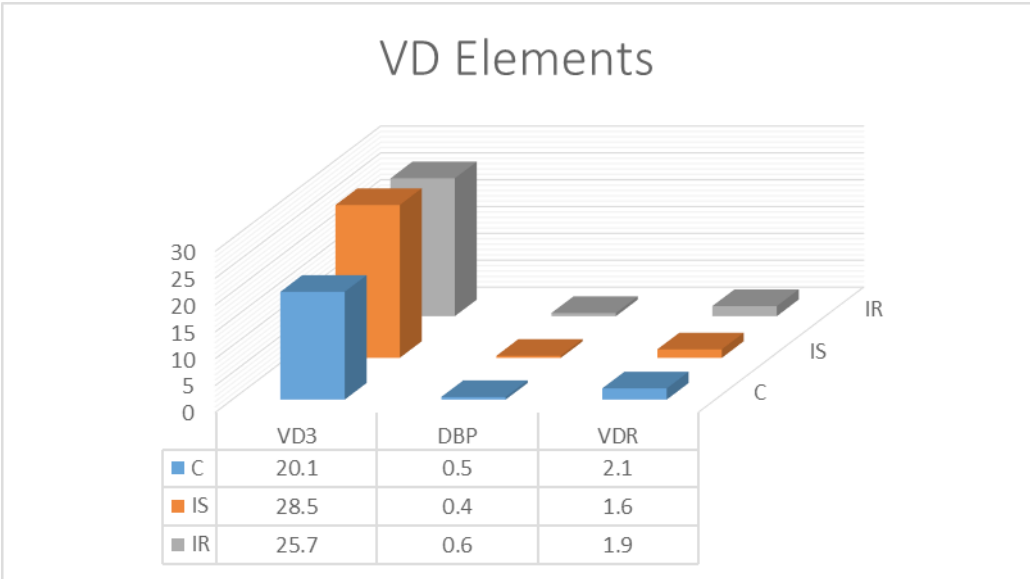

Figure (2) VD3 in studies group

Similarly, there was statistically significant differences between the means of HOMA-IR according to C group, IS group, and IR group = (1.231±0.409, 2.058±0.527, and 3.65±1.229, respectively) and p-value for all = (0.000).

The assesses of HOMA-IR as well as fasting insulin were found to be reduced with high levels of 25(OH) D[16]. The findings of this study have revealed a negative correlation between HOMA-IR and VD 3, although it was non-significant (p-value= 0.563). The findings of the current study agree with chun et al [17] who has conducted a study on Chinese people with T2DM, and he found a negative correlation of IR and the related biomarkers with 25(OH)D status. Similarly, an inverse correlation of IR with 25(OH)D concentration has been detected for values of 25(OH)D between (16-36) ng/ mL[17].

Correlation between parameters: There was positive non significant correlation between VD3 with VDBP (p-value=0.318),also there was positive non significant correlation between VD3 with VDR (p-value=0.432),Also there was negative significant correlation between VD3 with FBS (p-value=0.036), Aswell as negative non significant correlation between VD3 with HOMA-IR(p-value=0.563), On the other hand there was positive non significant correlation between VD3 with insulin (p-value=0.276).

Table (3) Correlation between vitamin D3 and different parameters:

Item		VD3	DBP	VDR	FBS	HOMA-IR	Insulin
VD3	Pearson Correlation	1	.108	.085	-.223*	-.062-	.117
	Sig. (2-tailed)		.318	.432	.036	.563	.276
	N	88	88	88	88	88	88
DBP	Pearson Correlation	.108	1	.771**	-.027-	.424**	.743**
	Sig. (2-tailed)	.318		.000	.801	.000	.000
	N	88	88	88	88	88	88

Item		VD3	DBP	VDR	FBS	HOMA-IR	Insulin
VDR	Pearson Correlation	.085	.771**	1	-.088-	.368**	.737**
	Sig. (2-tailed)	.432	.000		.415	.000	.000
	N	88	88	88	88	88	88
FBS	Pearson Correlation	-.223*	-.027-	-.088-	1	.722**	-.049-
	Sig. (2-tailed)	.036	.801	.415		.000	.648
	N	88	88	88	88	88	88
HOMA-IR	Pearson Correlation	-.062-	.424**	.368**	.722**	1	.598**
	Sig. (2-tailed)	.563	.000	.000	.000		.000
	N	88	88	88	88	88	88
Insulin	Pearson Correlation	.117	.743**	.737**	-.049	.598**	1
	Sig. (2-tailed)	.276	.000	.000	.648	.000	
	N	88	88	88	88	88	88

Conclusion

From this study, it is concluded that, there is a relation between VD3 either alone or with its elements as VDBP and VDR, play a significant role in regulation of blood sugar levels particularly related to insulin sensitivity.

Angina and Sudden Fatal (Arrhythmia) Cardiac Disorders that affect People with the Presence of Risk Factors that Show a Change in the Electrical Conductivity of the ECG

Salah Abd-Al Kader Omran

Assist. Prof., M.Phil. Med. Cardiologist, Al-Muthanna University, College of Medicine, Iraq

Abstract

The work was from realistic academic applied practice for research in the General Teaching Hospital/ Specialized Center for Chronic Diseases and Diabetes Mellitus on a group of patients in the city of Samawah-Iraq for the period (2019-2020). The total number of patients is (1250) patients divided (500 young men of both sexes) (and women are 350 patients after 50 years old) (and men 400 patients after 50 years) the research focused on heart disorders) arrhythmia) That threaten human life, especially in a middle-income country, and the detection and strengthening of medical capabilities and reduce deaths and the occurrence of sudden death, the work was focused on arrhythmia, And to the different heart diseases that help their emergence, to the real causes that arise from them (exocardil and endocardil) and to the calculation of the formula that calculate the pulse, respiration, oxygenation, cardiac output, blood pressure and the number of arrhythmia (heart disorders) per minute, hour or day, in addition to laboratory and radiological analyzes, Physical examination and the formation of a scientific formula, and we have adopted three important strategies in our work.. Cases decreased arrhythmia By controlling basic heart disease, the primary treatment is the major disease that causes it arrhythmia According to its cardiac or extra cardiac origin, the mortality rate decreased, in emergency cases and resuscitation (I.C.U) because of AF, in general and critical cases, the cost of treatment and health for the patient and for the state has decreased and the types arrhythmia, It was completed according to the program and the used treatment protocols.

Introduction

Introduction

The main objective is the early control of cardiovascular diseases, especially the Arrhythmia, and their types that cause sudden cardiac death (SCD) before and after angina pectoris and the chronic diseases that accompany them and which contribute greatly to the development of the Arrhythmia and irregular heartbeat that affects young people and the elderly without discrimination, and we contribute to the calculation and equation of cardiac changes and finding ways Therapeutic treatment for preventing and treating heart disorders.

Due to the rise in cardiovascular diseases that cause the death of many people, especially in the country of Iraq, the focus and work was on the most basic problems as a result of the violent conflict of life, pollution, wars, their remnants, and the various risk factors surrounding the place, where a third of men and a quarter of women die of ischemia heart disease and their stroke [1] A group of signs appear that shows lack of access to the necessary amount of oxygen to the heart muscle crossing it, and they constitute a clinical syndrome, not a disease[6]. It may occur when there is an imbalance between the delivery and required oxygen supply to the heart muscle. Coronary stenosis and sclerosis are the most common cause of angina pectoris .. and associated cardiac disorders (Arrhythmia): Arrhythmias are a disturbance in the electrical rhythm of the heart. Arrhythmia is often a manifestation of structural heart disease, [2,3] but it may also occur in the normal heart context. Symptoms are more likely to occur if the arrhythmia is associated with the maximum heart rate.[5] An arrhythmia can cause palpitations, dizziness, fainting, chest tightness,

or shortness of breath, and it can lead to heart failure or even sudden death.) Which forms the focus and the bulk of our research Knowing the real causes of death, the concrete results, the pathological anatomy, and the correct direction for doctors to study the cases by using the method to reduce them before and after the angina when it occurs, or the various chronic diseases that cause sudden cardiac arrest, therefore treatment and prevention strategies [22] have been returned to undergo strict evaluation based on the rule, evidence and evidence in clinical work And academically, it is useful to immediately recognize and protect people before most people are affected by various causes and from the transition of coronary artery disease and other diseases to an advanced stage, Before noticing the patients who have symptoms, but some of the people do not have a complaint, but the risk factors are present and they are ready for infection in addition to their family history, and the patients who show symptoms and periodically review the hospital and they have a file we have under control all according to the degree of severity, our main goal Protecting the patient from sudden heart attacks that do not distinguish between the young and the elderly,[4,8] especially after cardiac conditions that cause systolic arrest, ventricular arrhythmia, tremors, mechanical heart loss, and insufficient blood flow to the heart. We approved early clinical diagnosis, in addition to laboratory and radiographic, ECG,[9,10] Eco-cardiograph, cardiac –Angiography coronary, Halter, treadmill test ., cardiac stress test, cardiac catheterization PCI (Angioplasty) and ICD (pacemaker –implantable cardiac defibrillator) . And in cases that require immediate resuscitation, because the patient is exposed to unconsciousness and pulse, breathing may take some time to stop completely after cardiac arrest. Physical death is unless immediate treatment is provided to him[11] The cause of sudden cardiac death (SCD) is usually the development of catastrophic heart disorders. AF (atrial fibrillation) And the most dangerous VF (vertical fibrillation And all the Arrhythmia in which lack of follow-up, initial medical advice, and coronary artery patients are the most common due to the risk factors surrounding the patient (high blood pressure, lifestyle, dietary behavior, increased cholesterol and triglycerides, atherosclerosis and diabetes mellitus,stares, Obesity and medications) The angina is stable or unstable, which develops myocardial infraction (MI) damage into the heart (necrosis) (STEMI, NSTMI),[12] That is why we were very interested in arithmetic, because it is one of the most common causes of death, Among the most famous of them are the arthritic according to the division of the pulse (Tachycardia, Bradycardia) and its various forms, but people may not feel symptoms, That lead sudden cardiac death (SCD) About 80% (VF) The patient may lose consciousness and die, But there are many types of Arrhythmia, The disease may not feel symptoms Just Heart palpitations, And pulse upon palpation pose line, Of different ages, but the most common in the elderly, VF, AF and those who highlighted the risk disorder .[17,21] And on the high importance of studying future cases in outpatient clinics and emergency .. We find that most of the people who have Arrhythmia 25% are treated with a digitalis medicine that comes to them by Arrhythmia-who are subjected to general anesthesia 50 % Are exposed to Arrhythmia, and 80% to patients after Acute Myocardial Infraction.[14] And neurological conditions that acute as coronary artery spasm (prinzmetal s" angina (vasospastic), in addition to anti-depressant drugs, and congenital malformations of the heart,[7,15] but the most famous and most severe cases

Table (1): Of the most famous and most reasons that lead Arrhythmia

No.	The main reason	Results
1.	Heart attack (myocardial infarction)	Part of the heart gets to him damage .
2.	Change in heart structure	Change in the shape of the heart valves, cardiac enlargement, cardiac aneurysm .
3.	Coronary artery disease	Coronary artery stenosis or blockage.
4.	Smoking and stress	Be the cause of the Arrhythmia .
5.	Drinking too much alcohol or caffeine	Possible reason Arrhythmia .
6.	Drug abuse and electrolytes imbalance	Possible change in electrolyte balance .
7.	Certain medication (such as digitalis)	Some medicines like, digitalis, anti-depressant, Erythromycin, clarithromycin, pentamidine, moxifloxacin, levofloxacin.
8.	Overactive thyroid gland (hyperthyroidism) or Hypo secretory (hypothyroidism)	Some patients have an overactive thyroid gland (tachycardia) or hypothyroidism (Bradycardia)

A heart rate of more than 100/minute is called a tachycardia and a heart rate of less than 60/minute is called a bradycardia . [16,19] But not all tachycardia or bradycardia means that he has a problem, for example, during exercise, stress and muscle exertion, There are doctors who differed in the division Arrhythmia ..But the most common and the most famous are types Arrhythmia, It is the University of Oxford, and we will only talk about the most famous, most frequent and their effects on the heart in the research:[18,20]

Materials and Method

The work was done based on the data and what were caused by heart disease disorders, the academic clinical work was done in the Teaching Hospital/and the Specialized Center for Chronic Diseases and Diabetes in the city of Samawah - Iraq for the period (2019-2020) to collect the largest number of patients and the disease history of different ages(Young men of both sexes 500), women 350 patients after the age of 50 years (and men 400 patients after the age of 50 years) randomly from different segments of society 1250 patients The main goal was to reduce and maintain early angina pectoris and accompanying cardiac disorders And to protect against sudden cardiac arrest, the act was to prevent angina pectoris and malignant heart disorders) rhythm, Rate) that develop without the patient's awareness. - Therefore, the formula was calculated :

The rate of Arrhythmia = number of Arrhythmia in (ECG) x Time (minute, hour, day)

And the calculation of the quantity and times and their type come in the form of repeated or continuous shifts and how many are the number, if there are more than 10 per hour it is considered a disease condition (Extrasystoles, any type of Arrhythmia or persistent) is determined with its quality, It means normal breathing per minute from 12 to 16, i.e. the number of breaths per minute x 4 beats. To help us to determine the quality of breathing and pulse, and calculate the

Volume of blood per minute= =[Heart rate x stroke volume] 70 x 70 mL = 4,900 blood volumes per minute

To know the insufficiency of cardiac impulse, And the cardiac cycle (major and minor) - the cardiac cycle is one major cycle Systemic But the blood is divided into (To nourish: the carotid brain cycle, Pulmonary cycle, clinic ileum cycle, Liver Portal Circulation (portal), The blood circulation cycle in the body in the case of sports activity where there are sensors to increase blood, or in the case of sexual intercourse blood collects in the pelvis for an erection Therefore, in normal cases we do not feel the work of these devices inside the body, except in abnormal cases that appear and the patient feels gases and stomach pain .. The pulse is fast or slow, depending on the state of sleep. Jogging, resting, being a difference in the pulse that links there are causes Extracardial and the reasons for Endocardial are important in the application of the arrhythmia rate formula :

(AR) = [ECG algorithm (Pulse-Oxygen) + Chronic Disease + Recurrence status + Factor Risk + Completion + Treatment].

In addition to laboratory analysis, radiological, Echo-study, treadmill test, Halter, Stress test, ECG, diagnostic and therapeutic cardiac catheters, catheters Ablation, pacemaker, ECG, Effort test, physical Excemtation, DC-shock (electric), Atherosclerosis (Retiring automaticity TO (SA--NOD), Carotid Massage, Valsalva manoeuvre(vagal), Bp, Pharmacology Test (Using atropine 0.5 diluted with water intravenously to see the extent of the increase in the pulse in the case of the block and the decrease in the heart rate), **1) strategy-** The early system of prevention and treatment, the dimensions of risk factors and the true cause of arrhythmia, **2) strategy-** The patient is included in the periodic program of Intensive Cardiac program (I.C.P) making a check-up every 3 months, **3)Strategy-** The most effective treatment chosen is the most effective depending on the calculation of the dose: Initial dose, therapeutic dose, maintenance dose, lethal dose, And the safe dose that does not cause side effects to the patient, we used medicines : For stomach, colon (GIT) and constipation: PPI Omprazole 20 mg. Colon Spasmen tablets, for Anti-constipation Laxdale tablets, lactulose syrap, Enema, Anti-fungal, anti-inflammatory of the urinary tract, anti-inflammatory pulmonary, and antihypertensive and heart medications group: ACE, Angiotensin II receptor(ARB_S), Ca_2^+ Channel Blockers, diuretic, sotalol tablet, (Amidaron 200mg Pills limited time 2 days off holiday in weak), Antioxidants, denxit (Antidepressant), Isosorbide dinitrate, Isosorbide mononatrat 20, 10, 5mg, propafenone, flecanide, aspirin, Plavix, Warfarin, Heparin, thrombolytic Acetylates in Resuscitation, Anti-libedemia statin, vibrate, Mg supplement tablet, Omega 3 tab, Vit B_{12}, Diabetes medications (metformin tab 500mg, diaonl tab 5mg, Ameral tab 1-6 mg, insulin soluble, mixture, lente), Digoxin 0.25, hydrocortisone, anti-allergic drug, fluid

I.V, Glucagon Vial for hypoglycemia, Feroplex (Iron), And by using studied scientific strategies, treatment and correct orientation of the lifestyle, calculation and application of formula that focus on the arrhythmia, And its origin, the true cause, and the early prevention prematurely, which helped a lot to curb the arrhythmia disease in the reduction of heart disorders and through careful follow-up of patients, **Especially young people** of both sexes. And knowing the real reason for the inheritance and their arrival to a state of stability : 65% arising from a nervous source, cramps and constipation, especially irritable bowel, gas, and gastrointestinal disorders, hypo –hyper thyrodism, Thyroid gland 6.2%, discomfort, adequate sleep, mental state, hope, stress, anxiety, high temperature, and food regulation 36.3%, anemia 4.1%, polycythemia 3.2%, Incorrect use of drugs 6.1%, I.H.D. 0.8%, Myocarditis 0.001%, pericarditis 0.002, Cardiomyopathy 0.002, Myocarditis 0.002 >> Diseases of the heart valves 6.2%, rheumatic heart disease 2.1%, pericarditis 002%, Congenital heart disease 0.02%, heart failure 0.0001, pulmonary embolism 0.001, Hypertension 11%, Tachyarrthymia 3%, bradyarrthymia 4.1%, Atrial fibrillation(AF) 0.7%, ventricle fibrillation 0.0001%, Exstrasystoles (ectopic) 3.4%, prolong Q-T 0.6% . heart block 2.3%, .wolf Parkinson syndrome 0.02%, DC shock VT 1.2% Atrial flatter 0.0.01% . pacemaker (ICD Implantable cardiac defibrillator) 0.2%, Catheter ablation therapy 0.6%, As for the majority of **women after 50 years** of age, they are more prone to heart disease and pressure: - Anemia 7.2%, pressure BP 13.3%, diabetes 12.4%, ischemia heart disease 9.1%, stomach and intestinal disorders 7.1%, chronic diseases 12%, Tachyarrthymia 4%, bradyarrthymia 2.5.%, prolong Q-T 1.2%, Atrial fibrillation(AF) 4.7%, wolf Parkinson syndrome 0.01%, ventricle fibrillation 0.03%, Exstrasystoles (ectopic) 9.4%, STEMI 3.1%, NSTEMI 4%, ventricle tachycardia 5.3%, Atrial tachycardia 4.3%, Atrial breadycardia 2.1%, Aheart block 3.3%, Stroke 0.3%, Cardiac catheterization PCI 6.2%, DC cardioversion 0.8%, Catheter oblation therapy 5.1%, Arterial flatter 1.7%, Cardiomyopathy 0.4%, Diseases of the heart valves 6.2%, rheumatic heart disease0.7%, pericarditis s0.4%, Congenital heart disease 0.3%, heart failure 1.7%, pulmonary embolism 0.02%, - As for **men after 50 years**, they are more likely to suffer from stress and more care for them as a result of the health and economic conditions that have negatively affected them. More attention is needed, the most prominent of which are: anemia 1.6%, polycythemia 0.4%, ischemia 12.2%, pressure 12.1%, diabetes 15.2%, pacemaker (ICD) 1%, Catheter oblation 1.2%, DC cardioversion, Arterial fibrillation (AF) 3.1%, Ventricle tachycardia 5, 4%, Arterial tachycardia 4.1%, Arterial breadycardia2%, Ventricle Fibrillation 0.6%, Extrasystoles 6.2%, prolong Q-T 0.8% Heart Block 2.1% heart block 2.1%, L.V desfecation 9.2%, tachycardia 6.2%, bradycardia 0.6%, wolf Parkinson syndrome 0.001%, Arial flatter 2.6%, STEMI 4.2%, NSTEMI 6.1%, Cardiac catheterization PCI: 3%, catheter oblation 2.1%, Myocarditis 0.01%, Cardiomyopathy1.3%, Diseases of the heart valves3.2%, rheumatic heart disease1.2%, pericarditis0.2%, Congenital heart disease 0.3%, heart failure 7.1%, pulmonary embolism 0.0.1%, Hypertension 12.2%, Therefore, the work was as a key and an indicator of the dimensions of the risk factors and the real cause of the Arrhythmia, the calculation of the recombinant rates and the programs. (ICP) Intensive Care Program with the initial stability, And the early treatment plan for heart disease and the accompanying chronic diseases. As for patients who complain of heart valve diseases(transplantation), open-heart operations, congenital anomalies that need surgery, they are referred to heart surgery to stabilize their health condition.

Table (2): Clinical coronary disease and pathology

No	Clinical problem	Pathology
1.	Stable angina	Ischemia due to fixed athermanous stenosis of one or more coronary arteries
2.	Unstable angina	Ischemia caused by dynamic obstruction of a coronary artery due to plaque rupture with superimposed thrombosis and spasm .
3.	Myocardial infarction (MI)	Myocardial necrosis caused by acute occlusion of a coronary artery due to plaque rupture and thrombosis.
4.	Heart failure	Myocardial dysfunction due to infarction or ischaemia
5.	Arrhythmia	Altered conduction due to ischaemia or infarction
6.	Sudden death	Ventricular arrhythmia, a systole or massive myocardial infarction

Discussion

The medical thinking stemmed from the analysis of laboratory and radiological data, method of examination, diagnosis, analysis of patients' cases, respiratory rate per minute, pulse and heart rate quality, blood analysis and electrocardiogram (ECG), Radiology, and all the necessary medical analyzes and supplies linked to the scientific references, the World Health Organization, international societies, and the approved work protocols were ready, present and organized in stages. We have adopted the creation of real equations that combine Information to help and develop a new technique surrounding fatal heart disorders, coronary artery disease, heart structure and curative solutions from their origin and to know the main cause of them. We worked with three early system strategies with the dimensions of risk factors and searched for real external causes such as chest infections, gastrointestinal disorders, hepatic, strokes, and inside the heart. Abnormalities or after myocardial infarction and myocardial emergence in dealing with them, their rate of occurrence, complete disease history and program Cardiac condenser and includes all supplies and diagnostic tests that help and stop the occurrence of germination and avoid it, And the patient's submission to the treatment plan and his response to it, and calculating the dose Initial dose, therapeutic dose, maintenance dose, The recurrence of the arrhythmia cases was of great importance to learn and review all measures to protect the patient and according to the cases that require transplantation pacemaker Or work catheter oblation Or open heart operations (CABH) By giving the appropriate medical decision . I am sure to take into account the patient's psychological and social condition and their family obligations. Among the most prominent arrhythmia at risk are: VF, AF, heart block, and Wolff-Parkinson-White syndrome, Extrasystoles to the many irregular and established origins arrhythmia AF, VF, Explained to us, it is determined on the ECG or ECG in the oblation catheter process that works by scanning the heart and determining the focus that causes the problem and ironing it and ending it with a thermal laser with a Keynes device to curb arrhythmia As for the majority of young people, it originated outside the heart, causes psychological states, and anomalies arrhythmia It was a clear and accurate indication for us to avoid it. As for women, they are the most different disorders of nervous origin, gastrointestinal disorders, colon and gynecological diseases, atherosclerosis, pressure, and coronary artery diseases. And chronic diseases associated with an increase or decrease in the thyroid gland. As for men, they are more prone to stress, work, nervous and muscle spasms, coronary artery diseases, and chronic diseases that negatively affect their lives. Inform the impact on emergence arrhythmia Therefore, the evaluation was useful in developing scientific and applied capabilities .

Results

We rely on results, data, and practical extrapolation of patients and disease cases that were dealt with and collecting the most prominent information that was a useful and beneficial indicator for patients :

Young people And knowing the real reason for the inheritance and their arrival to a state of stability : 65% arising from a nervous source, cramps and constipation, especially irritable bowel, gas, and gastrointestinal disorders, hypo –hyper thyrodism, Thyroid gland 6.2%, discomfort, adequate sleep, mental state, hope, stress, anxiety, high temperature, and food regulation 36.3%, anemia 4.1%, polycythemia 3.2%, Incorrect use of drugs 6.1%, I.H.D. 0.8%, Myocarditis 0.001%, pericarditis 0.002, Cardiomyopathy 0.002, Myocarditis 0.002 >> Diseases of the heart valves 6.2%, rheumatic heart disease 2.1%,pericarditis 002%, Congenital heart disease 0.02%, heart failure 0.0001, pulmonary embolism 0.001, Hypertension 11%, Tachyarrthymia 5%, bradyarrthymia 2.1%, Atrial fibrillation(AF) 0.7%, ventricle fibrillation 0.0001%, Exstrasystoles (ectopic) 3.4%,prolong Q-T 0.6% . heart block 2.3%, .wolf Parkinson syndrome 0.02%, DC shock VT 1.2% Atrial flatter 0..01% . pacemaker (ICD Implantable **.**

Women after 50 years of age: They are more prone to heart disease and pressure: Anemia 7.2%, pressure BP 13.3%, diabetes 12.4%, ischemia heart disease 9.1%, stomach and intestinal disorders 7.1%, chronic diseases 12%, Tachyarrthymia 4%, bradyarrthymia 2.5.%, prolong Q-T 1.2%, Atrial fibrillation(AF) 4.7%, venticwolf Parkinson syndrome 0.01%,ventricle fibrillation 0.03%, Exstrasystoles (ectopic) 9.4%, STEMI 3.1%,NSTEMI 4%,ventricle tachycardia 5.3%, Atrial tachycardia 4.3%, Atrial breadycardia 2.1%, Aheart block 3.3%, Stroke 0.3%, Cardiac catheterization PCI 6.2%, DC cardioversion 0.8%,Catheter oblation therapy 5.1%, Arterial flatter 1.7%, Cardiomyopathy 0.4%, Diseases of the heart valves 6.2%, rheumatic heart disease 0.7%, pericarditis s0.4%, Congenital heart disease 0.3%, heart failure 1.7%, pulmonary embolism 0.02%.

Men after 50 years: They are more likely to suffer from stress and more care for them as a result of the health and economic conditions that have negatively affected them. More attention is needed, the most prominent of which are: anemia 1.6%, polycythemia 0.4%, ischemia 12.2%, pressure 12.1%, diabetes 15.2%, pacemaker (ICD) 1%, Catheter oblation 1.2%, DC cardioversion, Arterial fibrillation (AF) 3.1%,Ventricle tachycardia 5,4%, Arterial tachycardia 4.1%, Arterial breadycardia 2%, Ventricle Fibrillation 0.6%, Extrasystoles 6.2%, prolong Q-T 0.8% Heart Block 2.1% heart block 2.1%, L.V desfecation 9.2%, tachycardia 6.2%, bradycardia 0.6%, wolf Parkinson syndrome 0.001%, Arial flatter 2.6%, STEMI 4.2%, NSTEMI 6.1%, Cardiac catheterization PCI: 3%, catheter oblation 2.1%, Myocarditis 0.01%, Cardiomyopathy 1.3%, Diseases of the heart valves 3.2%, rheumatic heart disease 1.2%, pericarditis 0.2%, Congenital heart disease 0.3%, heart failure 7.1%, pulmonary embolism 0.0.1%, Hypertension 12.2%, Therefore, the work was as a key and an indicator of the dimensions of the risk factors and the real cause of the Arrhythmia, the calculation of the recombinant rates and the programs ..(ICP) Intensive Care Program with the initial stability, And the early treatment plan for heart disease and the accompanying chronic diseases .. As for patients who complain of heart valve diseases(transplantation), open-heart operations, congenital anomalies that need surgery, they are referred to heart surgery to stabilize their health condition .

Table (3): Results of the most prominent disease cases arrhythmia (cardiac disorders) according to data and practical extrapolation (ECG)

No.	Arrhythmia	Youth - % (20-50) year	Women after 50 years-%	Men after 50 years- %
1.	Sinus Arrhythmia	3%	4%	6.2%
2.	Sinus Bradycardia	2.1%	2.5%	1.7%
3.	Sinus Tachycardia	5 %	3%	6.2%
4.	Atrial tachyarrhythmia's	2.3%	4.3%	4.1%
5.	Atrial breadycardia	2.1%	2.1%	2%
6.	Atrial flutter	0.01%	1.7%	2.6%
7.	Atrial fibrillation	0.7%	4.7%	3.1%
8.	Ventricle fibrillation	0.001%	0.03%	0.6%
9.	Ventricle tachycardia	4.1%	5.3%	5.4%
10.	Excrasystol (ectopic)	3.4%	9.4%	6.2%
11.	Long Q -T Syndrome	0.6%	1.2%	0.8%
12.	Heart block	2.3%	3.3%	2.1%
13.	Wolff-Parkinson-White Syndrome	0.01%	0.01%	0.001%
14.	STEMI	0.001%	3.1%	4.2%
15.	NSTEMI	0.003%	4%	6.1%

Table (4): Summary of treatment Anti-arrhythmic drug According to classification (Sigh Vaughan William) (Oxford university)

Class/Ion Affected	Agents	Physiologic Effect	Result on Electrophysiologic Parameters	Clinical Utility
Class I (Na^+ channel blockers)				
IA (intermediate)	Disopyramide Quinidine Procainamide	↓ Conduction velocity ↑ Refractory period	↑ QRS complex and ↑ QT interval	Atrial and ventricular arrhythmias
IB (fast)	Lidocaine Mexiletine	↓ Conduction velocity ↓ Refractory period	↓ QT interval	Ventricular arrhythmias
IC (slow)	Flecainide Propafenone	↓↓↓ Conduction velocity Ø Refractory period	↑ QRS complex	Supraventricular arrhythmias and ventricular arrhythmias
Class II (β-Blockers)	Metoprolol Esmolol Atenolol	↓ Conduction velocity ↑ Refractory period	↓ HR and ↑ PR interval	Atrial and ventricular arrhythmias
Class III (K^+ channel blockers)	Amiodarone Dronedarone Sotalol Dofetilide Ibutilide	Ø Conduction velocity ↑↑↑ Refractory period	↑ QT interval	Atrial and ventricular arrhythmias
Class IV (Ca^{2+} channel blockers)	Diltiazem verapamil	↓ Conduction velocity ↑ Refractory period	↓ HR and ↑ PR interval	Atrial and ventricular arrhythmias

Conclusion

The new scientific effort contributes to the development of work by treating patients safely, especially due to what our countries suffer according to the available capabilities to reduce heart disease and the essence of Arrhythmia Which was our main topic, which causes angina pectoris and when it leaves side effects on human health, work is limited to patients, causes outside and inside the heart.

Effectiveness of an Educational Program on Nurses' Knowledge about Communicable Diseases Control in Al-Nassiriyah City Hospitals

Talal Mohammed Yousef[1], Wissam Jabbar Qassim[2], Zahid Jassim Mohammed[3]

[1]M.Sc. Student, University of Baghdad, College of Nursing, Community Health Nursing Department, Iraq, [2]Assist. Professor PhD, University of Baghdad, College of Nursing, Community Health Nursing Department, Iraq, [3]Assist. Professor Basic science Department, College of Nursing, University of Baghdad, Baghdad City, Iraq

Abstract

Communicable diseases are an illness that is transmitted from a person, animal, or inanimate source to another person either directly, with the assistance of a vector or by other means. Communicable diseases are a major cause of mortality and morbidity in emergencies, and particularly in complex emergencies, where collapsing health services and disease control programs. They are the basic level of infectious pathogens control precautions which are to be used, as a minimum, in the care of all patients. A quasi-experimental design (descriptive study) used to guide this study; it was applied by use of pretest-posttest approach for two groups of samples (study and control) Non- probability (purposive) sample of (80) nurses who are working in Al-Nasiriyah city hospitals.

The findings of the current study revealed that there are highly statistically significant differences in posttest. The study concludes that there is poor and low level of knowledge assessment among the participants toward communicable diseases control at the pre-test in the both group. The results show after the implementation of educational program high level of nurses' knowledge for (post-test I and post-test II) for the study group regarding communicable diseases control. The study concludes there were no significant association between nurses' knowledge and their socio demographic characteristics includes: age; gender; level of education and years of experience. The study recommends of the providing an educational and training program periodically for nurses in order to enhancement the level of their knowledge regarding communicable diseases control.

Keywords: *Effectiveness of an educational program, nurses› knowledge,communicable diseases control.*

Introduction

Communicable diseases are an illness that is transmitted from a person; animal or inanimate source to another person either directly, with the assistance of a vector or by other means. Communicable diseases cover a wider range than the person to person transmission of communicable diseases[1].

In the fall of 2002, the WHO program on communicable diseases in complex emergencies coordinated the compilation of the communicable disease profile for Iraq. This profile highlighted the most prevalent risks for public health and included a communicable disease toolkit, including rapid health assessment forms, morbidity and mortality surveillance forms, case definition for priority diseases, and guidelines for case-management and outbreak control [2].

Communicable diseases are a major cause of mortality and morbidity in emergencies, and particularly in complex emergencies, where collapsing health services and disease control programs, poor access to health care, malnutrition, interrupted supplies and logistics, and poor coordination among the various agencies providing health care often coexist. The main causes of morbidity and mortality in emergencies conditions are diarrheal diseases, acute respiratory infections, and measles in areas where it is endemic, malaria. Other communicable diseases, such as epidemic meningococcal disease, Tuberculosis, relapsing fever, and Typhus, have also

caused large epidemics among emergency-affected populations[3].

World Health Organization (2012), an annual report which stated that the importance of communicable diseases control has increased in recent years due to increased travel, trade, migration and emergence of new infections. In addition to the chronic challenges of weak health systems, inadequate commitment and financing for communicable diseases control have resulted in delay to achievement of regional targets. Several countries are facing political instability, social unrest, ongoing conflict and insecurity, all of which have an impact on control of communicable diseases. In this section, we address four thematic areas: poliomyelitis eradication; HIV, TB, hepatitis B,C, malaria and tropical diseases; immunization and vaccines [4].

Hospital acquired infection (HAIs) can be defined as an infection acquired in hospital by a patient who was admitted for a reason other than that infection. An infection are occurring in a patient, in a hospital or other health care facility in whom the infection was not present or incubating at the time of admission. This includes infections acquired in the hospital but appearing after discharge, and also occupational infections among staff of the facility [5].

Nurses are health care professionals whose duty it is to protect patients from acquiring infections while hospitalised or while in a health care set up. By maintaining an infection free environment, the patient's recovery will be promoted and high-quality nursing care will be delivered. Nurses spend most of their time with patients. Therefore, they should have a good level of understanding of the knowledge on prevention and control measures about communicable diseases in health care setups [6].

For example the tuberculosis (TB) is a public health priority in Iraq. The country is among the seven of the countries of the region with a high burden of TB, and accounts for 3% of the total number of cases. There are an estimated 20 000 TB patients in Iraq. Estimated deaths due to TB are more than 4000 annually. Iraq reported that there are about 8,664 new cases of tuberculosis in 2012 and a prevalence of 73 cases per 100,000 populations. Within Iraq, 180 new cases of multidrug-resistant tuberculosis were confirmed [7].

Method of the Study

A quasi-experimental design (descriptive study) used to guide this study. It was applied by use of pre-posttest approach for two groups of samples (case and control) to determine the effectiveness of an educational program on nurses' knowledge about communicable diseases control during period from 15th October 2019 to 20th August 2020.

Non- probability (purposive) sample of (80) nurses who are work -ing in isolation department of Al-Nasiriyah city hospitals (Al-Hussein Teaching Hospital, Bent Al-Huda Teaching Hospital and Al-Habbobi Teaching Hospital). The sample consists (80) nurses divided into two groups: (40) nurses as study group, which exposed to the health educational program and (40) nurses as control group who not exposed to the health educational program.

Study Instrument: The tool for the study, including four parts, first concerned with the nurse's demographic characteristics like nurses' age, gender, level of education, and marital status. The second part includes a series of MCQ questions covering nurses' knowledge about communicable diseases. The test consists of a list of (20) questions and consists of choices**.**Third is concerned with data related to the nurses' knowledge toward method of communicable diseases control, which are consist of (15) questions. The fourth part is concerned with data related to the nurses' knowledge toward standard precautions which are consist of (20) questions.

The content validity of the program and the study instruments are determined by the panel of (13) experts, which have more than (7) years' experience in their field to investigate the content of the educational program and the questionnaire about communicable disease control.

Rating and Scoring: The level of knowledge was scored by rating (2) for the correct answer and (1) for the incorrect one, therefore, knowledge rating explained by the following intervals L=Low level (1-1.33), M=Moderate level (1.34-1.67), H=High level (1.68-2). Data of the study were ordered according to three levels of scale (High, Moderate, and Low) early stated which were scored as (2 and 1) for each level respectively. It is classified as scores of response according to the following:

L=Low level (1-1.33)

M=Moderate level (1.34-1.67)

H=High level (1.68-2)

The Statistical Data Analysis: Data are analyzed through using the program of Statistical Package of Social Sciences (SPSS, Version 21). The following statistical data analysis approaches are used in order to analyze and assess the results of the study.

Results and Discussion

Socio -demographic characteristics of the present study: The table (1) represents the socio -demographic characteristics of the present study (study and control group). It shows the majority of the study and control sample at the middle age ranged (25 - 29) years. For study group are accounted for (24) nurses with represented of percentage (45%), while for control group represent of percentage (60%).

The study findings agree with study in Nigeria that indicated about knowledge and application of infectious diseases control measures among primary care workers in Nigeria. It revealed that most participants (34.2%) of health care workers were age group (25-34)[8].

This is due to the large number of recent employees in the field of health, as the Ministry of Health is working to employ thousands of nurses' graduates annually from specialized institutes and colleges in the health field, so most ages are from this age group.

In regarding for gender, the table shows that the majority of participants were female for both groups (control and study). Which were represented of percentage (57.5%) of all.

The study findings agree with study done in in Nigeria indicated that about knowledge and application of infectious diseases control measures. It revealed that most study sample were female which represented (76.2%).[9].

Concerning the level of education, the present study shows that (19) of participants, nurses in study group were graduated from nursing institute and represented (47%). While for control group, also the most were graduated from nursing institute about (24) nurses with percentage (60%).

The findings supported study in South Africa of for Nurses' knowledge of tuberculosis, HIV, and integrated HIV/TB, which revealed that (54%) of participants nurses had diploma qualification [10].

Regarding to the marital status, results of study show that the majority of control and study sample (75%) were married. This results agree with study by

The study findings are similar with study of Yousef in 2019 to implementing the educational program regarding nurses' knowledge about infection control measures and results revealed that majority (68.75%) were married[11].

Related to the training session, the study findings show that the majority of nurses in study group were (85%), while for control were (77.5) have not participated in a formal educational program about communicable diseases control. Lack of access and interest in the training courses leads to poor skills development of nursing staff regarding the communicable diseases control.

The study findings agree with study of Al-Ghamdi in (2011) that show (57.8%) of health care workers did not participanted in training course about communicable diseases control. These findings reported that the poor nurses' knowledge related to lack of interest and motivation in participating in training course about communicable diseases control [12].

Concerning the years of experience, the study findings reveals that majority of participants for both group (control and study) have (6-10) years in their experience with percentage (45%) for control group and (37.5%) for study group.

The present results agree with study of Hamid in (2010) who conduct a study to assess Knowledge of infectious diseases and the practice of universal precautions amongst health-care workers in a tertiary hospital in Malaysia. They found the (79%) of participants have experience in range of (5-9) years [13].

Table(2) shows that distribution of knowledge scores general information on (communicable diseases, method of control, and standard precautions) and indicated was that high level of knowledge related to study group.

Table (3) shows all three posttest nurses' knowledge scores general information on (communicable diseases,

method of control, and standard precautions) to be significantly higher between the study group and control group.

The study findings supported by study done in Egypt were noted that the effect of educational program for knowledge of nurses for study group at a posttest [14].

Anther study support the present study results, which reported the effect of educational program on nurses' compliance with Universal precautions of infection control and noted high significant differences between study and control group [15].

Before the implementation of the educational program, a pre-test was carried out on study group and results show the level of nurses' knowledge regarding three domains of communicable diseases control was poor.

These results agree with study done in Saudi Arabia. Saudi was reported that nurses had poor knowledge about communicable diseases control [11].

Also, the result is consistent with that findings obtained by Phetlhu in (2018) which revealed that the most nurses have poor knowledge concerning communicable diseases [9]

Association between socio-demographic characteristics and nurses' knowledge: Results of tables (4) showed that there is no statistical significant association between nurses' knowledge and their gender at (pre-test, post-test I and posttest II tests) of educational program follow up (p value > 0.05), and also there are no differences between mean of knowledge.

The study findings agree with study soudiarab was stated that no significant association between genders of nurses concerning communicable diseases contro[11]

Table (4) shows that there is no statistical significant association between nurses' age and their knowledge regarding communicable diseases control.

The findings supported by study of Phetlhu in (2018) who state that there is no is no statistical significant association between nurses' age and their knowledge at ($p \leq 0.05$ value) [9].

Additionally, to another study conducted in egipt which noted that there is no significant relationship between nurses' age and their knowledge toward standard precautions and infection control [15].

Table (4) regarding the level of education, it shows there is no signification association between the educational level and nurses' knowledge concerning communicable diseases control.

Results agree with Batranin(2018) conduct a study on nurses' knowledge about standard precautions and reveals that there is no singnificat association between educational level and knowledge [16]

Table (4) according to results of this table, there is no significant between experience for nurses' work and their knowledge concerning communicable diseases control (p value > 0.05).

Results agree with study by Hamid in (2010) about Knowledge of infectious diseases and the practice of universal precautions amongst health-care workers. It noted that no relation between years of experience of health-care workers and their knowledge[12].

Additionally, study in Ninavah Covernorate was showed that there ere no significant statistical differences in post – test scores between nurses' knowledge with regard to their years of employment[17].

Table (1): Distribution of The Study Sample by Socio- Demographic for Study and Control Group

Evaluation Follicular Fluid Cytokines in Patients with Risk Factor for Development of Ovarian Hyper Stimulation Syndrome

Alaa K. Hameed[1], Alaa S. AL-Atabbi[2], Muna K. Mahmood[3]

[1]Masters Degree Student, College of Medicine, University of Kerbala, Kerbala, Iraq, [2]Ass. Prof. College of Medicine, University of Kerbala, Kerbala, Iraq, [3]Ass. Prof. College of Medicine, University of Kerbala, Kerbala, Iraq

Abstract

Aim of Study: Study the level of IL17 and IL23 in the follicular fluid and their relation with hyper stimulation syndrome.

Materials/Method: Eighty five who include (85 subject divided into 2 groups, control group whom included infertile female with male factor infertility (55) and case group whom infertility due to poly cystic ovarian syndrome (30) attended IVF centre.

Samples collected were follicular fluid, the follicular fluid has been collected in Eppendorf tube then stored at -20c to be used for ELISA test to determine concentration of IL 23 and IL 17 in follicular fluid. The results were analyzed using the IBM SPSS analytic software.

Results: the mean of interleukin (IL17) 96.11, Standard deviation 78.46 in the patients group. While the mean of interleukin (IL 17) for control 6.15, Standard deviation 14.33. There was a significant difference between polycystic and male factor infertility. P value < 0.005 both of them groups Poly cystic and male factor.

Conclusions: High concentration of follicular fluid IL -17 is positively associated with e disease of poly cystic ovary (POCS).

Keywords: *PCOS, IL17, IL23, fertility.*

Introduction

IVF stands for in vitro fertilization. It's one of the more widely known types of assisted reproductive technology (ART). IVF works by using a combination of medicines and surgical procedures to help sperm fertilize an egg. Where fertilization takes place outside the body. It's suitable for people with a wide range of fertility issues and is one of the most commonly used and successful treatments available for many people[(1)]. There are many types of fertility treatments available, ranging from simple interventions such as medication to help a woman ovulate through to more complicated procedures like IVF[(2)].

Ovarian hyperstimulation syndrome (OHSS) is considered the most serious complication of ovulation induction. It can vary from being a mild illness to a severe, life-threatening disease requiring hospitalization. OHSS can occur as soon as a few days after receiving HCG ('early OHSS') or later ('late OHSS'). Multiple pregnancy has been shown to be associated with a higher risk of late OHSS [(3)].

The incidence of severe OHSS has been reported to vary from 0.7 to 1.7% per initiated cycle[(4-7)]. Some

case reports[8, 9], studies[5, 10], and reviews[11] describe some serious aspects of OHSS, such as thromboembolic events, pulmonary manifestations, and death, but the magnitude of the risk is unclear.

While there is robust evidence supporting the efficacy and safety of ART, it is important to be aware of the risks, the most serious of which is ovarian hyperstimulation syndrome (OHSS). OHSS is a rare, iatrogenic complication of controlled ovarian stimulation (COS). Severe OHSS occurs in approximately 1.4% of all cycles[12].

There are a number of well-established primary risk factors for the development of OHSS, including young age, polycystic ovary syndrome (PCOS) – characterized by ultrasound and the ratio of luteinizing hormone (LH) to follicle stimulating hormone (FSH) – and a history of an elevated response to gonadotropins, i.e. prior hyper-response/OHSS[13, 14].

The polycystic ovary syndrome (PCOS) is the most common endocrine disorder of women in reproductive age which influences outcome and potential risks involved with controlled ovarian stimulation for artificial reproductive techniques (ART)[15]. It causes chronic oligo- or anovulation and often leads to infertility.

PCOS is mentioned as a common endocrinopathy in women who are at reproductive age and it is associated with metabolic disorder and reproductive dysfunction[16,17].

Ovarian dysfunction continues to be the main feature which makes this syndrome the major cause of an ovulatory associated with infertility[18]. Most say 5%-10% of reproductive-age women are affected[19, 20] but some say 6.6%-8%[21] and some others say PCOS is a disorder affecting up to 6%-10% of women in reproductive age[22].

This syndrome can be defined by specific clinical and bio-chemical criteria, and also using ultrasonography[23].

Environmental status and factors, such as obesity, appear to exacerbate the underlying genetic predisposition. PCOS is characterized by increased levels of circulating androgen, polycystic ovarian morphology (PCOM), arrested follicle development, and an ovulatory infertility[24].

Controlled ovarian hyperstimulation (COS) with gonadotropins for artificial reproductive techniques (ART) leads to a higher risk of ovarian hyperstimulation syndrome (OHSS) for patients affected by PCOS, because of a higher sensibility and exaggerated response to gonadotropins[26].

The Th17/IL-23 immune axis plays an important role in immuno-pathogenesis of some reproductive abnormalities such as polycystic ovary syndrome (PCOS) and endometriosis[27]. IL-23, a member of the IL-12 cytokine family, is a heterodimeric cytokine which is composed of the IL-12 p40 subunit and a novel p19 subunit. IL-23 is mainly secreted by activated macrophages and dendritic cells[28].

The significant higher levels of IL-6 and IL-10 and lower concentrations of IL-23 in FF from patients with PCOS indicated an important immunological microenvironment defect in the ovarian follicles[29]. The high level of IL-23 in the FF of women with endometriosis illustrated inappropriate oocyte quality in these subjects[30].

IL-23 amplifies and stabilizes the proliferation of IL-17 secreting CD4þ memory T cells which produce IL-17, a pro-inflammatory cytokine that stimulates the production of other pro-inflammatory cytokines and chemokines such as IL-1, IL-6, tumour necrosis factor-a and nitric oxide responsible for inflammation[31].

Also, the significantly higher IL-17 in the FF of women with endometriosis and PCOS is associated with immunological changes which may finally lead to infertility[32].

Some past examination exhibited that IL-10 was raised yet IL-23 was evoked in PCOS ladies which reflex sustain the neighbourhood enactment of Th17/ Th1 cells by discharging a lot of IL-22, and IFN-γ-driven inflammation[33].

This study was aimed to investigate the concentration of level interleukin 17 and interleukin 23 and development of PCOS.

Materials and Method

A case control study was conducted in AL – Sader teaching medical city in Najef, AL Kadhimiya Teaching hospital, Umm AL Banin fertility centre and Nahrain Universility Higher institute in Baghdad to diagnose infertility and assist in childbearing randomly selected included a 85 patients, Who attended to consultant clinic for in Vitro Fertilization intracytoplasmic sperm

injection in the period between November 2019 to March 2020 under the supervision of fertility and in vitro fertilization specialists were included in this study.

Eighty five who include (85 subject divided into 2 groups, control group whom included infertile female with male factor infertility (55) and case group whom infertility due to poly cystic ovarian syndrome (30) attended IVF centre.

Samples collected were follicular fluid, Oocyte Pick up was done by a gynaecologist. Follicular fluid sample were collected by Needle size 16 Cage from ovary from 90 patients and their healthy controls and put in tube then, allowed to separate by centrifugation 3000 rpm for 5 minute. The follicular fluid has been collected in Eppendorf tube then stored at -20c to be used for ELISA test to determine concentration of IL 23 and IL 17 in follicular fluid.

Results

Table (1) shows that total of 85 groups: 30 patients groups which compared with control groups male factor (N=55). For both studied groups, age ranging from (25-45) polycystic and from male factor (32-42). The mean ages (mean-+SD) were 28.97±4.88 for poly cystic, 29.41±5.59 for male factor.

Body mass index in poly cystic ovary group (mean ±SD) were 26.58±2.52, minimum 22.66, maximum34.05. While control groups male factor (mean± SD) were 26.32±3.46, minimum 10,82 maximum 32.83

Infertility duration for polycystic ovary groups (mean± SD) were 8.20±2.28, minimum 6, maximum 11. While for control male factor groups (mean± SD) were 7.79±2.99, minimum 3, and maximum 13.

Right ovary follicle for poly cystic ovary groups (mean± SD) were 6.6±3.7, minimum 1,maximum 15.While for control male factor groups (mean± SD) were 6.1±3.6, minimum 1,maximum 17.

Left ovary follicle for polycystic ovary groups (mean± SD) were 6.10±3.39, minimum 1, and maximum 13. While for control male factor groups (mean± SD) were 5.47± 2.97, minimum 0.00, and maximum 13. The zero score with mean 00±0. P value is (>0.05) Non signification.

Table (1): Patient's Demographic characteristics.

Discussion

Patients were asked about their medical history which included any past taken un-prescribed medications, psychological traumas, family history and any other causes of PCOS. There was no significant correlation found between the patients of PCOS and controls in regards to their medical history. Data collected from literature disagrees with our results in this regard, as a study by[41]found that there was a difference in prevalence of PCOS between urban and rural areas as a result of different effects of environmental or risk factors on the occurrence of the disease including the psychological trauma and physical activity.Another study by[42]had found an influence of the family history, physical activity and stress on the occurrence of PCOS patients in comparison to controls.

A study found that the uptake of hormonal un-prescribed medication had an effect on vitamin D deficiency witch in turns is a risk factor for PCOS. Another study found that the hormonal changes are a significant risk factor for PCOS patients[43]. Primary and secondary infertility were both found insignificant when correlated with PCOS patients and controls[44]. Primary infertility was defined as failure to become pregnant after at least one year of unprotected intercourse, while secondary infertility refers to women who have been pregnant at least once but failed to conceive after at least one year of unprotected intercourse[45]. A study by[46] found a significant correlation between primary and secondary infertility between patients and control groups. The same conclusions were made by[45]as a significant correlation was found between primary and secondary PCOS patients and their control group. also no significant relation was found by this study upon comparison of the number of miscarriages in PCOS patients and controls. In this study sample over 90% of both groups had no miscarriages, this could explain the difference between our results and those of other studies. The risk of miscarriage in PCOS patients is increased and amounts to 30–50%, which means that for these women, it is three times as high as for healthy women[47]. The results of prospective, randomized trials suggest that the miscarriage instances in PCOS patients occur only in 15–25% of cases, which is a percentage comparable with the frequency of miscarriage in the general population[48, 49]. Unlike this study,[50, 51]had both found a significant correlation between patients and controls in regards to miscarriages. Polycystic ovarian syndrome (PCOS) induces anovulation in women of reproductive age, and is one of the pathological factors involved in the failure of in vitro fertilization (IVF). Indeed, PCOS women are characterized by poor quality oocytes[52].

A valuable indicator of OHSS risk is estradiol serum level. It is recommended that E2 serum levels be determined during ovarian stimulation.[55]have investigated the estradiol serum level in PCOS patient and the predisposition of PCOS to OHSS and its relation to Triggering ovulation with gonadotropin-releasing hormone agonist in in vitro fertilization patients with PCOS. Several studies on the PCOS models of rats have effectively used estradiol in the induction of PCOS in rats proving the significance of the correlation between estradiol and PCOS[56, 57]. These results contradicts this study findings. A study by[58]have matched the characteristics of women with PCOS with their controls and found that estradiol serum level was found in a higher levels in women with PCOS than their controls. Study by[59]used multiple logistic regression and showed

that the number of oocytes retrieved, peak estradiol level, number of follicles at oocyte collection, and ovarian morphology (patient group) were all significantly correlated with regard to the patient developing severe OHSS on univariate analysis. Also, the number of follicles, oocytes retrieved and peak estradiol levels were all significantly increased in women with PCO and PCOS. There is a significant predictive association between E_2 levels measured on stimulation day 3 and 5 and both ovarian hyper-response and extreme-response in IVF. However, the clinical value of stimulated E_2 levels for the prediction of hyper-response is low because of the modest sensitivity and the high false positive rate. For the prediction of extreme-response the clinical value of stimulated E_2 levels is moderate[60].

On the contrary to our results, the studies done by (Tsikouras et al, 2015 and Ibanez et al, 2017) revealed a significant increase in the hormonal profile LH, LH/FSH, Testesterone and Progesterone compared to the control group. In women undergoing in vitro fertilization (IVF),[61] reported a negative association between FSH and AMH serum levels, concluding that the AMH level is highly predictive of the FSH level and can be used as an independent indicator of ovarian reserve. Recently,[62]also reported that intrafollicular AMH levels negatively correlated with FSH in follicles of normoandrogenic ovulatory women undergoing IVF, concluding that intrafollicular AMH levels reflect follicle sensitivity to FSH. In study by[63], we noted increased serum AMH levels in women with polycystic ovary syndrome (PCOS). Moreover, AMH levels were negatively correlated to body mass index (BMI) and were independently predicted by the levels of luteinizing hormone (LH) and testosterone and by BMI. We concluded that increased LH levels might be an independent link between PCOS-associated disorders of ovulation and increased serum AMH concentrations.

In conditions of increased LH and normal to low FSH levels (such as in PCOS), the AMH serum levels are increased and tend to be associated with serum LH levels; whereas in conditions of increased FSH levels (such as in premature ovarian failure), AMH serum levels are decreased and tend to be associated with serum FSH levels[64]. A neuro endocrine characteristic believed to be of PCOS is steadily rapid LH (GnRH) pulsatility, which favours pituitary synthesis of LH over that of FSH and contributes to the increased LH concentrations and thereby altered LH: FSH ratios typical of PCOS. Insufficient FSH levels contribute to impaired follicular development, while increased LH levels enhance ovarian androgen production[65]. A study found there was a persistent increase in LH level was noted among PCOS group starting from level of 5.04μlU/ml and reaching up to level of 22.06μlU/ml. Accordingly, LH: FSH ratio also showed a steady increase from 1 to 5.5 in these groups. There were no groups identified on the basis of LH: FSH ratios in the control as their LH: FSH ratios were within the same range[66].

Conclusion

High concentration of follicular fluid IL -17 is positively associated with e disease of poly cystic ovary (POCS).

Methicillin-Resistance *Staphylococcus Aureus* (MRSA) in Hospitals: The Unwanted Guest

Nadhim N. Tahir[1], Saad S. Hamim[2]

1M.Sc, Department of Pathological Analysis-College of Science-Thi-Qar University and Work in Ministry of Health-Thi-Qar Health Directorate, [2]Professor, Department of Pathological Analysis-College of Science-Thi-Qar University

Abstract

Background: Methicillin-resistant *Staphylococcus aureus* (MRSA) is one of the most frequent causes of Nosocomial infections around the world.

Aims: This study aimed to detect some diagnostic genes and some virulence factor genes for MRSA isolates.

Method: During the period of from August to December 2019, 46 MRSA were isolated from different clinical samples such as Urinary Tract Infections (UTIs), Wounds infection's, Diabetics foot patients, Burn patients and Otitis media in Al- Hussain Teaching Hospital in Thi-qar province, Iraq. All MRSA isolates were subjected to conventional Polymerase Chain Reaction to detect 16SrRNA and *mec*A genes and some virulence factors genes *hla* and *tst*-1 genes. Six PCR product were selected and subjected to partial DNA sequencing for the 16SrRNA gene to follow up their possible relationship between them and what recorded globally in Genbank.

Results: The results revealed that all isolates 46(100%) have 16SrRNA, *mec*A, and *hla* genes, While only 23 isolated (50%) have *tst*-1 gene. The six PCR product of 16SrRNA was registered in Genbank under official accession numbers of (MT605393.1, MT605385.1, MT605394.1, MT605386.1, MT605387.1, and MT605388.1). The phylogenetic tree that was constructed by MEGA10 software showed that there were different molecular relationships among the local *Staph. aureus* isolates with analogous ones around the world.

Keywords: *MRSA;Gene sequencing, Phylogenetic tree, Diagnostic genes, Virulence factors.*

Introduction

One of the main public health problem worldwide, especially in developing countries Nosocomial infections (NIs) [1]. As these infections can occur through hospital admission, they cause long stay, incapacity, and economic load. Commonly prevalent infections include central line-associated bloodstream infections, catheter-associated urinary tract infections, surgical site infections and ventilator-associated pneumonia. There are several pathogens cause nosocomial infections, these pathogens include bacteria, viruses,fungal and parasites[2]. Methicillin-resistant *Staphylococcus aureus* (MRSA) is one of the most common reasons of hospital- and community-associated infections. The ability of this bacteria to resist to the entire class of β-lactam antibiotics, such as methicillin and penicillin, therefore makes MRSA infections difficult to treat[3]. For instance, when the starter of penicillin to the market for the treatment of hospitalized patients, the resistant strains to the penicillin rapidly appeared[4]. Presently, MRSA strains account for various of Staphylococcal infections and increasing reports of MRSA strains in the worldwide[5].

Material and Method

Samples Collection: A total of 46 MRSA were isolated from patients of both gender of different ages who suffered from symptom-based Urinary Tract Infections (UTIs), Wounds infection's, Diabetics feet patients, Burn patients and Otitis media. A patients took

care and medication at AL-Hussain Teaching Hospital in AL-Nasiriya City, Southern Iraq from August to December 2019.

Isolation and identification of *Staphylococcus aurues:* The collected specimens were inoculated onto blood agar, mannitol salt agar,and MacConkey agar according to standard method. *Staph. aureus* was identified depending on the morphologicalfeatures (colony size, shape, color, hemolysis, translucency, edge, elevation, and texture) on culture media[6]. The biochemical tests were used include Catalase, Coagulase, Oxidase and Novobiocin [7]. The diagnostic of bacteria were confirmed by API system and Vitek2 compact (biomerieux, France).

Molecular Detection of *Staph. aureus:* 1.Genomic DNA was extracted from MRSAisolates by using Genomic DNA Mini Bacteria Kit (Anatolia/Turkey). **2.** All MRSAisolates were subjected to the detection of 16SrRNA,*mec*A, *hla*,and *tst*-1 genes by conventional PCR technique using specific primers pairs for every gene (Table1). The amplification genes were put into the thermo cycler (ABM Canada) and the right PCR cycling program parameters conditions were adjusted according to each primer.

Table 1:Specific primers of *Staph. aureus*.

Gene	Primer sequences (5˚ – 3˚)		Product size (bp)
16SrRNA	F	AGAGTTTGATCCTGGCTCAG	1500
	R	GGTTACCTTGTTACGACTT	
*mec*A	F	TGAGTTGAACCTGGTGAAGTT	855
	R	TGGTATGTGGAAGTTAGATTGG	
tst-1	F	ACCCCTGTTCCCTTATCATC	326
	R	TTTTCAGTATTTGTATCGCC	
hla	F	GAAAACACGTATAGTCAGCTCAGTAAC	951
	R	GTCATTTCTTCTTTTTCCCAATCG	

Sequencing Analysis: The PCR product of six MRSA isolated from different infected sites were subjected to partial sequencing of 16SrRNA gene and blasted in NCBI against standard strains of *Staph. aureus*. The samples sequences which assigned primarily as (N STQ1,NSTQ2,NSTQ3,NSTQ4,NSQ5,and NSTQ6). A phylogenetic tree for genes sequence was constructed by using (MEGA10) software[8].

Results

Detection of 16SrRNA and *mec*A genes: All MRSA isolates (n=46) were diagnosed by conventional PCR technique through the amplification of 16SrRNA and *mec*A genes to confirm that the verified isolates are *Staph. aureus* and MRSA, respectively. The results showed that all isolates were positive for both the targeted genes. the size of products were approximately 1500 bp for 16SrRNA gene and approximately 855 bp for *mec*A gene.

Detection of virulence genes: Two of virulence genes of MRSA were detected through the amplification of *hla* and *tst*-1 genes. The results revealed that all isolates 46(100%) had *hla* gene and only 23 isolated (50%) had *tst*-1 gene a with a product sizes of approximately 951 bp and 326 bp, respectively (Fig.1, 2).

Phylogenetic analysis: The six selected MRSA strain granted the official Genbank accession numbers of MT605393.1, MT605385.1, MT605394.1, MT605386.1, MT605387.1 and MT605388.1. The phylogenetic tree that was constructed by MEGA10 software showed that there were different molecular relationships among the local *Staph. aureus* isolates with analogous ones around the world (Fig. 3).

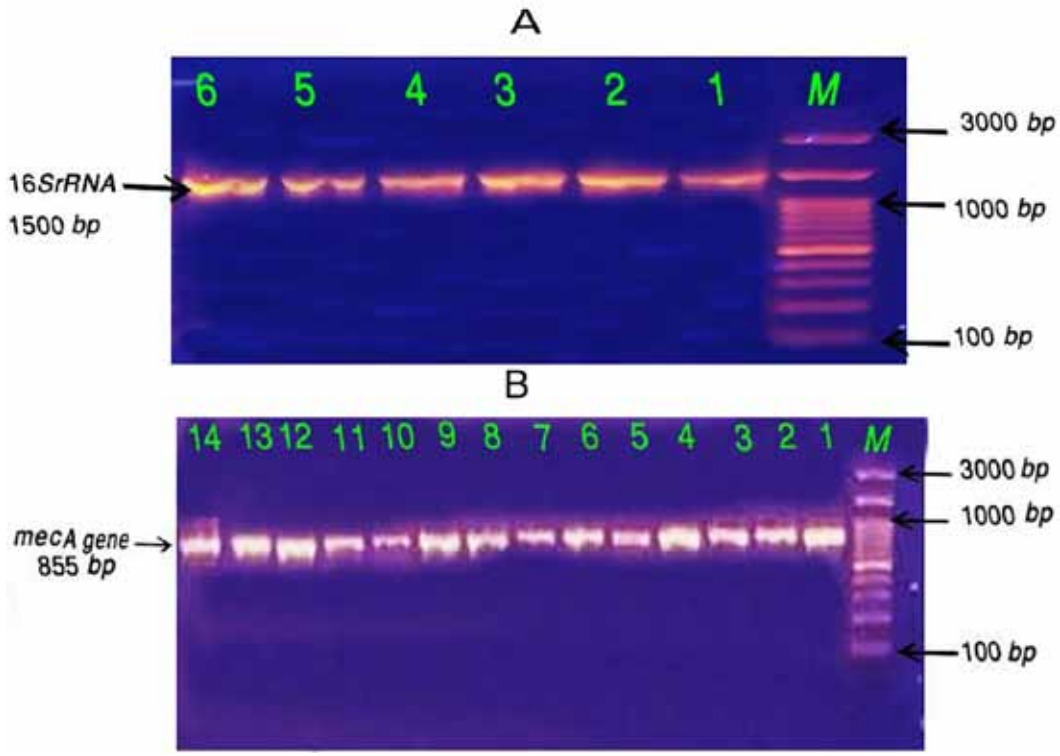

Figure 1 A: Agarose gel electrophoresis of 16SrRNA gene. M:3000 bp ladder; Lane [1-6] were positive with a product size of approximately 1500 bp. B: Agarose gel electrophoresis of *mec*A gene. M:3000 bp ladder; Lane [1-14] were positive with a product size of approximately 855 bp.

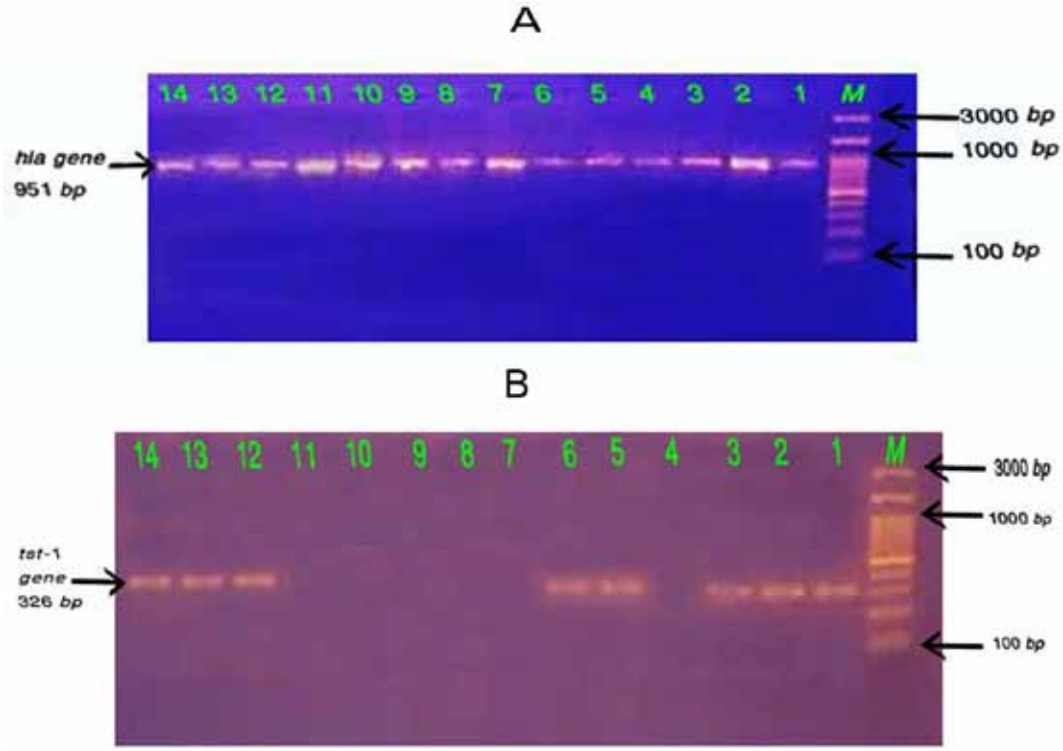

Figure 2 A:Agarose gel electrophoresis of *hla* gene. M:3000 bp ladder; Lane[1-14] were positive with a product size of approximately 951bp. B: Agarose gel electrophoresis of *tst*-1 gene. M:3000 bp ladder; Lane[1,2,3,5,6,12,13 and 14] were positive; Lane (4,7,8,9,10,11) were negative, the a product size of approximately 326 bp.

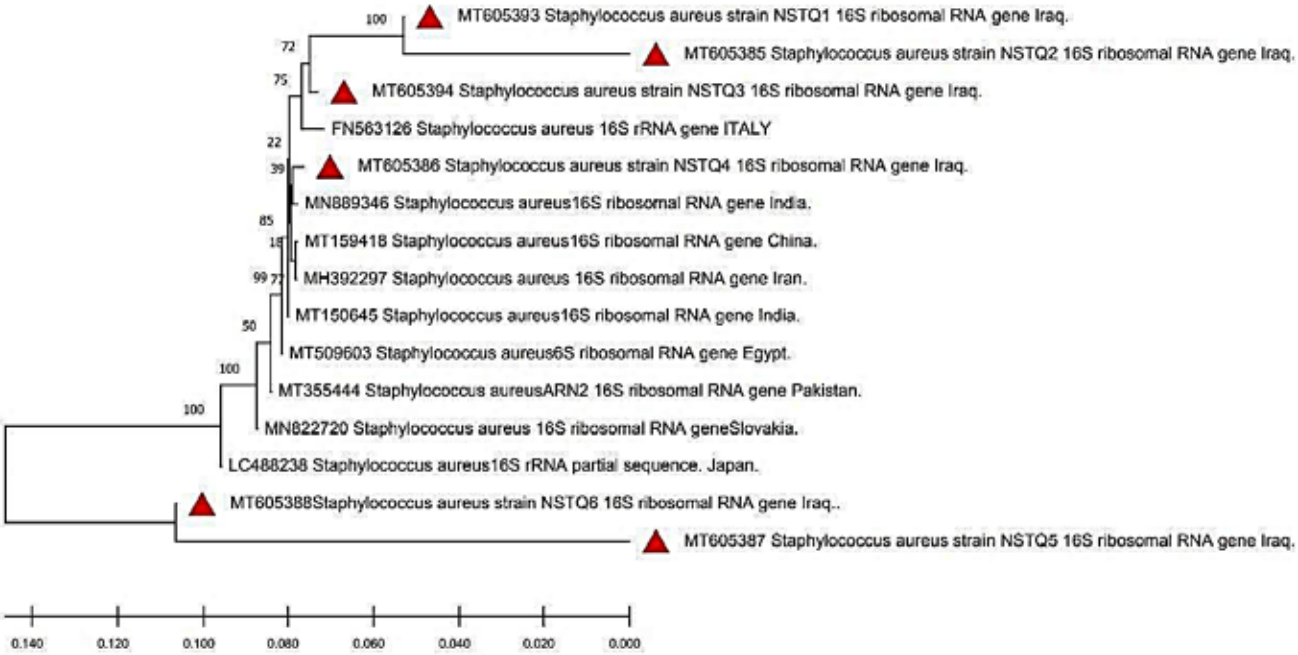

Figure 3: Phylogenetic tree analysis based on the (16sRNA) gene partial sequence that used for genetic relationship analysis of local *Staph. aureus*.

Discussion

Nosocomial infections, is an infection established at some point in hospital care which develops no longer present or incubating at the time of admission, the infections which arise further than 48 hours after admission are also taken into consideration nosocomial [9]. All MRSA isolates were diagnosed by PCR technique through the amplification of 16SrRNA and *mec*A genes to confirm that the verified isolates are *Staph. aureus* and MRSA, respectively. These results agreed completely with previous local studies like[10,11,12]. The drug resistance of MRSA is mainly because that the gene encoding regulates the expression of Penicillin Binding Protein (PBP2a), which is encoded by *mec*A gene, and arisen on the surface, which lies on the *Staphylococcus* gene cassette of SCC *mec*. Thus, the detection of *mec*A gene can be used to confirm diagnosis of MRSA isolates[13]. Other studies inside and outside Iraq revealed variable MRSA occurrence with a rates of 15% and 77.33%, respectively[14,15]. Different MRSA isolation among studies may be explained by the differences of samples or the different PCR assays. The current study tried to amplify *tst*-1 and *hla* genes as a virulence genes in MRSA isolates. All isolates of MRSA have *hla* gene which agreed with the local study of [16] who noted highly frequency of *hla* gene 70(82.35%) between MRSA isolated from burn patients. Other worldwide studies were closely compatible to the present results such as what performed in Uganda and united states whom recorded (100%) frequency of *hla* gene in MRSA isolates[17,18]. While, in Iran[19] results were incompatible with the current results who noted that frequency of *hla* gene was (51.8%). The highly frequent of *hla* gene maybe because that the most of *Staph. aureus*isolated from human have usually a *hla*, since the human platelets and monocytes are more subtle to the alpha toxin[20]. The current study revealed that a half of MRSA isolates contain *tst*-1 gene, which seems not supported with other similar local studies in Iraq who showed a variable frequency of *tst*-1 gene among MRSA isolates from clinical samples with 30% and 84%, respectively[21,22]. A closely related results to the present results were recorded in Iran who noted that frequency of *tst*-1gene was (51.4%) among MRSA isolates from intensive care units patients [23]. The relatively high rate of *tst*-1 positive *Staph. aureus* isolates coupled with the low incidence of TSS strongly suggests that sufficient *tst-1* expression causes disease only under the appropriate environmental and/or genetic regulation control. Since the virulence of microbe may be dependent on the amount of toxins production [24]. Sequencing technique is one of the modern advanced development technique in molecular biology. In this way mutation and genetic relationship can be detected between bacterial isolates

rapidly[25]. The DNA sequencing analysis results for 16SrRNA *Staph. aureus* gene isolates were genetically identical by 99% with those found in the gene bank. Six isolates are shown for the 16SrRNA gene genetically far from the genes taken from the gene bank because they appeared in the out-group. The phylogenetic tree showed that there were different molecular relationships among the local *Staph. aureus* isolates with analogous ones around the world (Fig. 4).

Conclusions

Methicillin-resistance *Staphylococcus aureus* (MRSA) were increased and become more prevalent, the molecular assay and gene sequencing were a significant tools in pathogenesis and evolutionary relationships of nosocomial infections.

Ethical Clearance: The Research Ethical Committee at scientific research by ethical approval of both environmental and health and higher education and scientific research ministries in Iraq

Conflict of Interest: The authors declare that they have no conflict of interest.

Assessment of Health Workers Knowledge toward Occupational Health and Safety Program in Alkut City's Primary Health Care Centers

Duaa Malik Dhahir[1], Naji Yasser Al Mayahi[2]

[1]M.Sc. Student, Nursing College, University of Babylon,
[2]Assistant professor Community Health Nursing, Nursing College, University of Babylon

Abstract

Health care workers are always exposed to physical, chemical, psychological and biological agents that affect their health. Regular information is serious for setting priorities necessary to enhance providers, health and safety, which healthcare facilities like other high danger workplaces are categorized by a high level of exposure to hazards agents, which significant danger toward health of workers.

A descriptive cross sectional study is carried out throughout (1/September/2019 to 1/September/2020) in order to assess the Health Workers Toward "Occupational Health and safety program" and to find out the relationships between knowledge's of health workers toward occupational safety and health program and their socio-demographic.

The study findings indicate that there is a significance relation among health worker's knowledge about occupational health and safety program with their level of educational and their age. As well as findings show that there is a highly significance relation between knowledge about occupation health and safety program with the training of course that health workers participatedin.

The study concludes that health workers Age, level education, training course, monthly income, and Number of years of Employment Have a great effect on occupational health and safety program.

The study recommends Encourage health care workers to attend continuing education activities in the form of workshops, conferences, training programs, refreshing courses and review update related to "occupational health and safety program" and ministry of Iraqi health could improve the infections protective processes as "head cap, closed shoes, gloves, and frequent medical examination for communicable diseases" as hepatitis.

Keywords: *Assessment, health care workers,Occupational Health and Safety Program.*

Introduction

Occupational safety and health (OSH) is a very important issue that must be taken into consideration in any working environment. For the avoidance of accidents, OSH rules and regulation should be implemented. Occupational health and safety is a specialty covering several specialized areas with a wide scope. In the broadest context, it should seek to: encourage and preserve the greatest level of physical, emotional and social wellbeing of staff in all professions; avoid working environments that could adversely impact employee safety and wellbeing; In recent years, major changes have taken place in workplace health and safety systems intended to prevent and monitor worries [1].

Occupational health is characterized as a multidisciplinary activity, as per the World Health Organization (WHO), aimed at: • the preservation and protection of workers ' health, the prevention and management of occupational hazards and injuries, and the removal of occupational causes and conditions that are hazardous to occupational health and safety. Creation and promotion of safe and stable jobs, workplace conditions and organizations at jobs. Improving the physical, emotional and social well-being of staff and

encouraging the growth and preservation of their ability to work, as well as personal and social development at work. Facilitating employees to live economically and socially prosperous lives and to make a meaningful contribution to their sustainable growth [2].

About 100 million workers in many countries are subject to some form of workplace health threats, such as carcinogenic agents, instances of pulmonary or other physical illness, physical agents, ornoise, crowding, or stress-related work-related stresses. Chronic respiratory disease, cancer, degenerative disease in a variety of critical organ systems, birth defects, and genetic changes may be associated with exposure to harmful contaminants or physical hazards. It is predicted that these exposures will "result in 100,000 Americans dying from occupationally associated diseases each year, and an additional 400,000 cases of occupationally related diseases"[3].

In addition to, Occupational hazards cause multiple forms of injury or disability. The loss of human resources, which can lead to reduced productive and service capacity and in some serious situations, may result in the death of the workers. Thus, leading to the loss of competent staff. Also, in developing countries, poor professional performance of health care providers may undermine the quality of health care institutions, particularly among nurses . Hospitals have many unique hazards that may possibly affect the health of workers. Risk exposure throughout the hospital unit is highly variable Exposure to chemicals can occur from disinfectants, sterilizers, cleaning compounds, an aesthetic gas, mercury, and hazardous drugs. Biological hazards include viruses that cause hepatitis B, C, HIV, TB (MRSA), methicillin-resistant staphylococcus aurous and latex sensitivity[4].

Psychosocial, physical, biological, chemical and ergonomic variables may be grouped as health-related hazards related to health professionals. 29 physical types, 25 chemical types, 24 biological varieties, ten and 6 types of ergonomic and psycho-social potential hazards have been identified by "the American National Institute for Occupational Safety and Health (NIOSH)"[5].

Ever since people started working, workplace safety and health have been a matter of concern. Occupational disorders affect the entire organ system, including "respiratory diseases, musculoskeletal injuries, traumatic injuries, cardio-vascular diseases caused by work, hearing loss triggered by noise, dermatological problems, and psychiatric diseases". Exposures to workplaces also contain airborne toxins, ionizing radiation, ultraviolet and visible light, and the workplace can also be a vector of a wide variety of infectious diseases, including HBV, tuberculosis (TB), influenza and AIDS (hepatitis B virus)[6].

Methodology

A descriptive cross sectional study is carried out throughout (1/September/2019 to 1/September/2020) in order to assess the Health Workers Toward "Occupational Health and safety program" and to find out the relationships between knowledge's of health workers toward occupational safety and health program and their socio-demographic. The study population included health workers who are working in Al-Kut City's primary health centers.

The reliability of the question instrument which is determined by a pilot study and the validity is accomplished by a panel of (12) experts. The total items which are comprised in the question are (25 item). These items are distributed in three parts which comprise Occupational Health hazards experienced by Nurses. This part consists of (general information, about Knowledge items regarding definition, types, common hazards of Occupational Health and Safety) which included (6) items, Occupational health control measures which included (9) items, and Preventive Measures for Occupational Health Hazards. Which included (10) items. The data collected on an individual base, the questionnaire was filled by health workers themselves under the researcher supervision and each self- report takes between (25-30) minutes. The results analysis are investigated through SPSS, which descriptive and inferential statistical data analysis approach that comprises, "frequency, percentage, mean, standard deviation; t- test, Chi-Square, and ANOVA test".

Results and Discussion

Table (1): The characteristics of participants showed 150 nurses; the majority of them was male These finding go along with study that conducted by Umar and code (2017) who found that most of participant were male.

Concerning Age, the most age 20 – 30 year was. This finding in the same line with study that carried out by Awan and others (2017) who found that the most sample their age between 26-30 years . Regarding marital status, highest the percentage of married couples were in marital status. These finding consistent with

Hamad and Qassim (2019) study who stated that most of sample were Married [4].

Concerning the educational level, the results are showed that higher percent was of high school nursing. These results incongruent with study that carried out by Hamad and Qassim (2019) who reported that higher percentage of study sample were Bachelor's degree. Regarding the Monthly income of nurses, the results of current study depicts that higher percent of participant was Satisfied . These finding go along with study that conducted by Hamad and Qassim (2019) who stated that monthly income about most of sample was about 601.000-900.000 Iraqi Dinar [ID]) and this consider satisfied [4].

Regarding the Resident area, the finding revealed that majority of them in Rural area. This results not in the same line with study that carried out by Jouda (2006) to explore the extent of the ergonomically hazards among the employees of the Ministry of health in the Gaza Strip, who found that Cities represent the large portion of total sample. While on other hand go along with study that carried out by Nabilandothers (2018)who found that majority of total sample belonged to rural these finding consistent with results of study under hand[7,8].

Table (2): The table shows preventive measures for occupational health hazards, higher percentage of participant their answer was right, while the mean of scores indicates to (1.597) the mean considers as moderate level.

The table(2) shows the overall occupational health hazards experienced by nurses, most of them their answer was right, while the mean of scores indicates to (1.511) the mean considers as moderate level. The total score mean of the knowledge of health care workers is 51.1%, which is considered as moderate knowledge levels. These results of study under hand at the same line with a study that carried out by Saqer (2014) who found that total mean of score was moderate level. This finding may be due the insufficient given that of adequate "training courses concerning dealing with risks through the work. The lack of continues follow up from the organizations of health and safety" in the health work situation that lead to create a chief problem and expose the health care workers to suchdangers [11].

Presents the items occupational and safety program, according to questionnaire; the findings indicate that mean scores are displayed to moderate level among all items. The finding of present study not in the same line with results of study that carried out by Abiodun and others (2018) he found when assess perception a knowledge of healthcare providers of job hazards in their work situation, also recognize their safety practices and them attitudes towards protecting themselves from hazards, who found that more than half of the respondents have good knowledge of occupationalhazards[12].

Table (3): Revealed that there is no statistical significant relation among subdomain's of questionnaire study and gender. at p=or ≤ 0.05, these findings go along with Abiodun and others (2018) who found there non association between gender and knowledge about occupational health hazards [12].

While that there is a significant association with subdomain's of questionnaire study and age at $p \leq 0.05$. these findings inconsistent with study that carried out by Ahmed (2019) who found that non-significant association among age with general knowledge on professional health and safety measures in originations health [13].

Table (4): Revealed that there is relationship among subdomain's of questionnaire study, Level of education .These findings consistent with study that carried out by Aluko and others (2016) who reported that there was, there is relation between the knowledge level and level of educational. Most of the respondents had at least high nursing school, that explains why the level of knowledge of occupational hazard is high and influenced by educational level. where it concluded that the level of education influences the health and safetyissues [14]. Concerning training course, that there is relationship among subdomains of questionnaire study at $p \leq 0.05$.

The results were displayed that there is no statistical significance "association" between subdomain's of questionnaire study and marital status. at $p \leq 0.05$. These findings congruent with study that conducted by Sabita and others (2018) who reported that no association among marital status with level of knowledge on occupational health hazards at p-value0.45 [15].

There is a significant association with subdomain's of questionnaire study and Income monthly at $p \leq 0.05$ this finding contrast with study that carried out by Alqam (2013) who reported that there are no significance difference at the level ($p = 0.05$) in the means of job hazards knowledge and perception, "Performance" Information, Safety measures, and satisfaction domain, according to monthlyincome[16].

A Comparative Study of Arch Width, Overjet and Overbite between Bilateral Congenital Missing Lateral Incisor and Normal Class I Occlusion

Zena Hekmat Altaee[1], Laith Hamood Aswad AL-Salmany[2], Maha Mishaal Turki[3]

[1]Ass. Prof., [2]Assist. Lect., Department of Orthodontics, College of Dentistry, University of Anbar, Iraq,
[3]Assist., Department of Prosthodontics, College of Dentistry, University of Anbar, Iraq

Abstract

Permanent lateral incisors have been considered as major missing teeth in the mouth. The main aim of the present study is to conduct a comparative study of maxillary and mandibular arch widths, overjet and overbite for a sample with missing lateral incisors and normal class I occlusion.

The sample of the study comprises sixty pairs of study models of both genders, which were separated into two groups. The first group consisted of thirty casts of bilateral congenital missing lateral incisors, while the second group consisted of thirty casts of the class I occlusion. The intercanine width, interpremolar width, intermolar width, overjet and overbite were measured for the sixty samples.

The results of this study demonstrate a significant reduction in maxillary and mandibular arch width in bilateral missing lateral Incisors as compared with normal class I group. The results also revealed a significant reduction in overjet and overbite in bilateral missing lateral incisors as compared with normal class I group. A significant difference was also reported between the two groups based on gender difference in the maxillary arch width. Conversely, non-significant difference was found in the mandibular arch width. The present study also shows non-significant difference based on gender difference in overjet and overbite in the two groups.

Keywords: *Congenital missing teeth, lateral incisors, Arch width, class I.*

Introduction

The missing lateral incisors has been considered as major congenital dental anomaly[1,2,3]. Missing teeth results in disturbances in developing occlusions, masticator verbal dysfunctions, and it affects aesthetics as well. Thus, a considerable number of associated consultants is required to cure such cases[4]. However, missing teeth etiology remains indefinite and requires more research. Nevertheless, it seems that a congenital missing tooth is thought to be strongly controlled by genes, and is associated with various syndromes[4]. It is commonly believed that upper lateral side incisors (excluding the third molar) are the most reported cases of missing teeth with incidence 5%[5-6].

Furthermore, the orthodontic treatments of patients experiencing bi-or unilateral congenitally missing lateral incisors has been considered as one of the challenges affecting the treatment plan. The two main alternates, the orthodontic close the space or open the space regarding the prosthetic replacements, might be comprising functions, periodontal health, as well as aesthetics[7].

Arch width discrepancy is an important diagnostic aid, which can expect the treatment outcomes of an orthodontic cases[8]. It is important for orthodontist to have information of the normal growth, dentition development, arch dimensions, and any variations from the normal[9].

The present study focuses on the study of maxillary and mandibular arch width, overjet and overbite of patients with bilateral missing lateral incisors and normal class I occlusion in both genders to identify differences in these two types of groups.

Materials and Method

In the present study, sixty patients we chosen either from a private orthodontic clinic, or from Orthodontic Department, Faculty of Dentistry, University of Anbar. Patients must be between (15-35) years of age, and their age mean was 26.3±0.3 years.

Care was taken to exclude the patients who have previous orthodontic treatment history, cleft lip and palate, serial extraction as well as history regarding the extraction of permanent teeth.

All the radiographs have been estimated on the dental viewer through one author to the patient. Furthermore, a tooth has been considered as congenitally missing lateral incisors in case no trace on radiograph is found. Treatment records were also checked to verify if the missing tooth was extracted or not. Impressions were taken by Alginate impression material and were poured by orthodontic plaster. All information about the patients ex. name, age, gender and radiograph were collected and attached to the records made for all patients.

Then the study sample was divided into two groups. The first group consisted of thirty pairs of patients with bilateral congenital missing lateral incisors equally divided between the genders (fifteen males and fifteen females), and the second group consisted of thirty pairs of patients with class I occlusion based on a class I skeletal relationship without any abnormality to be the control group of this study. These were also divided equally between the genders (fifteen females and fifteen males).

Measuring Technique: Measurements were made on the upper and lower study model by a single examiner using ecteronic digital caliper with sharpened tips which records up to 0.01 mm. The dental arch width was recorded by measuring intercanine width, interpremolar width, intermolar width, overjet and overbite.

The reference points for the measurements were marked by using the sharp-pointed pencil to create the exact landmark points. The reference points that were used as landmarks are presented as follows and as shown in (figure 1):

1. Intercanine width: The distance between the cusp tips of the maxillary right permanent canines and left permanent canines.
2. Interpremolar width: The distance between the first premolar of the left side to the right side at the distal end of its occlusal groove.
3. Intermolar width: The distance between the maxillary first permanent molars of the left side to the same of the right side at the central fossae on the occlusal surface.
4. Over jet: The extent of horizontal overlap of the maxillary central incisor over the mandibular central incisor.
5. Over bite: The extent of vertical overlap of the maxillary central incisors over the mandibular central incisors.

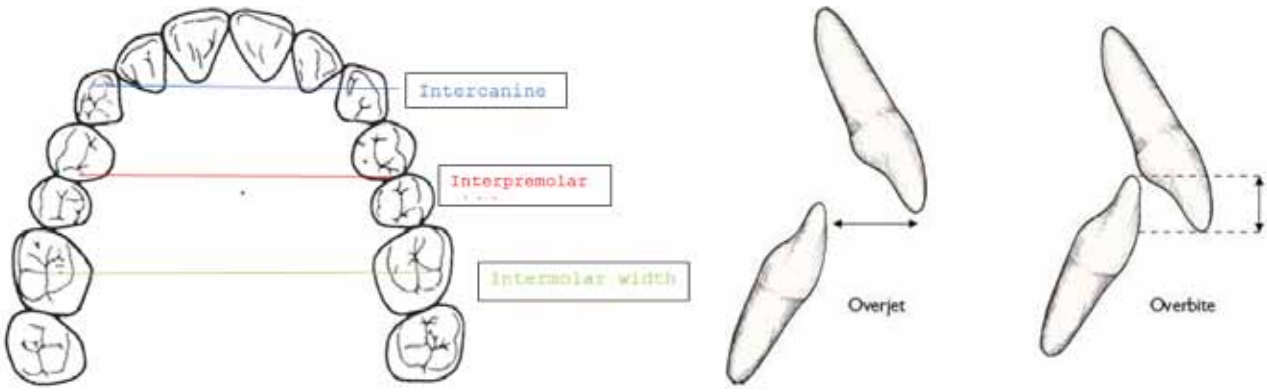

Figure 1: The landmarks used in this study

Statistical Analysis: The data were collected then statistically analyzed using SPSS software version 25 to calculate means and standard deviations of quantitatively collected data. The difference between the two means was identified using (t) test. The significance among means was calculated at $P<0.05$ critical level.

Reliability Test: The distance of twenty pairs of study models were measured randomly. After three weeks, the measurements were repeat to determine the reliability of the measurement by using intraclass correlation coefficient test, which showed excellent reliability (> 0.90).

Results

The chronological age range of the sample was (15-35) years. Table (1) displayed the results including the comparison of arch widths between bilateral congenital missing lateral incisors (BCMLI) with Class I normal occlusion in maxillary arch. The results indicated a significant difference between maxillary arch widths in both groups ($p<0.05$).

The comparison of arch widths between bilateral congenital missing lateral incisors (BCMLA) with Class I normal occlusion in mandibular arch is shown in the Table (2).

There was a significant difference in mandibular arch widths in both groups ($p<0.05$); however, intermolar distance shows non-significant difference ($p > 0.05$).

As shown in Table (3), there is highly significant reduction in overjet and overbite (≤ 0.001) in the bilateral congenital missing lateral incisors (BCMLA) when compare with normal class I occlusion.

Based on the results tabulated in (4), there was a significant variance between male and female in two groups ($p < 0.05$) in terms of the intercanine width, interpremolar width and intermolar width in the maxillary arch.

Conversely, non-significant difference $p>0.05$ in terms of intercanine width, interpremolar width and intermolar width in mandibular arch was revealed.

Table (4) demonstrates non-significant differences ($p>0.05$) according to gender in overjet and the overbite in the two groups.

Table (1) Illustrates the results of comparing arch widths between bilateral congenital missing lateral incisors (CMLA) and Class I normal occlusion in maxillary arch

Variable		BCMLA	Class I	P. value
Intercanine Width	Mean	26.32	30.11	0.001**
	S.D.	0.8	1.32	
Interpremolar Width	Mean	33.7	36.5	0.045*
	S.D.	1.6	1.32	
Intermolar Width	Mean	42.47	47.81	0.037*
	S.D.	1.8	1.26	

*Significant at $P < 0.05$., **Highly significant at $P \leq 0.001$

Table (2) Shows the comparison of arch widths between bilateral congenital missing lateral incisors (CMLA) with Class I normal occlusion in mandibular arch.

Variable		BCMLA	Class I	P. value
Intercanine Width	Mean	23.14	27.89	0.035*
	S.D	1.32	0.71	
Interpremolar Width	Mean	31.6	32.4	0.028*
	S.D	0.78	0.91	
Intermolar Width	Mean	40.87	43.2	0.069
	S.D	1.24	0.79	

*Significant at $P < 0.05$.

Table (3) Shows the comparison of overjet and overbite between bilateral congenital missing lateral incisors (BCMLA) with Class I normal occlusion.

Variable		BCMLA	Class I	P. value
Overjet	Mean	1.98	3.1	0.001*
	S.D.	0.81	0.68	
Overbite	Mean	0.89	2.11	0.001*
	S.D.	0.56	0.81	

*Highly Significant at ≤ 0.001.

Table (4) Reports gender effect results on bilateral congenital missing lateral incisors (BCMLA) with Class I normal occlusion.

Variable	BCMLA		P. value	Class I		P. value
	Female Mean SD	Male Mean SD		Female Mean SD	Male Mean SD	
Max. Intercanine	28.54	30.12	0.034*	31.76	32.8	0.025*
Width	1.98	0.67		1.92	2.12	

Max. Interpremolar	34.14	36.7	0.00**	35.8	38.1	0.01*
Width	1.87	1.67		1.97	2.65	
Max. Intermolar	41.1	43.1	0.04*	44.5	48.12	0.001**
Width	0.87	1.54		1.78	2.34	
Man.Intercanine	22.46	24.34	0.082	26.5	28.45	0.091
Width	0.32	0.76		1.32	0.65	
Man.Interpremolar	30.8	31.78	0.067	32.1	32.98	0.075
Width	0.87	0.43		0.67	1.34

Width	0.78	1.25		1.34	1.82	

*Significant at $P < 0.05$., **Highly significant at $P \leq 0.001$.

Discussion

The congenital missing teeth occur due to disturbance during the initial stage of tooth formation and proliferation. Missing one tooth or more is considered one of the most common developmental anomalies. Moreover, the most common missing type is the bilateral missing lateral incisors[10].

A significant reduction in the arch width between bilateral congenital missing lateral incisors and normal class I occlusion in the maxillary arch was revealed in this study. This could be due to the decrease in the number of the teeth, which in turn causes a reduction in the width of the maxillary arch[11,12,13].

In the mandibular arch, there was a significant reduction in the intercanine and interpremolar width, but non-significant reduction in the intermolar width was reported the cause of that the missing of the lateral incisors leads to make the canine erupted more mesially than the normal occlusion. This in turn leads to more deficiency of the width of intercanine and interpremolar width[14].

There was a significant reduction in overjet and overbite in bilateral congenital missing lateral incisors compared to normal class I occlusion. This result agrees with that obtained in [15,16], who found that the missing of lateral incisors leads to retroclination of the upper and lower incisor, and thus results in an increase in interincisal angle and more uprighting incisors appearing in the missing lateral incisors patients.

The maxillary arch was significantly greater in males than females in the two groups. This finding is also in agreement with[14,15,17,18,19]. This could be due to smaller and smoother bony ridge, the alveolar process of female, or due to weakness of musculature in female[20]. This result is not in line with the results obtained by[21,22], who found non-significant differences between males and females. This inconsistency could be due to using different landmarks, different sample size, age group, ethnic group and procedures.

The majority of the dental arch widths in mandibular arch revealed non-significant difference between males and females. This agrees with[23,24], but disagrees with[18,19,20]. The difference might be due to racial factor or the difference in the analyzing technique employed.

This study shows non-significant differences based on gender difference in overjet and overbite in the two groups. This result agrees with[24,25,26]: yet, it disagrees with[27,28].

The present study is important to the orthodontist to decide the most appropriate treatment plane to adopt in treating patients with bilateral congenital missing lateral incisors by open or closed the space with maintaining good esthetic to the patient by providing a correct arch width, overjet and overbite. [29]

Conclusions

The results indicated a significant reduction in arch width in maxillary and mandibular arch in bilateral missing lateral Incisors when compared with normal class I occlusion group.

There was a significant reduction in overjet and overbite in bilateral missing lateral Incisors as compared with normal class I group.

There was a significant variation between males and females in the two groups in the maxillary arch width. However, non-significant differences were reported in the mandibular arch width.

This study showed non-significant differences based on the gender difference in the overjet and overbite in the two groups.

Application of Fractional Co2 Laser Modification of PEEK in Dental Implants, *In vivo* Study

Nahida Zahir Kamil[1], Basima Mohammed Ali Hussein[2]

[1]M.Sc. Student, [2]Assist. Prof., University of Baghdad, Institute of Laser for Postgraduate Study

Abstract

This study aimed to Modify the PEEK surface using Fractional CO2 laser in different range of parameters to change the surface topography regarding roughness and wettability to enhance osseointegration. A PEEK block (Ceramill PEEK 98X20 N -JUVORA dental innovations, UK) was used to prepare substrate. By CAD-CAM system, PEEK was cut into discs (2 mm thickness and 10 mm diameter). the discs were smoothed by silicon carbide paper of 500 grit and a rotation motion, polishing machine at 200 rpm for one minute used to polish the discs, finally cleaned with ethanol alcohol using ultrasonic cleaner. Different parameters were tested to study their effects on PEEK surface; therefore, several trails were done using Fractional CO2 laser device. Surfaces of the irradiated PEEK discs were examined microscopically at different magnification power. Then SEM was used. Then, PEEK samples were scanned by (EDS). Range of powers were used (2, 4, 6, 8, 10, 12) W The distance between spots was 0.2mm and 0.2 ms pulse duration to ensure maximum coverage of laser effect. The energy range was (4 - 25) which was n't enough to produce any effect. To test the effect of pulse duration different values were also studied starting from 0.2ms then increase the pulse duration. 0.4,0.6,0.8 ms to increase the energy per pulse accordingly. Starting from short pulse duration up to 0.6ms there was no effect even when the power increased. At 0.8 ms pulse duration, the effect was recognized on the specimen surface. The collected data of previous trials direct the operator to reduce pulse duration to have best criteria, including surface roughness, wettability, without carbonization or cracks.

Conclusions: Successful modification of PEEK surface can be done with fractional CO2 laser. Laser parameters as power, pulse duration, distance between spotes and number of scans are key factors induced different range of effect considering material's properties.

Introduction

Dental implants serve as artificial roots for the fixation of dental prostheses. By restoring the masticatory function through dental implants, the quality of life and nutritional status of the affected patients can be markedly improved**.** Osseointegrated dental implant was described as structural and functional connection between living bone and the implant's surface, under light microscope(1). In spite of well evidence- based implants made from titanium and titanium alloy,, it was observed that their usage can be associated with a variety of disadvantages, such as its light transmission lack, titanium can affect esthetic results**.** In cases of high smile line this can cause a darkness in neck of the periimplant soft tissue with thin gingival biotype or/and recession of gingivae surrounding a titanium implant . Also, hypersensitivity to titanium and other problem could occur because of the gradient difference in the titanium implant's elastic moduli and the bone surrounding it(2). As a substitution to titanium, implants made from ceramics were suggested Dental implants made from zirconia, were biocompatible, tooth like-color, and low plaque affinity, which appeared to be a better convenient substitution to titanium **.** But, because of higher elastic modulus of zirconia than the bone, might result in higher peaks stress in comparison to titanium**.** Other biocompatible material closer in modulus of elasticity of bone, is polyetheretherketone (PEEK)**.** PEEK is a thermoplastic polymer with a high-performance capable of replacing components of metallic implant in the field of orthopedics**.** With such findings encouraged the suggestions for PEEK to be substitution for titanium as

dental endosseous implants' material[3]**.** However the radiolucency and the good wear resistance of PEEK are advantageous for many orthopedic applications also it can be imaged by X-ray, CT scan, or MRI without any distortion in comparison to the conventional titanium (Ti). In spite of these superior properties, PEEK is still classified as bioinert because of its much decreased reaction with the surrounding tissue, which restricts its potential applications **.** For overcoming this problem, many method have been suggested which can broadly be divided into two main categories: incorporation of bioactive materials and surface treatment techniques such as laser surface modification[1]. Laser treatments are used because of the resolution is high, speed of operating is high, and the bulk properties of implant will not be changed by the laser**.** That's why, lasers were introduced to improve implant. The CO2 laser of wavelength 10600 nm with an advanced technique referred to as a factional CO2 laser, it deliver the energy in parallel vertical columns of multiple microscopic thermal spots called microscopic treatment zones (MTZs), while the distance between spots remains intact and untreated[4]**.**

Aims of the Study: Modification of PEEK surface using Fractional CO2 laser in different range of parameters to change the surface topography regarding roughness and wettability to enhance osseointegration.

Materials and Method

Sample Preparation: PEEK block (Ceramill PEEK 98X20 N -JUVORA dental innovations, UK) was used to prepare substrate . By CAD- CAM system, PEEK was cut into discs (2 mm thickness and 10 mm diameter). To have a uniform smooth surface for standardization, the discs were smoothed by silicon carbide paper of 500 grit and a rotation motion, polishing machine at 200 rpm for one minute used to polish the discs, finally cleaned with ethanol alcohol using ultrasonic cleaner.

Laser Irradiation: Laser irradiation was done at Institute of Laser for post graduate studies/University of Baghdad considering all safety requirements. Different parameters were tested to study their effects on PEEK surface; therefore several trails were done using Fractional CO^2 laser device Figure (1).

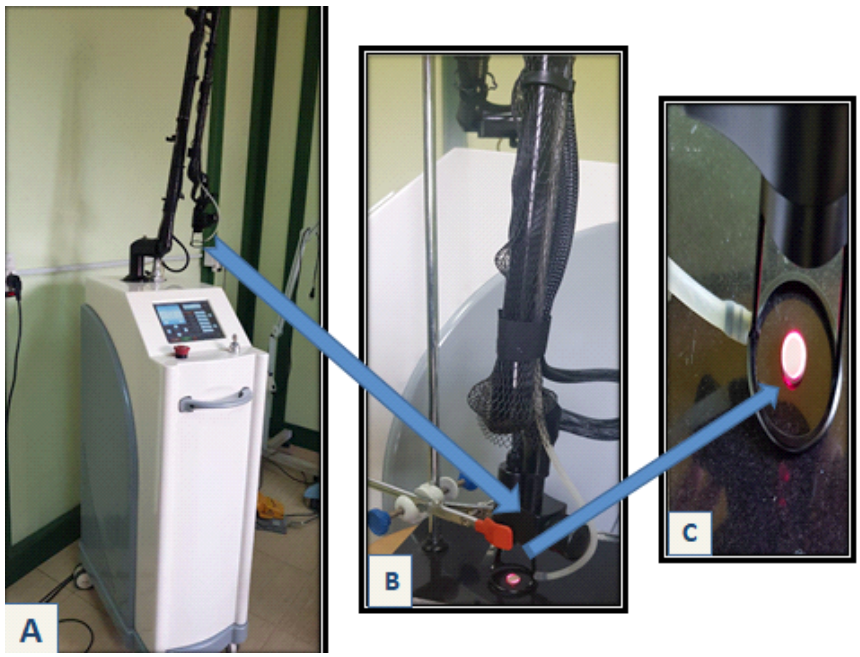

Figure (1): (A) fractional CO^2 device. (B) Articulating arm of laser device (C) PEEK disc ready for laser irradiation

During irradiation, the arm of the laser device was fixed using laboratory clamp and PEEK specimen was set on a stage at fixed distance between the beam source and the specimen surface in-----cm.

Light Microscope: Surfaces of the irradiated PEEK discs were examined microscopically at (4,10, 20 and 40X) magnification powers using light microscope (BX51/OLYMPUS).

Scanning electron microscope (SEM): Laser irradiated samples were scanned by SEM (Oxford instruments, UK) to see the difference on the surface topography.

Atomic force microscope (AFM): Surface roughness was assessed by atomic force microscope (AFM) for the irradiated and non-irradiated samples.

Energy-dispersive X-ray spectroscopy (EDS): PEEK samples were scanned by (EDS) (Oxford instruments, UK) for surface analysis and to calculate the percentage of elements formed on the surface of the irradiated and non-irradiated samples.

Contact Angle: Wettability test was conducted using contact angle measuring device (Creating Nano Technologies Inc., Taiwan). The specimen was placed on adjustable table and micropipette dropper was used to dispense a drop of normal saline in 6.89 micro liter volume. The distance between the dropper tip and specimen surface was 4 mm.

Results

1. Range of powers were used (2, 4, 6, 8, 10, 12) W The distance between spots was 0.2mm and 0.2 ms pulse duration to ensure maximum coverage of laser effect. The energy range was (4 - 25) which was n't enough to produce any effect.
2. To test the effect of pulse duration different values were also studied starting from 0.2ms then increase the pulse duration. 0.4,0.6,0.8 ms to increase the energy per pulse accordingly. Starting from short pulse duration up to 0.6ms there was no effect even when the power increased. At 0.8 ms pulse duration, the effect was recognized on the specimen surface.
3. Considering the result from previous trials an attempts were carried out regarding distance between spots,duration and scans. Then decision was made to increase the distance (0.2, 0.4, 0.6mm,….) to reduce heat accumulation, And as shown in figure (2) different powers were tested with 0.4mm distance and 1ms duration which produce deferent effects with sign of carbonization in most trails.

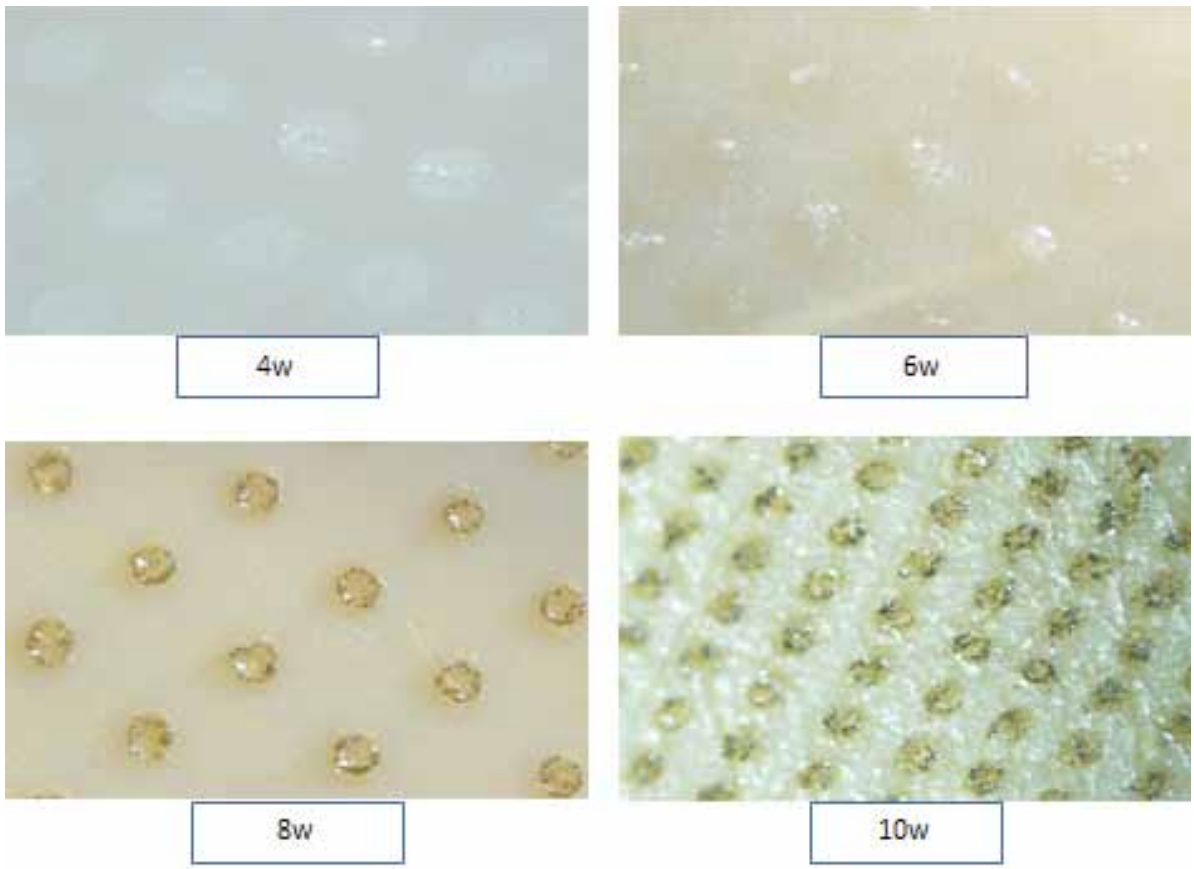

Figure (2): Light microscope image of PEEK specimen treated with 0.4mm distance, 1ms duration and 1 scan. (10 X).

4. The collected data of previous trials direct the operator to reduce pulse duration to have best criteria, including surface roughness, wettability, without carbonization or cracks. The effect for specimens irradiated under 6W power shows interaction without carbonization, this also confirmed with SEM. Increased power (W) does not improve the result, in fact carbonization was clearly appeared with SEM.

Discussion

Numerous method have been used to modify the surface wettability, such as Fractional CO2 laser treatment because laser treatment can be used to target specific areas with higher precision,restriction manual movement of the hand piece during operation and the pattern which can be achieved is homogenous[5].

Wettability results agreed with[6] who concluded that the contact angle analysis showed a reduction in water contact angle with increasing laser power intensity, and the derived surface free energy increased accordingly . Different method of surface modification enhance wettability this is agree with [7].

For surface physical properties of dental implant materials, the surface with a certain degree of roughness is essential for the formation of bone implant interface[8,9]. In many ways, laser has been considered a new tool to process material surfaces because of its high efficiency and accuracy.

First of all, the rough surface is beneficial for the adsorption of organism protein and mineral. Second, the adhesion, migration, proliferation, differentiation, protein synthesis, and mineralization of osteoblasts on the materials surface were also promoted because of the increase in surface roughness[10,11]. In addition, the increase in surface roughness can expand the contact area between implant materials and bone and make the formation of locking effect at the bone implant interface. Finally, the bonding strength of the bone implant interface can be improved by forming rough surfaces[12,13].

Conclusions:- Successful modification of PEEK surface can be done with fractional CO2 laser. Laser parameters as power, pulse duration, distance between spotes and number of scans are key factors induced different range of effect considering material's properties.

Study of Verbal Bullying in Early Adolescents (Case Study of Pallangga 5 Junior High School and Sungguminasa 3 Junior High School)

Muh. Asrul Taufiq Arifuddin[1], Suriah[2], Sudirman Nasir[2], Muhammad Syafar[2], Lalu Muhammad Saleh[2], Nurhaedar Jafar[2]

[1]Master Degree of Public Health Student, Faculty of Public Health, Hasanuddin University,
[2]Lecturers of Faculty of Public Health, Hasanuddin University

Abstract

Bullying can take many forms, one of which is verbal bullying in the form of reproach, slander, cruel criticism, personal or racial insults. This study aims to examine the incidence of verbal bullying that occurs in early adolescents at Pallangga 5 Junior High School and Sungguminasa 3 Junior High School, Gowa Regency. This research uses a qualitative case study approach. Data was obtained through Focus Group Discussion (FGD), in-depth interviews with 59 informants and document review. Content analysis is used to identify topics or categories in the data. The results showed that the forms of verbal bullying varied, ranging from harassing, threatening, using verbal abuse by making fun of parents and the name of the victim. Therefore, schools should intensify the activities of the ambassador team so that verbal bullying can be minimized and teachers need to add insight into verbal bullying.

Keywords: *Study, Verbal Bullying, Early Adolescence.*

Introduction

Research on bullying began more than 40 years ago[1]. Bullying is aggressive behavior that is unwanted by other adolescents who are not siblings that involves a recurring imbalance of perceived power that causes physical, psychological, social or educational[2,3], both between the victim and the perpetrator. Bullying is characterized by physical, social, or verbal abuse affecting large numbers of school children worldwide[4]. Bullying at school is an act of repeated aggression and is deliberately directed at students who have little position or power[5]. Therefore, learning in schools must be conducive, safe, and comfortable and away from actions that endanger students. The central government, local governments, and other state institutions are obliged to guarantee a sense of security for themselves and the souls of students in their growth and development[6].

The bullying that is rife in schools can be done by teachers to students, students to other students and a group of students to other students. UNICEF reports that in 2015 violence against children occurred widely in Indonesia, 50% of children were bullied at school. Meanwhile, WHO data for September 2016, 12% of children in the world experienced sexual violence in the past year, even 37% of WHO member countries implemented interventions to prevent incidents of sexual violence on a larger scale. Meanwhile, the Indonesian Child Protection Commission (KPAI) released the results of monitoring cases of violations of children's rights in the education sector during 2019 which showed that acts of bullying or bullying of children against teachers increased drastically. From January to April 2019, bullying was dominated by bullying in the form of physical violence, psychological violence, and sexual violence. In addition, KPAI recorded 12 cases of psychological violence and bullying and 4 cases of children bullying their teachers. The majority of cases

Corresponding Author:
Muh. Asrul Taufiq Arifuddin
Master Degree of Public Health Student, Faculty of Public Health, Hasanuddin University,
e-mail: muhasrultaufiq097@gmail.com

occurred at the primary school level, reaching 25 cases or 67% of the total cases.[8].

Bullying can take many forms, including physical, verbal and mental. Bullying [9] ranges from verbal assaults (eg name calls, threats), physical behavior (eg hitting, kicking, damaging the victim's property), and social aggression (eg social exclusion, spreading rumors) to the latest forms of attack via the Internet and new technology (cyber bullying). This bullying behavior often occurs in school environments such as toilets, canteens and parks. In the context of this research, the researcher discusses verbal bullying. This type of bullying is very easy to find and occurs everywhere, such as acts of cursing, ridiculing, gossiping, making fun of and dwarfing, whether in the context of being intentional or not, joking or serious. This type of bullying can occur both in the family environment, in association, and even worse in the educational environment.

Observations on February 6, 2020 show that researchers obtained information from two State Junior High Schools in Gowa Regency who often engage in verbal bullying. From 2017 to 2019, in the case study at Pallangga 5 Junior High School there was verbal bullying of 4-5 people per class for at least one week. The trigger is a trivial thing, for example a student's pen is picked up by a classmate who is so angry that they keep laughing at each other's names. Meanwhile, at Sungguminasa 3 Junior High School, there are about 30 victims of bullying every year. Ironically, the perpetrators and victims come from people who are weak, easy to control and don't want to fight back. On January 27, 2020, an interview with a psychologist and consultant at the Integrated Service for Women's Empowerment and Child Protection, South Sulawesi Province obtained information on whether the training materials were designed with UNICEF support.

As a result, to form student facilitators, use the u-report platform to evaluate the school situation in cyberspace based on social media to conduct anonymous polls. In this way, at Pallangga 5 Junior High School and Sungguminasa 3 Junior High School, 74% of students were found to be bullied, an average of 4 to 5 times a week. Types of bullying include being hit, blackmailed, teased, chatting, and being bullied online. The learning facilitator works with students to change negative behavior into positive behavior, helping students develop their own exercise based on problems at school. Activities that can be carried out include making posters, editing work plans for tackling bullying in schools, and modeling positive behavior.

The form of verbal bullying that occurs is adjusted to the conditions of the language and the habits of the local community, for example calling the names of their parents in a mocking tone to saying obscene words and hinting at their friends, for example sundala children (illegitimate children), ka'bulamma, asu '(dogs). The words are considered normal and come spontaneously from the mouth of the bully. Verbal bullying includes humor and ridicule, name calling, shouting, verbal rejection, negative predictions, negative comparisons, humiliation, cursing and swearing, and threats to children. Verbal bullying uses endless cursing and ridicule the victim, usually judged by his physical inadequacy, as well as denouncing his stupidity and hobbies, ethnicity, religion, and overall physique. [11]

Although verbal bullying does not cause physical harm, it does have a negative impact on the victim's psychological side and poor social adjustment. Psychologically, for example, excessive anxiety, constant fear, depression, suicidal thoughts and symptoms of post traumatic stress disorder. Meanwhile, the victim also had difficulties in adapting to the social environment, for example wanting to move to another school or leaving that school, having disrupted academic performance or often deliberately not attending school. Another characteristic of victims of verbal bullying is a relatively low level of self-confidence which is caused by continuous insults, threats and inappropriate words to the victim or the perpetrator does not want to acknowledge the victim's physical and non-physical strengths, causing fear, loss of self-confidence and the ability to act. In addition, embedding with ugly titles, fat, dwarf the victim by gossiping or vilifying. Another impact is that children's development is socially and emotionally stunted where children can grow up with low self-esteem and low self-concept.

When they grow up, they are more likely to continue to be victims of verbal bullying, or to turn into verbal bullies. They also have a higher tendency to behave aggressively and to engage in delinquency and self-destructive behavior, such as drug use, alcohol abuse to attempted suicide. Victims of verbal bullying can also grow up to become personal with various kinds of psychological disorders, such as anxiety disorders, depression and emotional instability.

It often happens that students who are victims of bullying tend to be shunned and isolated so that victims of bullying tend to carry out negative coping strategies such as truancy, violating school regulations, and being individual, and falling into promiscuity as a form of escape to problems that the victim of bullying cannot yet solve. In addition, the public's misperception of bullying which is considered normal will unconsciously cause negative views on children who are victims, including being gloomy, lazy to study, skipping school more often, and being ignored and ostracized by the surrounding environment.

This is of course a serious concern from various parties, but on the other hand, teachers or parents tend to understand or add negative labels or attributes to the victims of bullying. Therefore, the school has made efforts and actions so that verbal bullying does not happen again in the form of advice and lectures both on Friday worship, during flag ceremonies, every lesson hour is empty and every time learning starts even makes posters containing verbal bullying stops.

Based on the empirical facts above, the problem of verbal bullying is interesting to study in the context of research. Remembering verbal bullying will have a negative impact on early adolescence. Early adolescents according to Erickson[12] are adolescents whose age criteria are 13-15 years old in girls and 15-17 years old in boys. According to WHO [13], the age limit for adolescents is 12 to 24 years.[14] Adolescents in these early days are still amazed at the changes that take place in their own bodies and the impulses that accompany them. They develop new thoughts, are quickly attracted to the opposite sex, and are easily sexually aroused. Excessive sensitivity coupled with reduced control (self-control) over the ego makes early adolescence difficult for adults to understand. This is in line with the theory of Low Self-Control[15] which assumes that one of the causes of criminal behavior is low self-control and even associates the phenomenon of bullying with social criminal behavior and considers it a serious problem in relation to student safety in schools and threats to academic achievement. In addition, students who are raised in a family environment and authoritarian parents can also cause children to behave deviantly.

Based on the description above, education today can run well without any form of violence, so that a peaceful atmosphere is created and learning can take place well. Therefore, the authors would like to carry out a study entitled "Study of Verbal Bullying in Early Adolescents (Case Studies at SMP Negeri 1 Pallangga and SMP Negeri 3 Sungguminasa." This study aims to examine the incidence of verbal bullying that occurs in early adolescents in SMP Negeri 5 Pallangga and SMP Negeri 3 Sungguminasa, Gowa Regency.

Materials and Method

This research design uses a case study approach to understand the problem of verbal bullying in depth and identify cases of verbal bullying that are rich in information. The research was conducted at Pallangga 5 Junior High School and Sungguminasa 3 Junior High School, Gowa Regency, South Sulawesi Province. Research informants were selected by purposive sampling based on predetermined criteria with complete elaboration in order to obtain maximum results. The data collection technique used secondary data from the Integrated Service for Women Empowerment and Child Protection, South Sulawesi Province, while the primary data was obtained from observations, Focus Group Discussions (FGD), in-depth interviews, and document review. Data analysis uses content analysis or content analysis which is interpreted and presented in the form of a narrative, matrix and schema.

Results and Discussion

The researcher will descriptively describe the form of verbal bullying by quoting the results of in-depth interviews and FGDs from a number of informants who have been determined. Various opinions of informants regarding the forms of verbal bullying that occurred at Pallangga 5 Junior High School and Sungguminasa 3 Junior High School,GowaRegency . Forms of verbal bullying that have occurred in both schools are ridicule, seniority behavior between seniors and juniors, thuggery, and bullying that students often face. Something that is more serious is done by students who are bullies in the form of threats to their friends when they are not given, which results in humiliation of the physical form of the body.

Forms of verbal bullying can be ridicule, physical actions taken by students. Say, there are seniors and juniors where seniors are salt, big and so on. It can put pressure on the juniors. Actions like this are often done by others when interacting. Also thuggery because of the presence of seniors and juniors in it, there can be bullying that students often face. Both students from within the school and alumni who have finished and still

have interaction with the school. Say they are already in high school but they still want to create old habits by blocking them outside the school environment such as doing bullying and so on.

(JA, 58 Years, 25 June 2020, 09.00 AM)

Triggered by trivial things such as being dwarfed/ mocked by calling the victim as his parent, being insulted because of his dwarf physical form, and so on. The forms of cases of verbal bullying that have occurred are mocking his friend, insulting his friend's physical form, threatening if the perpetrator asks for pocket money from his friend and is not given him.

(FM, 50 Years, 17 June 2020, 10.00 AM)

It was revealed that the form of verbal bullying that was carried out by students was in the form of taunts, physical actions that were part of the seniority system that still prevailed at school and continued to build communication with students who were inside the school by creating old habits from school time by blocking them outside the school environment such as bullying. and so on so that it leads to threats and humiliation of the physical form of their friends that students often face. In the FGD, the student perpetrator said that he often made fun of and changed his friend's name to the name of his parents, gave bad words and even insulted, ordered him to and fro and hid his friends' belongings. The counseling teacher and homeroom teacher revealed that mocking and insulting the physical form of friends, calling parents' names, bullying and threatening friends when their wishes were not fulfilled, which was often done by the perpetrator, was revealed in the results of the interview below:

Forms of verbal bullying that have occurred include mocking his friend, insulting his friend's physical form, threatening if the perpetrator asks for pocket money from his friend when he is not given him.

(HA, 41 Years, 26 June 2020, 10.00 AM)

For example, at school, students call their friends not their names but the names of their parents. For example, his name Aswan is called Dg. Beta because his parents are named Dg. Beta or physically he was ordered to go shopping. So, children are forced to do not because of desire but because of fear. Or something is being interrogated by a friend.

(TA, 44 Years, 17 June 2020, 13.00 PM)

Harass or threaten his friend to submit with harsh verbal such as "puppy or" sundala "(illegitimate child)". **(MI, 36 years old, 27 June 2020, 10.30 AM)**

Yes, that was mocking his friend with words about his physical condition like if he is black, he is called black, if he is "frizzy" maybe he is called "frizzy", maybe so. **(HL, 57 Years, 18 June 2020, 10.00 AM)**

There are those who say, there are those who behave or act that makes other people uncomfortable with the behavior they do.

(SP, 50 years old, 18 June 2020, 12.00 PM)

The interview excerpt above, shows that the form of verbal bullying that occurs at school is mocking, insulting the physical form of the body, threatening friends if they are not given what they want, harassing or threatening friends to submit by using harsh words such as puppies or harasses haram), calling parents' names, nicknames that are made fun of, mentioning inappropriate words. Meanwhile, students who were victims of verbal bullying said that their parents' names were made fun of and called the victims not their names. In the FGD, the perpetrator student admitted that he often made fun of his friend by calling him not a friend, not his real name, calling the names of parents to the names of animals. Thus, it can be concluded that the form of verbal bullying that occurs refers to the act of expressing certain words or verbal words from the offender to offend his friend as a victim of verbal bullying.

This was also conveyed by the parents of the perpetrator students in the FGD who admitted that their children often made fun of, mocked, ridiculed, alienated their friends, and used verbal abuse between their children and victims. For parents of victim students based on the results of in-depth interviews with researchers about the form of verbal bullying experienced by their children, they are described separately and briefly as follows:

The forms of verbal bullying that children have experienced are being said by their friends instead of their names and making fun of their peers.

(HS, 33 Years, 20 July 2020, 14.00 PM)

Forms of verbal bullying that have been experienced by children are the behavior of mocking children at school and outside of school.

(KE, 38 Years, 29 July 2020, 14.00 PM)

According to the parents of the victim, the form of verbal bullying that has been experienced by the child is the behavior of being ridiculed by friends at school and

outside of school until the child gets ridicule treatment and even the child is called not his real name. In the FGD, the parents of the victims of the students expressed the same thing if their children often got ridiculed by calling them not their names, sometimes with the names of their parents which resulted in ridicule.

Based on the results of the interviews and the results of the FGD, it was found that the forms of verbal bullying that were carried out by the students varied, from making fun of, threatening and insulting the physical form of friends to the form of bullying that was often faced by victim students when the perpetrator's wishes were not fulfilled. This is due to the existence of peers who are one of the factors that influence verbal bullying at school. Peers are one of the biggest factors in someone engaging in verbal bullying. When a child has entered adolescence, he is no longer dependent on family, but tries to find support from his peers [16]. About 20-25% of teenagers are directly involved in bullying as perpetrators, victims, or both. Large-scale studies conducted in Western countries show 4-9% of adolescents frequently engage in bullying and 9-25% of school-age children in bullying.

The cause of verbal bullying in the form of direct contact is because it often annoys others by deliberately making fun of parents' nicknames and talking dirty to others. This finding is in line with the results of the study that direct verbal contact is part of the talk of violence directly to someone. For example spreading gossip, criticizing or teasing, cursing, giving nicknames, and so on [17]. Forms of verbal bullying behavior shown by the perpetrator to the victim can be in the form of mocking, insulting, and offensive remarks [18]. Storey has the view that verbal bullying includes mocking, yelling, making fun of and insulting [19]. Verbal bullying is a form of bullying behavior that can be captured through auditory envy. Forms of verbal bullying include: calling, yelling, scolding, insulting, humiliating in public, accusing, shouting, spreading gossip, and slandering .

Bullying behavior in schools is a pattern of negative behavior that is repeated and aims negatively. This behavior leads directly from one child to another because of an imbalance in power that aims to bully the weaker child. Bullying behavior in schools with the form of direct verbal contact, namely behavior that is in the form of talking directly to someone, forms of behavior that often occur such as talking dirty and mocking by carrying the name of the parents[20-28].

Conclusions and Suggestions

The results of the study concluded that the forms of verbal bullying that occurred varied, ranging from harassing, threatening friends, using harsh words, calling parents' names and nicknames which were made fun of. Therefore, schools should intensify the activities of the ambassador team so that verbal bullying can be minimized and teachers need to add insight into verbal bullying.

The Effect of Massage Therapy Method, Therapy Duration and Injuries on the Reduction of Pain in Knee Ijuries

Arif Setiawan[1], Soegiyanto[2], Tri Rustiadi[2], Rumini[2]

[1]Doctoral Student, Post Graduate Dept., Universitas Negeri Semarang, Indonesia,
[2]Lecture, Post Graduate Dept., Universitas Negeri Semarang, Indonesia

Abstract

The aim of the study was to explain the effect of effriction and frirage massage therapy, with a therapy duration of 10 minutes and 15 minutes in helping to reduce movement pain around the injured joint, the injured joint was the ACL ligament which was injured for 1 month and 2 months but pain in the surrounding muscles. ACL at the time of massage therapy was still felt by injured patients. This study was an experiment by providing 2 types of therapy, namely effriction and frirage therapy. Each therapy is a combination of two massage method to get maximum results in reducing pain during flexion and extension of the thigh muscles. With a factorial design with a sample size of 64 people with the criteria to be the sample, namely purposive sampling with injury for 1 month and 2 months. Physical assessment test instruments for pain with an analog visual scale are used to map changes and decreases in pain before treatment and after therapy and changes in range of motion in the knee to support the healing process assisted by these therapeutic method during the effriction massage therapy intervention. Subjective reporting on the level and function of pain is also documented. The results of the study for the homogeneity test mean that the data are homogeneous, and there is a significant difference between the 1 month and 2 month injuries. It was obtained that for massage therapy with an effriction treatment, the duration of the injury was 1 month with a duration of 10 minutes of therapy, which experienced a significant reduction in pain by 0.047 and for effriction therapy with a duration of 15 minutes, it had a significance of 0.049 so that for effriction therapy the duration of the injury was 1 month and for frirage therapy the duration of the injury was 1 month. months with 15 minutes of therapy in this group alone experienced a significant reduction. So that for 1 month there was no interaction between the independent variables and the dependent variable for the duration of 2 months there was an interaction because many factors influenced the reduction of pain and must be described in other studies. Effriction massage therapy is determined as a complementary therapy that is effective in helping to reduce pain relief in knee injuries, especially for 1 month injuries with a duration of 10 minutes and 15 minutes and frirage can significantly reduce pain in the injury duration of 1 month with a therapy duration of 15 minutes, and the type for this therapy there was a non-significant reduction in injury duration of 2 months.

Keywords: *Massage Therapy, Therapy Duration, Injuries, Reduction of Pain.*

Introduction

Sports activities and strenuous physical exercise with high intensity and tiring can cause problems for athletes and sportsmen. One of the problems that occurs is sports injuries, which result in not being able to train and do activities anymore[1]. Sports injuries are all kinds of injuries that arise, either during training or during a match or afterwards. An injury is a damage to the structure or function of the body due to force or physical pressure from outside or from within which causes pain resulting from an accident or sport. Based on the time the injury occurs, it can be classified into two, namely traumatic injury and overuse injuries. Traumatic injury is a serious injury that just happened suddenly such as dislocation, fracture, sprain, strain and can break the tendon. Whereas

Doctoral Student, Post Graduate Dept., Universitas Negeri Semarang, Indonesia
e-mail: aguspurwanto.prof@gmail.com

overuse injuries are caused due to repetitive movements that are too fast and a lot of movement, this overuse injury is often experienced by athletes, starting from the existence of a slightly excessive force repeatedly for a long time [2]. Indicators of injury are marked by the body with signs of inflammation such as: 1) heat (increased body temperature), 2) dolor (pain), 3) rubor (red skin), 4) tumor (swelling), and 5) function leissa (can no longer be used due to tissue damage to muscles, tendons, ligaments, joints, and bones due to excessive movement activity or accidents).[3]

Various kinds of efforts are made to deal with injuries, for example, medical actions that involve medical SOPs, supported by drugs, in addition to medical actions there are also non-medical actions that use various therapeutic method taking into account the level of injury suffered by sports injury sufferers. The therapeutic method used in this study is massage therapy method. Massage is derived from the Arabic word "mash" which means "to press gently" or the Greek word "massien" which means "to massage" or "to knead". Furthermore, massage is also known as massage science or lulut science. In providing massage treatment that aims to help the injury recovery process depends on the accuracy of handling the injury experienced. The factors that determine the accuracy of treatment are the type or method of therapy, the duration of treatment and the duration of the injury[3]. Massage not only knows the types, techniques and physiological benefits of massage that can be used to increase flexibility and performance but also massage is used for the process of muscle recovery and injury rehabilitation for sports injury sufferers. Therefore, it is necessary to strive for proper and fast handling so that sports injury sufferers can recover optimally so that sports injury sufferers can take part in every exercise or competition[4].

There are only a few techniques used to provide massage treatment to injuries. In general the techniques used are efflurage, friction, petrissage, tapotement, vibration techniques with a treatment duration of more than 15 minutes to reduce post-exercise pain[5].Whereas for injury recovery, the technique used is a combination of existing techniques, namely the Swedish massage technique on the grounds that when providing treatment at least 2 combined techniques, effriction and frirage techniques are selected with a duration of 10 minutes and 15 minutes on the grounds that they can provide time efficiency in treatment. and directly to the part directly related to the injury suffered.

The use of the effriction therapy method was chosen because this technique is a combination of efflurage and friction in the implementation of the treatment, there is massaging with the palm of the hand, there is a speed and massage pressure in the area of the quadriceps muscle and the surface hamstring muscles being treated. While the frirage therapy method is a combination of frikcion and efflurage, but the dominant treatment is pressing with the thumb and there is no excessive pressure or speed in massaging the surface of the treated area. The frirage therapy method is a combination of massage techniques or manipulations of friction and effleurage techniques which are carried out simultaneously in doing massage[4]. The hope of massage therapy which is carried out with the duration of treatment time so that sports injury sufferers do not return to the same injury in the near future[6].owever, there are other factors that influence, namely the duration of the injury and the type of injury.

The duration of the injury and the duration of the injury affect the recovery process, because injuries that do not heal quickly are caused by mishandling due to unprofessional handling or therapy in the case of injuries. The intended professionals are those who understand the development of the massage world and are competent in handling injuries, so that the duration of the injury must be known so that the treatment is not wrong. With the acute period passed and not yet treated by the therapist based on field data that the researcher did for one year in the research clinic, the injury usually lasted about 1 month. Whereas in the range of 2 months and above, the injury has usually been treated but has not changed and even there has been mishandling. Another factor that follows is the type of injury, Injuries are the most frequent namely injury to the knee joint. Injury to the knee joint involves damage to the anterior cruciate ligament (ACL) [6]. The number of athletes who are injured is 150,000 each year from male and female athletes in basketball and football. It is related to the injury to athletes who go to the Multispecialty Sports Clinic from 19 sports. There were 12,681 sports injury sufferers who suffered leg and ankle injuries. Due to the athlete's injury, the opportunity to participate in the championship is lost by 20% - 35%. Based on field data that the researchers conducted from January to December 2018 at the Sports Injury Massage Research Clinic, the total number of injuries was 1,506 from various injury variations. In one year there were 481 sports injury sufferers who suffered knee injuries, if the percentage of knee injuries in one year was 31, 93%.

The knee has the largest percentage of injuries, reaching 22.5% because it has multiple functions, namely as a driving and weight bearing, so that the possibility of injury is even greater. Therefore, it can be concluded that the most common injuries suffered by sports injury sufferers are knee injuries[7]. If someone has a knee injury, they will experience great pain. According to the International Association for the Study of Pain (IASP) pain is an unpleasant sensory and emotional experience due to damage or threat of damage to tissues Pain is the most common patient complaint and anxiety due to pain will serve as a warning to clinicians. Pain is a perceptual and sensual phenomenon and it is important for the body to be protected from injury so that humans can survive. Pain is very disturbing and troublesome for more people than any disease [8].

The high prevalence of pain proves that pain is still neglected. Management of lax pain has adverse consequences. This can cause pain in the muscles and interfere with movement activities, because the pain that is focused on in this discussion is pain due to sports injuries. Pain can also cause various psychosocial effects including depression, anxiety, delirium, post-traumatic stress disorder, and disorientation . Sports injury sufferers will feel pain need adequate therapy to relieve pain, because the pain not handled properly can aggravate the physical and mental condition of the sports injury sufferer. Any pain that arises will make the body respond to the painful stimuli, which in turn will affect the activity and organ systems of the sufferer. One of the ways to treat pain is massage therapy. Pain in the knee that often occurs includes injury to the anterior cruciate ligament (ACL) which is the most common knee injury in sports (Arovah, 2010) 8. Knee ligament injuries can cause sudden pain, swelling of the knee, a crackling sound from the injured knee, loose knee joints, and pain every time you lift weights. The recovery period depends on the severity of the injury and the treatment given. The characteristics of knee injuries are athletes feeling pain in the injured area, edema of the muscles or ligaments around the joints and decreased joint movement activity Research data carried out for one year in 2018 can be concluded that the subjects of this study were sports injury sufferers who had chronic knee injuries with injury duration of 1 month and 2 months who were given a combination of effriction and frirage massage therapy with a duration of time. 10 minutes and 15 minutes. As an indicator of using pain reduction in knee injuries9.

Based on the formulation of the problem that has been described above, the researcher will analyze several objectives as follows:

1. The effect of massage therapy method effriction duration of 10 minutes with injury duration of 1 month on pain reduction?
2. The effect of massage effriction therapy method with duration of 15 minutes with 1 month on pain reduction?Effect of massage therapy method effriction duration of 10 minutes with injury of 2 months on pain reduction?
3. The effect of massage therapy method effriction duration of 15 minutes with injury for 2 months on pain reduction?
4. The effect of frirage massage therapy method of duration of 10 minutes of injury to 1 month on pain reduction?
5. The effect of frirage massage therapy method with duration of 15 minutes of injury to 1 month on pain reduction?
6. The effect of the frirage massage therapy method, the duration of 10 minutes, the injury to 2 months, on the reduction of pain?
7. The effect of frirage massage therapy method with duration of 15 minutes injury 2 months on pain reduction?
8. How does the interaction between the 10 minutes effriction massage therapy method and the Frirage massage therapy for 10 injuries 1 month reduce pain?
9. How does the interaction of 15 minutes effriction massage therapy method with frirage massage therapy 15 for 1 month injury to reduce pain?
10. How does the interaction between the 10 minutes effriction massage therapy method and the Frirage massage therapy 10 minutes injury 2 months to reduce pain?
11. How does the interaction of 15 minutes effriction massage therapy method with frirage massage therapy 15 for 2 months injury to decrease pain?

Method

This study consists of three variables, namely the independent variable, the attribute variable and the dependent variable. There are 2 manipulated independent variables, namely: 1) effriction massage therapy

method, 2) frirage massage therapy, attribute variables are therapy duration and injury duration consisting of: 1) duration of therapy with 10 minutes and 15 minutes 2) duration of injury 1 month and 2 months. While the dependent variable is a decrease in pain. The relationship between independent and dependent variables in quasi-experimental research like this is called experimental design with factorials, namely the research structure that investigates three kinds of independent variables, whether each of these variables affects the dependent variable. Effriction massage therapy method and frirage massage therapy method, therapy duration of 10 and 15 minutes, and duration of injury 1 and 2 months. Meanwhile, the dependent variable is a decrease in pain. This study used a quasi-experimental method with a factorial design. Therefore, the design in this study is a factorial experimental design in block design because the experimental units in the relative block are homogeneous and the many experimental units in a block are the same as the many treatments being studied.

The population is limited as a number of residents or individuals who at least have one characteristic in common. In quantitative research, population is defined as an area of generalization consisting of objects or subjects that have certain quantities and characteristics determined by the researcher with the aim of obtaining and then drawing conclusions[9]. The population in this study amounted to 200. Of these who have the same characteristics, the characteristics of the population are as follows: 1) chronic knee injury, 2) male gender, 3) knee injury 1 and 2 months, 4) causes of injury from sports, and 5) age range 18-30 years. The sample is part of the number and characteristics of the population. The sampling technique uses proposive screening. This study is a sample study that only examines a part of the population. The sample used in this study were injury patients who had chronic knee injuries and those who were accompanied by pain total 40.

There are three variables in this study, namely the independent variable that is manipulated, the attribute variable and the dependent variable. To avoid differences in the interpretation of terms on the variables contained in this study, it is necessary to convey or put forward the operational definition as follows:

1. There are 2 manipulated independent variables, namely: 1) effriction massage therapy is a massage method with a combination of efflurage and friction manipulation that uses the entire palm and fingers, 2) frirage massage therapy is a combination of massage method with friction and efflurage manipulation using the thumb only.
2. The attribute variables were duration of therapy and duration of injury which consisted of: 1) duration of therapy with 10 minutes and 15 minutes 2) duration of injury 1 month and 2 months.
3. The dependent variable is decreased pain

Research instruments are tools or facilities used by researchers to collect data so that research implementation is easier and research results are better, in the sense that research is more careful, research is more complete and research is more systematic so that data processing is more accurate[10]. The instrument used was the VAS (visual analog scale) to measure pain. The data collected in this study were data on the results of the effriction massage therapy method with a therapy duration of 10 and 15 minutes and an injury duration of 1 and 2 months, the frirage massage therapy method with a therapy duration of 10 and 15 minutes and an injury duration of 1 and 2 months on the measurement of pain in the injury. knee that can be generalized or applied to other samples in the population studied, it is necessary to talk about various things that can affect the results of yaotu's research: in the presence of: 1) internal validity and 2) external validity [11].nternal validity relating to the validity of the conclusions drawn about the cause and effect of the relationship between the independent and dependent variables. Meanwhile, external validity, which refers to the validity of the cause – effect relationship generalized to others, the setting, the validity to solve problems, and further action[11].

In this study, the following requirements were tested: Normality test with Kolmogorov Smirnov. The data found were VAS measurement data, the Kolmogorov Smirnov normality test was performed ($p > 0.05$) and the results were normally distributed data.Homogenitis Test,the data found were VAS measurement data on the quad dricep muscle and hamstring muscle. The homogeneity test was performed using the Levene test ($p > 0.05$) and the results were homogeneous data variants. ANOVA test and LSD test, ANOVA test ($p < 0.05$) to determine whether there is an effect of massage therapy treatment effriction, effleurage on reducing pain in knee injuries. After the research data was collected, the data was processed using the parametric ANOVA test at a significance level of 0.5%, through the SPSS program[12].

Internal validity shows that the test differences on the dependent variable are the result of manipulation of each independent variable that is different in each group, while external validity is where the results can be generalized or applied to groups and environments that are not experimental treatment, in this study the validity of the design. internal, among others: 1) The effect of the physical condition of the sample who suffered an injury, namely not experiencing pain other than the injury suffered, 2) The effect of physical maturity, is to select a sample of the same gender from a similar age range, so that it is expected to have the same characteristics, in the sense that it has the same maturity, 3) The effect of time, the time of research is controlled in such a way as to avoid the existence of various forms of intervention that make injuries the higher the level of injury suffered by the sample, 4) The effect of natural conditions, is to adjust the serving time, 5) Slow Treatment for each group so that the conditions are at the same level, but the time is arranged in such a way that there is no significant difference, the treatment is carried out with the intervention of the type of massage, duration of injury and duration of therapy, 6) Effect of tests, control of the test by giving time the same breaks at the final data collection, no experimental treatment at the time of performing the test[13].

The results of this experiment were generalized from the population, the sampling in this study was carried out purposively, carried out by considering that the subjects had gone through screening, with the level of injury being adjusted to the level of injury taken and the level of stress that was equal, so that it was considered to be of a similar level to be sampled in the experiment. this. Sampling is done by providing a pain test to determine the level of injury suffered. The pain test used is a visual analog scale or a numeric rating scale to determine the group in Control of Ecological Validity[14].

The ecological validity in this study are:

1. All treatments given must be predicted so that the implementation of this experiment can be generalized and used in another time.
2. The main relation, interaction relation and combination relation which is manipulated with the treatment effect can still be used at the same time, so that the treatment in this experiment. Sensitivity to the initial test is controlled in such a way as not to treat the initial test.
3. Trial of the implementation of teaching method and assessment of instruments carefully, so that the implementation of research for each group and the results of the assessment can be controlled properly.
4. Sensitivity to the test is controlled by not giving treatment to the implementation of the test.
5. Control of the dependent variable measurement, by controlling the test
6. Psychological influence in the implementation of experimental treatment

Result and Discussion

Data Description: The data that will be described by the researcher are data obtained from the field in the form of injury duration, therapy duration and pain reduction. The sample in this study amounted to 64 people who were divided into 8 groups. Data described in the form of injury duration were obtained from interviews with patients, meaning that the duration of the injury was from the time of incident to the arrival of clinical therapy for sports injury massage. Furthermore, decreased pain perception experienced by patients during therapy and post therapy.[15]

Duration of Therapy and Injury: The duration of injury experienced by athletes who suffered an injury in this study was grouped into 2 groups, in general, the duration of the injury was 1 month and the duration of the injury was 2 months. The therapy used was Effriction massage therapy, the duration of therapy was 10 minutes and 15 minutes of treatment and the sample requirements were injury for 1 month and injury for 2 months, with a sample of 64 people who were selected according to the verification sheet. From the raw data obtained, it can be described as follows:

Table 1: Descriptive Statistics based on mean and standard deviation

Descriptive Statistics					
Dependent Variable: PN					
J_T	**Durasicedera**	**Durasi Terapi**	**Mean**	**Std. Deviation**	**N**
Effriction	1month	10 minutes	6,0000	1,41421	8
		15minutes	4,8750	,35355	8

		15minutes	4,5000	,73030	16
		Total	5,0625	1,21649	32
	2month	10 minutes	3,9375	2,14379	16
		15minutes	3,8750	1,31022	16
		Total	3,9063	1,74798	32
	Total	10 minutes	4,7813	1,96312	32
		15minutes	4,1875	1,09065	32
		Total	4,4844	1,60349	64

The calculation of the normality test is carried out with the aim of knowing whether the research data is normally distributed or not. The results of data normality calculations obtained with a value of p> 0.05, the data is normally distributed. All test indicators are sig values 0.282 ≥ 5%, so Ho is accepted, thus the research data is homogeneous.

Effect of Effriction Therapy with 10 Minutes of Therapy Duration with 1 Month of Injury on Pain: Data analysis was performed to examine the effect of type of therapy, duration of therapy and duration of injury on reduction of pain levels in patients with knee injuries. In this section, the type of therapy used is effriction therapy with a therapy duration of 10 minutes and an injury duration of 1 month with a selected sample of 8 people. Statistical analysis shows that the t test results above show that the significance is 0.047. The test results are known to be smaller than 0.05 (0.047 <0.05) so that the hypothesis is accepted, meaning that there is a significant effect of massage effriction therapy with a

therapy duration of 10 minutes and an injury duration of 1 month on pain perception in knee injuries.

Effect of Effriction Therapy with a Therapy Duration of 15 Minutes and an Injury Duration of 1 Month on Pain: Data analysis was performed to examine the effect of type of therapy, duration of therapy and duration of injury on reduction of pain levels in patients with knee injuries. In this section, the type of therapy used is effriction therapy with a therapy duration of 15 minutes and an injury duration of 1 month with a selected sample of 8 people. Statistical analysis shows that the t test results above show that the significance is 0.049. The test results are known to be smaller than 0.05 (0.047 <0.05) so that the hypothesis is accepted, meaning that there is a significant effect of massage effriction therapy with a therapy duration of 15 minutes and an injury duration of 1 month on pain perception in knee injuries.

Effect of Effriction Therapy with a Therapy Duration of 10 Minutes and an Injury Duration of 2 Months on Pain: Data analysis was performed to examine the effect of type of therapy, duration of therapy and duration of injury on reduction of pain levels in patients with knee injuries. In this section, the type of therapy used is effriction therapy with a therapy duration of 10 minutes and an injury duration of 2 months with a selected sample of 8 people, statistical analysis obtained 0.056. The test result is known to be greater than 0.05 (0.056> 0.05) so that the hypothesis is rejected, meaning that there is no significant effect of massage effriction therapy, 10 minutes duration and 2 months of injury duration on reducing pain in knee injuries.

Effect of Effriction Therapy with a duration of 15 minutes of therapy with an injury duration of 2 months on pain: Data analysis was performed to examine the effect of type of therapy, duration of therapy and duration of injury on reduction of pain levels in patients with knee injuries. In this section, the type of therapy used is effriction therapy with a therapy duration of 15 minutes and an injury duration of 2 months with a selected sample of 8 people. Statistical analysis shows that the t test results above show that the significance is 0.063. The test results are known to be greater than 0.05 (0.063> 0.05) so that the hypothesis is rejected, meaning that there is no significant effect of massage effriction therapy, 15 minutes duration and 2 months of injury duration on reducing pain in knee injuries.

Effect of frirage therapy with a therapy duration of 10 minutes and an injury duration of 1 month on pain: Data analysis was performed to examine the effect of type of therapy, duration of therapy and duration of injury on reduction of pain levels in patients with knee injuries. In this section, the type of therapy used is Frirage therapy with a therapy duration of 10 minutes and an injury duration of 1 month with a selected sample of 8 people. Statistical analysis showed that the t test results above showed that the significance was obtained 0.061. The test result is known to be greater than 0.061 (0.061> 0.05) so that the hypothesis is rejected, meaning that there is no significant effect of frirage massage therapy, 10 minutes duration and 1 month injury duration on reducing pain in knee injuries.

Effect of frirage therapy with a therapy duration of 15 minutes with an injury duration of 1 month on pain: Data analysis was performed to examine the effect of type of therapy, duration of therapy and duration of injury on reduction of pain levels in patients with knee injuries. In this section, the type of therapy used is Frirage therapy with a therapy duration of 10 minutes and an injury duration of 1 month with a selected sample of 8 people. Statistical analysis shows that the t test results above show that the significance is 0.050. The test result is known to be greater than 0.050 (0.061> 0.05) so that the hypothesis is accepted, meaning that there is a significant effect of frirage massage therapy, 15 minutes duration and 1 month injury duration on reducing pain in knee injuries.

Effect of frirage therapy with a therapy duration of 10 minutes with a duration of injury of 2 months on pain: Data analysis was performed to examine the effect of type of therapy, duration of therapy and duration of injury on reduction of pain levels in patients with knee injuries. In this section, the type of therapy used is Frirage therapy with a therapy duration of 10 minutes and an injury duration of 2 months with a selected sample of 8 people. Statistical analysis showed that the t test results above showed that the significance was obtained 0.063. The test results are known to be greater than 0.063 (0.063> 0.05) so that the hypothesis is rejected, meaning that there is no significant effect of frirage massage therapy, 10 minutes duration and 2 months of injury duration on reducing pain in knee injuries.

Effect of frirage therapy with a therapy duration of 15 minutes with a duration of injury of 2 months

on pain: Data analysis was performed to examine the effect of type of therapy, duration of therapy and duration of injury on reduction of pain levels in patients with knee injuries. In this section, the type of therapy used is Frirage therapy with a therapy duration of 15 minutes and an injury duration of 2 months with a selected sample of 8 people. Statistical analysis showed that the results of the t test above showed that the significance was obtained 0.063. The test results are known to be greater than 0.063 (0.063> 0.05) so that the hypothesis is rejected, meaning that there is no significant effect of frirage massage therapy, 15 minutes of therapy duration and 2 months of injury duration on reducing pain in knee injuries. Significance values that appear are important values and it can be concluded that the effect of all independent variables on the type of massage, duration of therapy and duration of injury on pain reduction. The duration of therapy simultaneously affects the dependent variable (pain reduction). If Significance (Sig.) <0.05 (Alfa) = Significant. Based on the table. The significance (Sig.) Of the Corrected Model shows 0,000 means that the model is valid. The value of changes in the dependent variable without the need to be influenced by the existence of an independent variable, meaning that without the influence of the independent variable, the dependent variable can change in value. If Significance (Sig.) <0.05 (Alfa) = Significant. Based on the Significance Table (Sig.) Of the Intercept, it shows 0.000, which means that the Intercept is significant. The error value of the model, the smaller the model the better. The value of multiple determination of all independent variables with the dependent. R Squared shows 0.553 which is close to 1, meaning strong influence.

Conclusion

The results of the study for the homogeneity test mean that the data are homogeneous, and there is a significant difference between 1 month and 2 months of injury. It was obtained that for massage therapy with an effriction treatment, the duration of the injury was 1 month with a duration of 10 minutes of therapy, which experienced a significant reduction in pain by 0.047 and for effriction therapy with a duration of 15 minutes, it had a significance of 0.049 so that for effriction therapy the duration of the injury was 1 month and for frirage therapy the duration of the injury was 1 month. months with 15 minutes of therapy in this group alone experienced a significant reduction. So that for 1 month there was no interaction between the independent variables and the dependent variable for the duration of 2 months there was an interaction because many factors influenced the reduction of pain and must be described in other studies. Effriction massage therapy is determined as a complementary therapy that is effective in helping to reduce pain relief in knee injuries, especially for 1 month injuries with a duration of 10 minutes and 15 minutes and frirage can significantly reduce pain in the injury duration of 1 month with a therapy duration of 15 minutes, and the type for this therapy there was a non-significant reduction in injury duration of 2 months.

Familial Phenotype of Waardenburg Syndrome in One Family: A Case Series

Eka Savitri[1], Indra Irawan[1], Habibah S. Muhiddin[1], Fadly[1]

[1]*Lecturers of Department of Otorhinolaryngology, Faculty of Medicine Universitashasanuddin, Makassar*

Abstract

Waardenburg syndromeis an accumulation of some genetic conditions which leads to sensorineural hearing loss (SNHL) and depigmentation of hair, skin, and eyes. The cause of sensorineural hearing loss in children can be congenital or hereditary, characterized by sensorineural deafness, associated with pigment disorders and tissue defects. Based on the accompanying symptoms, Waardenburg syndrome is divided into 4 types, where the most often ones are type 1 and 2. Clinical symptoms including dystopia canthorum, pigment disorders (white crest, abnormalities of eyebrow, eyelashes, body hair and iris heterochromia), sensorineural deafness, protruding nose and depigmentedhair at young age. Based on physical and additional examinations performed on five patients, all results showed mayor and minor symptoms of waardenberg syndrome accompanied by dystopia canthorum, therefore classified aswaardenburg type 1.

Conclusion: All patients are classified as type 1 Waandenberg syndrome which were inherited in the form of autosomal dominant.

Keywords: *SNHL, Waardenburg syndrome, dystopia canthorum, autosomal dominant.*

Introduction

Deafness is one of the problems in children that will affect speech, social, cognitive and academic development. Deafness can be caused by congenital or acquired abnormalities.(1) In developed countries, the rate of congenital deafness ranges from 0.1 to 0.3% of live births, whereas the number in Indonesia is about 0.1% based on a survey conducted by the health department in 7 provinces from 1994 to 1996. Congenital deafness in Indonesia is estimated to be around 214,100, considering the number of total population is 214,100,000 million. This number will increase every year with an increase in population due to the high birth rate, 0.22% from the previous one.(2) Congenital deafness occurs in a baby due to factors that affect pregnancy and delivery processes. Congenital deafness can be genetic (hereditary) and non genetic. Non genetic congenital deafness is determined by the mother's condition during pregnancy and delivery processes.(3)

Waardenburg syndrome is one of congenital hereditary deafness, firstly discovered by an ophthalmologist from the Netherlands named Petrus Johannes Waardenburg in 1947. He initially found some symptoms of canthorum dystopia, different eye pigment colors (heterochromia) and deafness.(1,4) In 1951, after identifying other patients with the same symptoms, Waardenburg classified patients with these symptoms into Waardenburg type I syndrome. In 1971, Arias further defined Waardenburg type II syndrome.(5) Then in 1981, Shah and other researchers discovered infants with Hirschprung's disease and white forelock which is classified as Waardenburg type IV syndrome. Then in 1983, Klein discovered patients with type I symptoms accompanied by abnormalities of arm hypoplasia and arthrogyposis on the hands and wrists, which were then classified as Waardenburg type III syndrome.(6)

Waardenburg syndrome is an accumulation of some genetic conditions which leads to sensorineural hearing loss (SNHL) and depigmentation of hair, skin, and eyes.

Although most people with Waardenburg syndrome have normal hearing, waardenburg syndrome can also cause moderate to very severe hearing loss which can occur in one or both ears and can occur from birth. Someone with this condition often has very pale blue eyes or even different eye color one to another,in some cases one eye is blue while the opposite eye is brown. Sometimes one eye even has two different colors. Typical hair coloring such as white hair or hair that turns into premature gray is another common sign of waardenburg syndrome.[7,8]

The most common characteristic of waardenburg syndrome is iris color differentiation between the two eyes: one eye usually has brown iris and the opposite eye is blue. Sometimes color differences are found in one eye, or in some cases both eyes are bright blue. Since deafness often arises as a symptom of this syndrome, hearing examination and treatment, such as the use of hearing aids and the selection of schools suitable for child development, should be a concern.[7,8]

Case Report: An examination was conducted on a family with some family members who had a lineage of waardenburg syndrome where the phenotype of waardenburg syndrome was present in the last 3 generation.There were no recorded inbreeding in the family and there were no marriages of family members with other people known to suffer from waardenburg syndrome.

Case 1: A 16-year-old girl (Ms.F) is suspected of having hearing loss since she was a baby,for she did not respond when called and could not speak at all. Her eyes are blue since birth, and there were family members having the same abnormalities which were her sister and aparents. No abnormalities were found in the prenatal, perinatal and postnatal history. Motor developments were good according to her age.

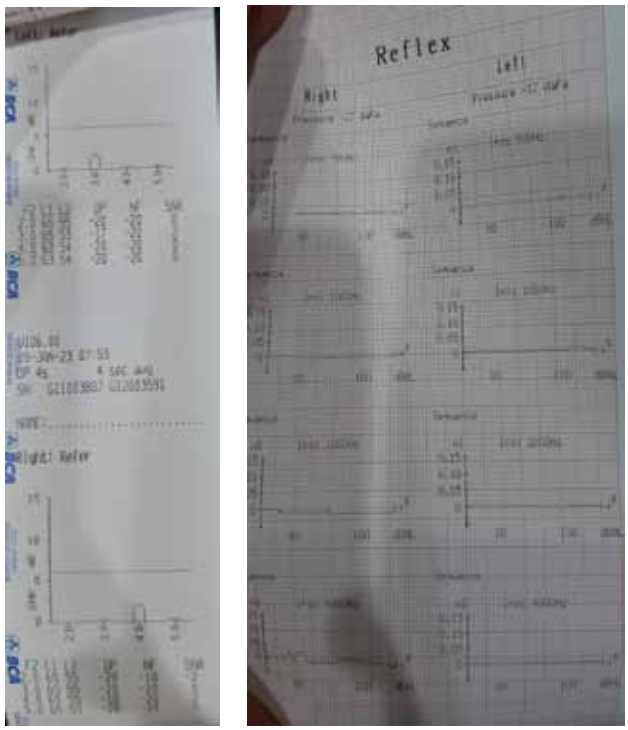
Physical examination of the ear, nose, oropharynx and neck revealed no abnormalities, while the examination on maxillofacial region showed abnormalities of iris pigments in the form of complete iris heterochromia, canthorumdystopia, and alanasi hypoplasia. Musculoskeletal and gastrointestinal were normal.

Audiological examination revealed total deaf audiogram, with type A/type Atympanogram, and no acoustic reflexes in both ears. OAE examination referred to both ears, concluded as abnormality in left/right outer cochlear hair cells.

Case 2: A 38-year-old woman (Mrs. H) was suspected of having hearing loss since she was a baby, for she did not respond when called and could not speak at all. Her eyes are blue since birth, and there was a history of hair pigment changes (whitening) before the age of 30, along with familial history of the same abnormality. Her son also has blue eyesyet without any hearing loss.

Examination of the ear, nose, oropharynx and neck showed no abnormalities, whereas examination of the maxillofacial region showed irregular pigment abnormalities in the form of complete heterocromia of the iris, canthorumdystopia (W index>1.95), premature gray hair and broad nasal root. Musculoskeletal and gastrointestinal tract are within normal limits.

The result of the audiology examination showed total deafness,with type A/type A tympanogram, and no acoustic reflexes in both ears. OAE examination showed refer to both ears, concluded as abnormality in left/right outer cochlear hair cells.



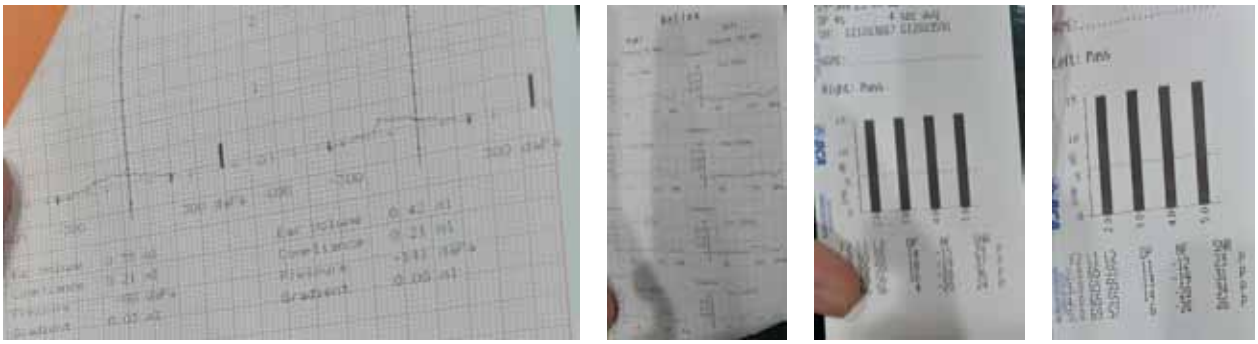
Picture 1. The result of OAE and reflexes examination in Mrs.H

Case 3: A boy (M) aged 1 year 10 months has unilateral blue eye from birth, with no abnormalities in the prenatal, perinatal and postnatal periods. His mother does not have a history of serious illness during pregnancy. The patient is a child of a mother suffering

from type 1 waardenberg syndrome and a father who is deaf. There is no history of seizures.

Physical examination of the ear, nose, oropharynx and neck did not show any abnormalities, while examination of the maxillofacial region showed pigment abnormalities in the form of partial heterochromia, dystopia canthorum, synophyrys and alanasihypoplasia. Musculoskeletal and gastrointestinal tract are within normal limits.

The result of the tympanometry examination are type A/type Atympanogram, and the acoustic reflexes in both ears are within normal limits. OAE examination revealed a pass in both ears, so it was concluded that there was no disruption of the right/left outer cochlear hair cells.

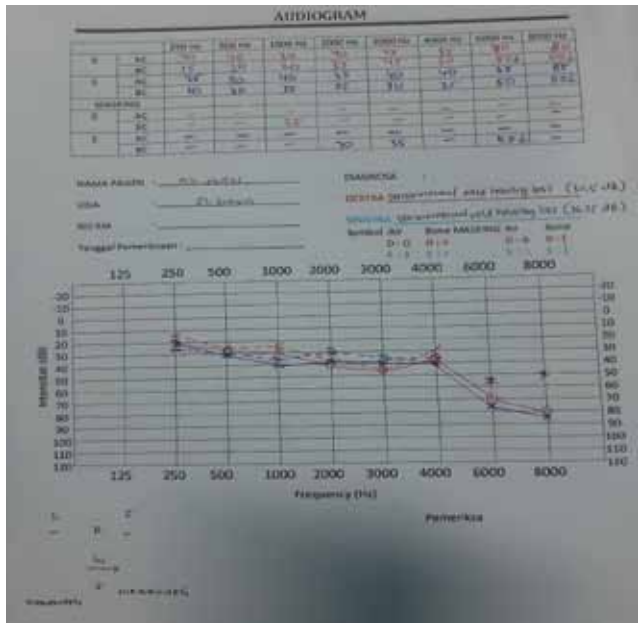


Picture 2. The result of tympanometry and OAE in boy M

Picture 3. Heterochromia in Mrs.M

Case 4: A 52-year-old woman (Mrs. M) has blue eyes since birth, and there is a history of changes in hair pigment (whitening) before the age of 30. There is a family history of the same abnormality. The patient has a boy who has blue eyes yet without hearing loss.

Examination of the ear, nose, oropharynx and neck showed no abnormalities, whereas examination of the maxillofacial region showed pigment abnormalities in the form of complete heterocromia of the iris, canthorumdystopia (W index>1.95), premature gray hair and broad nasal root. Musculoskeletal and gastrointestinal tract are within normal limits. Audiometry examination showed mild sensorineural hearing loss.



Picture 4. The result of audiometry in Mrs. M

Case 5: A 45-year-old woman (Mrs. R) has a history of changes in hair pigment (turning white) before the age of 30, without blue eyes. There is a family history of the same disorder. The patient had a boy who had blue eyes

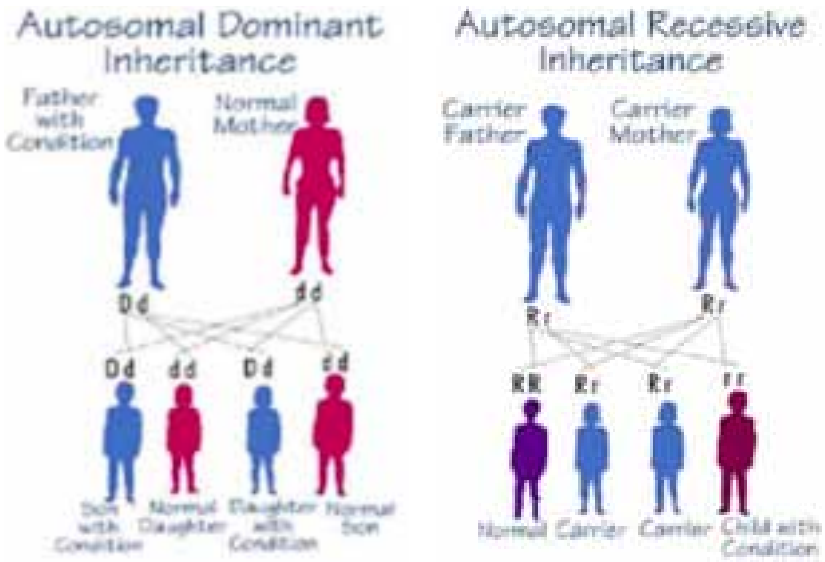
without hearing loss, and one girl who had blue eyes accompanied by severe sensorineural hearing loss from birth.

Picture 5. Heterochromia in Mrs.F

Examination of the ear, nose, oropharynx and neck showed no abnormalities, whereas examination of the maxillofacial region showed pigment abnormalities in the form of complete heterocromia of the iris, canthorumdystopia (W index>1.95), premature gray hair and broad nasal root. Musculoskeletal and gastrointestinal tract are within normal limits. Audiometry examination showed moderate sensorineural hearing loss.

Waardenburg syndrome is an autosomal dominant inherited disorder with the most frequent manifestations of congenital sensorineural deafness and disorders of hair and skin pigmentation.[1,2]

Waardenburg syndrome types 1, 2 and 3 are inherited autosomal dominant, whereas type 4 is inherited autosomal recessive.[8]



Picture 6. The flow of inherited dominant and recessive autosomal[13]

Waadenburg type 1 is characterized by the presence of non-progressive congenital sensorineural deafness, dystopia canthorum, white forelock, and several minor abnormalities such as congenital leukoderma. Waardenburg type 2 and type 3 are characterized by the presence of dystopia canthorum and musculoskeletal abnormalities in the upper extremities (aplasia of the ribs, carpal bone abnormalities, cystic formation of sacrum bones, amyoplasia, joint stiffness and bilateral syndactyly). Furthermore, Waardenburg type 4 syndrome is characterized by iris heterochromia, sensorineural hearing loss and is accompanied by Hirschprung's disease.[3,4]

Table 1. Classification of clinical manifestation in Waardenburg syndrome[13]

Type	Clinical manifestation
I	Dystopia canthorum W > 1.95
II	No dystopia
III (Klein waardenburg)	Hypoplasia of extremity muscles such as elbow and fingers
IV (Shah- waadenburg)	Hirschsprung's disease

Waardenburg syndrome is an auditory-pigmentary disorder with a basic cause of hearing loss is the need for melanocytes in the cystic vascular cyst of the unexplained, for example in the case of albinism where hearing remains normal, but there is no melanocytes that cause the vascular stria to become thin, there is no growth of endocochlear, and the development of Reissner membrane is collapsed which leads to the damage of the organ of Corti. All melanocytes, except for the retina, originate from embryonic neural crest. The absence of melanocytes can be caused by failure of differentiation in the neural crest, failure of melanoblast to migrate, or failure of late differentiation or persist in the end place of melanoblast which can be caused by mutations in the genes that regulate it (PAX3, MITF, SOX10, and EDNRB).[11]

The Waardenburg Consortium in 1992 established diagnostic criteria for Waardenburg type 1 syndrome, where patients must have at least 2 major symptoms or 1 major symptom with 2 minor symptoms. Major symptoms include congenital sensorineural hearing loss; iris pigment disorders that can be in the form of complete heterochromic iris (both eyes are of different color), partial or segmental heterochromia (there are pigmented blue or brown segments in one eye or both eyes), hypoplastic blue eyes (bright blue eyes in both eyes), hair hypopigmentation in the form of white forelock, dystopia canthorum (w index> 1.95), with abnormalities also found in siblings. Furthermore, minor symptoms include congenital leukoderma (hypopigmentation areas can be found in several places), synophyrys (thick eyebrows that meet medially); wide or high nasal base; hypoplasia of alanasi, premature graying hair (especially scalp hair, before the age of 30 years). On the other hand, symptoms for type 2 Waardenburg syndrome by Lui et al include the presence of 2 major symptoms, with the exception of dystopia canthorum and including premature graying.[1,2,4]

Table 2. Diagnostic criteria of Waardenberg syndrome[12]

Major criteria	Minor criteria
• Congenital sensorineural hearing loss • White forelock, hair hypopigmentation • Pigmentation abnormality of the iris – Complete heterochromiairidum (irides of different color) – Partial/segmental heterochromia (two different colors in same iris, typically brown and blue) – Hypoplastic blue irides, or brilliant blue irides • Dystopia canthorum, W index >1.95 • Affected first-degree relative	• Skin hypopigmentation (congenital leukoderma) • Synophyrys/medial eyebrow flare • Broad/high nasal root, prominent columella • Hypoplasticalaenasi • Premature gray hair (before age 30 years)

Clinical abnormalities in Waardenburg type 1 can vary even if found in one family. The most common abnormality is sensorineural deafness which is congenital, unilateral or bilateral, and not progressive, with a very severe degree (>100 dB). In the eyes can also be found differences in color, generally one eye is blue and one eye is brown.[12,13]

Dystopia canthorum is determined from the W Index calculated based on the distance between the medial canthus (a), lateral canthus (c), and the distance between pupils (b) in millimeters, with the following formula. The diagnosis is established if the W index is more than 1.95.[3]

Congenital sensorineural deafness is a manifestation that often accompanies Waardenburg syndrome. Therefore, audiology examination has a very important role. Audiology screening can be performed on infants and children whose parents or families have a history of Waardenburg syndrome, although there are no clinical manifestations.

Congenital deafness causes problems with individual and social development of individuals. The use of hearing aids is one of the options that can be used as early as possible, to prevent the development of speech, language, mental, and intellectual development, so that patients are expected to live a normal life.

There are 2 method recommended for use in the examination of hearing loss in newborns, namely Otoacoustic Emission (OAE) and Auditory Brainstem Responses (ABR)/Brainstem Evoked Response Audiometry (BERA), which is usually done in a hospital in a state of calm sleep babies. Both are fast and easy to do, not invasive, inexpensive, and quite sensitive in detecting hearing loss.[10]

In the first case, the patient was diagnosed as type 1 waardenburg syndrome because of the bluish iris color and very severe neural sensory deafness, accompanied by dystopia canthorum. Furthermore, patient in the second case was also diagnosed as waardenburg type 1 syndrome due to bluish iris color and severe sensorineural deafness, and accompanied by dystopia canthorum. For the third case, the patient was diagnosed as waardenberg type 1 syndrome because of a unilateral grayish iris color without hearing loss, accompanied by dystopia canthorum.

In the fourth case, the patient was diagnosed as waardenburg type 1 syndrome due to a bluish iris color and moderate degree of sensorineural deafness, accompanied by dystopia canthorum. Subsequently, the fifth case was diagnosed as waardenberg type 1 syndrome due to unilateral gray iris color without hearing loss, accompanied by dystopia canthorum. All patients examined did not show any musculoskeletal and gastrointestinal abnormalities.

Management in patients with Waardenburg syndrome should be done as early as possible by using hearing aids (ABD) and auditory verbal therapy (AVT). In reported cases, treatment is aimed at deafness and correcting anatomical abnormalities through surgical procedures.

Deafness must be detected immediately and get treatment as early as possible. Genetic counseling can be done and attention is directed towards providing information about clinical manifestations that will emerge and the likelihood that a child will suffer from this syndrome from parents who have suffered from Waardenburg syndrome, so that disorders that must be treated immediately can be of concern to parents and family.[7,9]

Consultation with a geneticist is important, because people with type 1 and 2 Waanderburg generally have a 50% risk to inherit the syndrome to their baby during pregnancy. Consultation and examination by an ophthalmologist is needed to evaluate the visual and visual field and other abnormalities in the eye field. In general, people with Waardenburg syndrome have vision within normal limits. A dermatologist's consultation is done if there are abnormalities in the skin to rule out other diseases or malignancies. Evaluations by pediatricians are carried out for growth and development examinations, while surgeon evaluations are performed if there are abnormalities in other organs such as hirschprung's disease.[1,5]

Congenital deafness causes problems of individual and social development. Early detection and treatment offers hope in individual development. The use of hearing aids is one of the options that needs to be given as early as possible to prevent impaired speech, language, mental and intellectual development so that patients are expected to be able to live a normal life.[10]

In the field of otorhinolaryngology, the management of Waardenburg syndrome is aimed at hearing screening, evaluation of sensorineural deafness for hearing instrumentation, and when possible using cochlear implants. Other treatment is speech therapy so that people with Waardenburg syndrome can communicate.[15]

Early diagnosis and improvement of hearing defects are important for the psychological development of children with this congenital abnormality and also to help reduce feelings of isolation.[2] Management of hearing loss depends on the severity of the hearing loss. Cochlear implants are still the main choice for rehabilitation of hearing function in children with severe to severe sensorineural hearing loss. In patients with Waardenburg syndrome, the normal level of intelligence is normal and the hearing loss that occurs is sensoryneural, so that the use of cochlear implants can provide good results if accompanied by an intensive rehabilitation program.[14] The process of hearing rehabilitation in sensoryneural hearing loss provides a good prognosis, so that the implant kolkea is recommended for people with Waardenburg syndrome if there are no anatomical abnormalities in the inner ear, including cochlear hypoplasia, internal acoustic canal, absence of posterior semicircular canals and malformations in the other two semicircular canals.[14] Cochlear implants provide direct stimulation to the cochlear nerve fibers. Cochlear implants are indicated in both adults and children with very severe hearing loss who do not benefit from the use of conventional hearing aids. Prognosis of hearing, language development and sociability in young

children (deafness) is not only dependent on the optimal amplification of hearing aids or cochlear implants, but also depends on the type of rehabilitation education that the patient receives. There are various types of education that can be used as a rehabilitation process for patients with hearing loss. In education based on auditory-verbal communication, patients learn to use sound instructions optimally by practicing understanding languages and pronouncing language correctly. In oral communication, patients learn to hear and speak with the help of lip readings. In the type of total communication rehabilitation, a combination of oral language and sign language is taught to maximize communication skills.[14]

Management of hearing loss includes prevention, education, and psychological assessment. Prevention is done by avoiding predisposing factors such as marriage between sufferers of congenital deafness and marriage between families. Screening should start as early as possible, ideally all children aged 6-9 months have a definite hearing function, and then immediately after entering school at the age of 5-6 years. Very important at the educational stage is the rehabilitation of early training in deaf children, namely by using hearing aids (ABD) to utilize the remaining hearing function. Installation of ABD devices in children with severe or very severe deafness must begin as early as possible. This is done so that the development of speech and education is not too late. Cochlear implant considerations as indicated. In addition, speech therapy is also needed to correct speech disorders caused by congenital deafness. Home training includes early training that depends on the sufferer's parents. If it can be detected and treated early and well, then people with Waardenburg can live normally in the community.[15]

Family counseling is a very important component, because in case 2 it can be seen that the sufferer is married to a fellow deaf, and there is a family history of Waardenburg syndrome. If the patient is still planning to have a child, then an explanation is given that there is a tendency for his child to suffer from Waardenburg syndrome. After the child is born, hearing screening must be done as a first step. In the third case, the sufferer lives with his mother and father who are also deaf and speech impaired, so that both of them need counseling that their children need word learning by involving other family members who are not hearing impaired and talk impaired, or can also with the help of informatics media.[15]

Conclusion

Waardenburg syndrome is an autosomal dominant inherited disorder, with the most frequent manifestations of congenital sensorineural deafness and disorders of hair and skin pigmentation. Waardenburg syndrome is classified into 4 types, namely Waardenburg syndrome type 1, type 2, Klein-Waardenburg or type 3, and Waardenburg-Shah or type 4. Genetic mutations are suspected as a cause of Waardenburg syndrome. Interactions between the PAX3, MITF, SNAIL2 and SOX10 genes cause manifestations of deafness and pigmentation disorders. The five patients who were reported as belonging to type 1 waardenburg syndrome, based on the phenotype of each patient who was inherited autosomal dominant. Treatment is aimed at deafness and repairing anatomic abnormalities through surgery. Deafness must be detected immediately and get treatment as early as possible. Genetic counseling can be done, and attention is paid to providing information about clinical manifestations that will emerge and the possibility of a child suffering from this syndrome from parents who have suffered from Waardenburg syndrome, so that disorders that must be treated immediately can be of concern to parents and family.

Test Instrument Model Talk Athletes for Martial Branch Sports of Tarung Derajat

Ipang Setiawan[1], Soegiyanto[2], Mugiyo Hartono[2], Tri Rustiadi[2]

[1]Doctoral Student, Post Graduate Dept., Universitas Negeri Semarang, Indonesia,
[2]Lecture, Post Graduate Dept., Universitas Negeri Semarang, Indonesia

Abstract

The general pycological perspective that has been applied occurs after the formation of a good physical condition will be balanced with mental formation, in research and in this level of Traung Derajat, a psychological perspective will be developed at the beginning in finding athletes' talents with indicators that are determined according to the characteristics of the sparring sport, so that the series conducted is a process of identifying potential athletes to identify talented athletes who have the best abilities according to the character of the degree fighting sport. Based on the results of discussions with several expert qualifiers, the criteria in accordance with the character of the degree fighting sport are achievement, competitive, managing pressure, self-efficacy, fear failure control, stress management, emotion, empathy, power, aggressiveness, the results of the psychological test are converted in percentage to fall into the category of very potential, potential, sufficient potential, less potential, not potential. Norms in category making are taken from athletes from Central Java province with the highest achievement at the national level who win at PON which is the highest level followed by degree Traung Derajat. The method used is to modify the SPQ20 psychological test to be simple but not eliminate the main criteria in the test as agreed by the expert. The research sample used was athletes who were in the Semarang City regional task force with total sampling technique in order to get a picture of the potential of the athletes. The results of the study obtained data, namely the achievement component of 68%, competitive 66%, managing pressure 62.9%, self-efficacy 67, 78%, 63.73% fear failure control, 63.83% stress management, 65.56% emotion, 70.33% empathy, 54.40% power, 67.73% aggressiveness. Athletes in Satlak have the potential as Talented athlete candidates are 50 athletes or 64% from a psychological perspective. Based on the psychological perspective of the degree fighting athletes who will participate in potential training with an emphaty character of 70%, the other components will follow the development with physical and technical criteria.

Keyword: *Psychological perspective, potential athlete, Tarung Derajat.*

Introduction

Performance sports are one of the pillars of sports development as regulated in the Sports System Law. Achievement sports are sports that foster and develop sports in a planned, tiered, and sustainable manner through competitions to achieve achievement with the support of sports science and technology[1].

Sport talent identification is an effort that is carried out systematically to identify someone who has the potential in sports, so that it is estimated that someone will be successful in training and can reach peak performance. The process of identifying gifted athletes should be of concern to each sport, because the main objective of conducting talent scouting is to identify and select potential athletes who have the highest abilities in a particular sport[2]. The goal of talent scouting is also used to predict a high degree of likelihood of whether an athlete will be able to and successfully complete a

Ipang Setiawan
Doctoral Student, Post Graduate Dept., Universitas Negeri Semarang, Indonesia
e-mail: aguspurwanto.prof@gmail.com

training program in a selected sport in order to measure with certainty in carrying out the next stage of training [3].

Based on the above theories, the researcher tries to connect with the research problem to be raised by making observations in the field. The results of preliminary observations made by researchers in February 2019 at Pengprov Tarung Derajat Central Java, Jalan Guntur, No.3, Gajahmungkur District, Semarang City, obtained data that in the Tarung Derajat sport there is no standard test instrument in scouting talent athletes. potential athletes in Tarung Derajat, because in this physical test the instruments are used in general and are not consistent in every test implementation. In a focus group discussion (FGD) in July 2019, the speakers consisting of the main coach, Central Java coach, administrators, central administrators and administrators of Central Java said that the martial arts sport of fighting degrees does not have standard guidelines to measure the ability of athletes. And he also conveyed that there is a need for standard guidelines that must be possessed by a degree fighter[4].

Tarung Derajat sports talent scouting has simply been developed but is still not done intensively and specifically. The needs of components (such as biomotor, anthropometric, and psychological) in each athlete in various sports are different to increase their performance[5]. For example, in the sport of weightlifting, the dominance of the biomotor components needed is muscle strength, explosive power and balance. In addition, martial arts sports that require speed, reaction time, coordination and power, such as judo. In another article, fencing requires a talent scouting instrument consisting of a kinesthetic perception test, eye-hand coordination test, upper limb strength test, lower limb strength test, agility test and endurance test [6]. Whereas in Tarung the degree of dominance needed is muscle endurance, muscle strength, muscle explosiveness, agility, speed, besides that, although the required components are the same, the minimum requirement (passing grade) norms in each component in each sport are also different[7]

In another journal, Tarung Derajat self-exercise requires a contribution from the movement of the feet, hands and head that is carried out whether the lower body members (lowwersexremity) or upper limbs (upperextermitas), by paying attention to elements, namely endurance, strength, speed, accuracy, courage and resilience [8]. According to the results of observations and focus group discussions in August 2019, in the anthropometric element of degree fighting martial arts, the mastery of fighting techniques is supported by body structures, such as height, weight, leg length and arm length. The resource person also said that the body structure possessed by an athlete affects every movement in fighting. Athletes who have a good body structure will be able to move well, on the other hand athletes who have a poor body structure will find it difficult to move well in sports martial arts Tarung Derajat. The development of psychological aspects such as the development of intelligence, personality, motivation, behavior, attitudes, feelings, emotions, aspirations also affects the performance of Tarung Derajat athletes. The development of body structure, physical abilities, and psychologically gifted athletes together function in the maximum performance of Grade Fighting athletes.

The diversity of components in each sport is a discussion that needs to be addressed by sports experts, so that there can be no mistakes in determining potential athletes who have the talent to improve sports performance in Indonesia, including relatively new sports such as the Tarung Derajat sport. is an original Indonesian martial arts sport so that it is able to develop and excel in the international arena. In addition, based on the observation that the lack of literature on the sport of Tarung Derajat is also an obstacle experienced in determining potential athletes in increasing achievement, it also impacts on the lack of knowledge of athletes and coaches' knowledge of Tarung Derajat sports development. The lack of literature, research results, articles, journals and books about Tarung Derajat also affects the development of Tarung Derajat to be recognized by the public both nationally and internationally[9].

The final result of this research is in the form of a guide book for scouting the talents of Tarung Derajat athletes which contains items of psychological, anthropometric and biomotor test instruments, as well as test procedures, scoring guidelines for measurement results, interpretation of scoring results with standardized standardized assessment norms for athletes in the Tarung Derajat sport. . The instrument model for scouting the talents of Tarung Derajat athletes was developed with several assumptions, namely:

1. This research is the first step in developing a model of a talent scouting test instrument in the Tarung Derajat sport, because it is not yet available and the sport is relatively new.

2. To assist Tarung Derajat sports coaches and coaches in recruiting or selecting talented athletes by using a science and technology approach so as to obtain the right data or information.

The purpose of this research is expected to produce a product in the form of a talent scouting test model for the Tarung Derajat sport. Specifically, this research aims to:

1. Develop a model of the Tarung Derajat athlete scouting test instrument model.
2. Analyze the assessment of the talent scouting test which consists of the following stages: 1) determine the criteria for a good test, 2) analyze sports, 3) see the literature, 4) determine the test items, 5) complete the test instructions, 6) discuss with experts, 7) trials, 8) determine validity, reliability, and objectivity, 9) compile test norms, and 10) compile test guidelines to identify talented athletes in the Tarung Derajat sport.
3. Predicting the model of the Tarung Derajat sports talent scouting test instrument.

Method

Research on the instrument model of the talent scouting test for Tarung Derajat athletes produces a product in the form of a selection guide for Tarung Derajat athletes in the form of scoring results from anthropometric measurements (weight, height, arm length, leg length, sitting and standing height), biomotor (strength, endurance, speed, power, agility and flexibility) and psychological tests, as well as the norms for assessing the potential of a Talented Talent athlete[11]. The scoring norm is the standard value or the lowest score that a Tarung Derajat athlete must have. Psychological measurements are analyzed with the dominant factors of psychological conditions that must be possessed by talented Tarung Derajat athletes when going to and are competing, then anthropometric measurements are analyzed with anthropometric dominant factors which include height, weight, body mass index (BMI), thickness of body fat, and pressure. blood owned by Tarung Derajat athletes, while biomotor measurements were analyzed with the dominant factors of physical condition ability and motor skills possessed by Tarung Derajat athletes[12].

In accordance with the research objectives that have been formulated, the design used in this study is research and development. This research and development design follows the path developed which is based on a 4-D model consisting of of the 4 development stages namely Define, Design, Develop, and Disseminate. The basis for consideration of the type of research and development is used because to create a standardized and standardized model of the talent scouting test instrument in the Fighting Degree sport. Research and development designs were also chosen because they were oriented towards product novelty, not only emphasizing the test items, but also regarding test norms, procedures and processes, the content of which was in accordance with the characteristics in the field, so that products could be used easily, clearly, practically, safely., and is useful and effective to assist coaches in finding superior seeds in the Tarung Derajat sport[13].

The research and development procedure in this study is in accordance with the flow namely the 4-D development model (Four D Models). The development flow consists of 4 main stages of development, namely Define, Design, Develop, and Disseminate, or adapted into the 4-P model, namely definition, design, development, and distribution. The application of the main steps in the study is not only tracing the original version but according to the characteristics of the subject and the place of origin of the examinee. In addition, the model to be followed will be adjusted to the needs of development in the field. In the define stage, it is carried out with an initial analysis, namely a needs analysis in the field, at this stage a Focus Group Discussion (FGD) is carried out with experts, practitioners and coaches with a focus on the problem of achievement in the Tarung Derajat sport with the main problem of analyzing the problem of scouting talent in the branch. Tarung Derajat sports, analysis of the needs for superior seeds of Tarung Derajat athletes and concept analysis and formulating the goals of making the Tarung Derajat sports talent scouting test instrument. At this stage the analysis refers to literature study, factual observations, and analysis of dominance factors from branch achievement Tarung Derajat sport[14].

At the design stage, the preparation of instruments was carried out, analysis of the dominance of biomotor and anthropometrics in the Tarung Derajat sport, analysis of test items, analysis of test norms, selection of test procedure format and initial product design. Furthermore, the development stage in this study includes consultation on the initial product design to the supervisor, the stage of expert assessment and validation,

testing the product model of the Tarung Derajat talent scouting test instrument, and testing its effectiveness. The last stage, namely disseminate, is the stage of using the Tarung Derajat sports talent scouting test instrument model that has been developed on a broader scale in Tarung Derajat in Indonesia[15].

The data sources in this study consisted of prime r data and secondary data. Primary data were obtained from the analysis process of biomotor, anthropometric and psychological tests, input from several experts related to products and observations of the results of measuring the athlete's ability in both aspects while secondary data was obtained from data collection in the form of data analysis and documentation studies. The subjects of research and development of the Tarung Derajat sports talent scouting test instrument were 150 Tarung Derajat athletes registered in Central Java, totaling 150 people aged 10-14 years. The instrument in this study used theoretical instruments consisting of psychological tests and practical instruments consisting of anthropometric measurements and biomotor tests. Practical instrumentes use supporting media in the form of scales, meters, tape, cones, whistles, large and small bags, stopwatches, cameras and notebooks. All of these research instruments contain research focus and indicators to analyze the biomotor and anthropometric ability factors that seem to be contained in the problem formulation in this research[16].

To obtain primary data in this study, 2 types of data collection techniques were used, namely: 1) Biomotor and anthropometric measurement tests for Tarung Derajat athletes, psychological tests, 2) direct observations, and 3) FGD (Focus Group Discussion). Data collection techniques in FGD were conducted. as an expert assessment of the Tarung Derajat athlete scouting test instrument model using a Likert scale questionnaire sheet instrument with assessment indicators, namely 1) content substance factors (whether or not appropriate to the characteristics of Tarung Derajat athletes, and 2) implementation factors (convenience, safety, clarity, practicality, effectiveness and benefits) [17].

Respondents in this study to validate the product model of the talent scouting test instrument for Tarung Derajat athletes consisted of Dr. Taufik Hidayah M.Kes, Drs. Sri Haryono M.Or and Donny Wirayudha M.Pd., P.hD, and Main Trainers of Central Universities Drs. H. Heru Hermawan, Central Java Tarung Derajat Expert, Drs. R. Arif Agung Wiranata S.H. and the main trainer of Tarung Derajat Central Java, Madi Sudrajat S.H. Checking the validity of the research data was carried out by previously preparing the test items based on predetermined indicators for test development. The preparation of the test items is accompanied by the preparation of a standard test implementation or procedure and how to evaluate it. Followed by an expert judgment on the indicators and item arrangement of the Tarung Derajat athlete scouting test instrument, each variable based on standard test implementation procedures.

At the design stage, the preparation of instruments was carried out, analysis of the dominance of biomotor and anthropometrics in the Tarung Derajat sport, analysis of test items, analysis of test norms, selection of test procedure format and initial product design. Furthermore, the development stage in this study includes consultation on the initial product design to the supervisor, the stage of expert assessment and validation, testing the product model of the Tarung Derajat talent scouting test instrument, and testing its effectiveness. The last stage, namely disseminate, is the stage of using the Tarung Derajat sports talent scouting test instrument model that has been developed on a broader scale in Tarung Derajat in Indonesia[18].

The data sources in this study consisted of prime r data and secondary data. Primary data were obtained from the analysis process of biomotor, anthropometric and psychological tests, input from several experts related to products and observations of the results of measuring the athlete's ability in both aspects. while secondary data was obtained from data collection in the form of data analysis and documentation studies. The subjects of research and development of the Tarung Derajat sports talent scouting test instrument were 150 Tarung Derajat athletes registered in Central Java, totaling 150 people aged 10-14 years. The instrument in this study used theoretical instruments consisting of psychological tests and practical instruments consisting of anthropometric measurements and biomotor tests. Practical instrumentes use supporting media in the form of scales, meters, tape, cones, whistles, large and small bags, stopwatches, cameras and notebooks. All of these research instruments contain research focus and indicators to analyze the biomotor and anthropometric ability factors that seem to be contained in the problem formulation in this research[19].

To obtain primary data in this study, 2 types of

data collection techniques were used, namely: 1) Biomotor and anthropometric measurement tests for Tarung Derajat athletes, psychological tests, 2) direct observations, and 3) FGD (Focus Group Discussion). Data collection techniques in FGD were conducted. as an expert assessment of the Tarung Derajat athlete scouting test instrument model using a Likert scale questionnaire sheet instrument with assessment indicators, namely 1) content substance factors (whether or not appropriate to the characteristics of Tarung Derajat athletes, and 2) implementation factors (convenience, safety, clarity, practicality, effectiveness and benefits) [20.]

Respondents in this study to validate the product model of the talent scouting test instrument for Tarung Derajat athletes consisted of Dr. Taufik Hidayah M.Kes, Drs. Sri Haryono M.Or and Donny Wirayudha M.Pd., P.hD, and Main Trainers of Central Universities Drs. H. Heru Hermawan, Central Java Tarung Derajat Expert, Drs. R. Arif Agung Wiranata S.H. and the main trainer of Tarung Derajat Central Java, Madi Sudrajat S.H. Checking the validity of the research data was carried out by previously preparing the test items based on predetermined indicators for test development. The preparation of the test items is accompanied by the preparation of a standard test implementation or procedure and how to evaluate it. Followed by an expert judgment on the indicators and item arrangement of the Tarung Derajat athlete scouting test instrument, each variable based on standard test implementation procedures.

Results and Discussion

Various studies on talent scouting in martial arts have been widely conducted. Researchers have conducted several searches on the research that has been carried out that have relevance to the theme raised by the researcher. This is done, among others, so that researchers have a critical understanding and provide information on the differences and linkages of research being carried out by researchers. Young judo athletes consider criteria such as physical condition and body coordination in each of their technical skills so that the determination of training levels can be chosen appropriately according to the abilities possessed by individuals[21]. Selection tests must be carried out through a sports training organization. Children's sports talents must pay attention to differences in test items that must be carried out such as tests of technical skills, motor skills and morphological characteristics in a set of sports choices[22]. The physical test model which is valid and reliable for breeding and coaching prospective badminton athletes consists of 7 forms of physical tests, namely: (1) sit and reach test; (2) speed test (sprint 30 m); (3) leg muscle power test (vertical jump); (4) agility test (running 4 corners); (5) arm muscle power test (throwing a 2 kg medicine ball); (6) reaction test (step test); (7) endurance test (running distance of 600 meters). Reliability test results obtained (a) flexibility test (sit and reach) 0.743; (b) speed test (30 m run) 0.844; (c) leg muscle power test (vertical jump) 0.663; (d) agility test (running 4 corners) 0.848; (e) arm muscle power test (throwing ball) 0.943; (f) reaction test (step test) 0.987; (g) endurance test (600 m running) 0.861. The test is feasible to use in Indonesia because it meets valid, reliable, and objective requirements. (b) The criteria for athletes based on the physical test model are athletes who have a very good average total score. The test model prepared is in accordance with the characteristics of child growth and development based on discussions with expert judgment. The test is able to classify athletes according to their potential. Potential athletes are grouped based on the established test norms. Abbott (2007). In scouting talent, psychological factors in athletes are also very important because they relate to the way an athlete behaves when and will compete in the arena. The surrounding environmental conditions will have a big effect on his appearance when competing. [23]

Based on the explanation of the literature review above, it can be concluded that the psychological, anthropometric, and biomotor conditions in the scouting of athletic talent are the dominant elements that must be a requirement to be identified. Each sport has a predominance of different psychological, anthropometric, and biomotor components to support high-achieving athletes, therefore the procedure for testing and measuring talent scouting must be carried out systematically and according to the needs needed to identify individual talents. Before making a test, things that must be considered are (1) reference criteria for norms and measurements that must be used and (2) must have good test criteria. The test in question is a test that meets the requirements of validity, reliability, objectivity, discrimination, and reliability.

Tarung Derajat sport is an art of rapid reaction self-prowess that learns and trains techniques, tactics and strategies for movement, hands, fists and other body parts practically and effectively in defense and attack training patterns and forms, with the ability of muscles, brain and conscience in order to master a self-defense that contains

5 (five) elements of a unique movement force, namely: strength, speed, accuracy, courage and tenacity[24]. The Tarung Derajat martial arts sport was initiated on July 18, 1972 which is a work created by an Indonesian son, Guru Haji Achmad Dradjat, who has the nickname AA BOXER. This sport was born as a self-contained martial art that has its own flow and forum, is not affiliated with other sects and other martial arts organizations, both those existing in Indonesia and those outside the State of Indonesia and it is also emphasized that the Tarung Derajo sport does not adopt and is not a combination of other martial arts and does not appear by itself, but has a historical origin and a personal source of life that comes from the greatness and majesty of God Almighty as the only essential element and is very influential in shaping "Human identity. as well as the identity of something else "according to His will. Attending Tarung Derajat since it has become a demand as a learning process in the demands of training at the community level, the Central College or operation in the Training Unit (Satlat) must have an outline of learning as the core basis of demands pock ulum. As the core curriculum of Tarung Derajat, a systematic training material has been arranged in stages (kurata) starting from curve I to curve VII and level[25].

Competition Rules in the Tarung Derajat Sports Branch: In a competition, each sport has its own rules so that the match can run well or the term in sports is called fair play. In the Tarung Derajat sport itself, the rules that apply are for every technique used in the match, because the technical rules are enforced so as not to get out of the rules in the Tarung Derajat sport. Some of the techniques that are regulated, namely in the hand technique, all strokes learned in Tarung Derajat may be used, including 1) a quick hit, 2) a circle strike, 3) a fist hit and 4) a jolt. Another hand technique that is allowed is the hand drop technique.

Whereas the foot technique is used in two functions, namely kicks and drops (to withstand the opponent's attack). The kicks allowed to be used in combat are 1) inner and outer ring kicks, 2) side kicks, 3) back kicks, 4) front hook kicks, 5) back hook kicks and 6) back curling kicks. All kicks can be used with the jumping technique. The target application of the attack starting from the waist (belt) and above will be scored with the target direction of the front and sides of the body or head. The parts that are prohibited from being attacked are 1) around the groin, 2) behind the head and 3) behind the body. The imposition of targets outside the above provisions will receive a reduction in value and even be expelled from the battle arena and declared defeated.

Biomotor Dominant Factors in Tarung Derajat Sports: There are 7 aspects of physical or biomotor conditions that are dominant in Tarung Derajat sports, namely 1) abdominal muscle endurance, 2) abdominal muscle strength, 3) agility, 4) arm muscle endurance, 5) muscle explosiveness and 6) speed, and 7) flexibility. Based on the results of the research that has been done, it is concluded that male abdominal muscle strength is 60% in good category with 10 athletes, an average of 52.6 in moderate category. The strength of the abdominal muscles for women was 100% in the moderate category with 5 athletes, the average was 42.6 in the moderate category. 50% of male togok flexibility with enough category with 10 athletes, an average of 14.45 categories is sufficient. Female togok flexibility is 60% less category with 5 athletes, average 14.48 category less[26].

Male arm muscle endurance was 60% in good category with 10 athletes, with an average of 54.5 in good category. Female arm muscle endurance was 100% good category with 5 athletes, with an average of 58.4 good category. The endurance of male abdominal muscles is 70% very good category with 10 athletes, an average of 60.7 categories is very good. The endurance of women's abdominal muscles is 100% very good category with 5 athletes, an average of 55.6 very good categories. The male speed of 60% was in the good category with 10 athletes, an average of 4.37 seconds in the moderate category. 80% women's speed is in the very good category with 5 athletes, an average of 4.46 seconds is very good category. Agility of men was 40% in very good category and 40% in good category with 10 athletes, an average of 12.34 seconds in good category. Agility of women 60% very good category with 5 athletes, an average of 12.79 seconds in good category. Male VO2 Max was 60% in moderate category with 10 athletes, the average was 53.61 in moderate category. Female VO2 Max test was 60% in good category with 10 athletes, an average of 51.59 in good category.

Tarung Derajat is an aggressive and dynamic martial art in the forms of punching, kicking, blocking, and avoiding movements. Physical conditions greatly affect the performance of athletes when competing, where Tarung Derajat is a full body contact martial arts sport in which every athlete requires maximum physical condition. These seven aspects are the dominant biomotor components that every Tarung Derajat athlete must have. The role of abdominal muscle strength is very important

in every movement in the Tarung Derajat competition, including in the movement of the fight when making punches and kicks where the strength of the abdominal muscles plays a role in maintaining body balance and as a support for other limbs, because when hitting and kicking the body must be in a balanced condition. In a Tarung degree, flexibility is a combination of punch and kick movements, where flexibility of the legs will be very affective in kicking maximally. In the Tarung Derajat competition, good endurance ability of the arm muscles is also needed to carry out the hitting motion for a long time. By having good muscle endurance ability, the hitting movement will be stable in fighting and will be maximized[27]

Other elements of the dominant biomtoric component are also found in the endurance of the abdominal muscles. The movements in Tarung Derajat combat are dynamic movements, in which the punching and kicking movements must be combined. Therefore, the body must have a level of endurance and balance for a long time when fighting, and it will support the body to be more balanced and keep the body standing firmly. In addition, in the Tarung Derajat sport, it must have good speed, because a fighter who has good speed will be able to make punches and kicks with high speed towards the opponent and will also make it easier to make fighting steps. So that speed is the main physical component in the physical condition of Tarung Derajat. Furthermore, in Tarung Derajat, the ability to move is a priority, one of which is the ability in agility, because in fighting, movements are always combined both hitting and kicking with continuous flow. By having good agility, the ability to move in a fight is also more optimal and varied. Finally, VO2Max is also an important asset for Tarung Derajat, because a good VO2Max is also one of the main basic assets for a fighter to do long activities without causing fatigue which means in other words aerobic endurance (endurance aerobic). In a Tarung Derajat match there are 3 rounds in each round for 3 minutes (3 x 3 minutes), requiring the fighter to always be in good endurance.

Punching Techniques in Fighting Degrees When Competing: The effectiveness of a hit is a compound of strength (stomp), speed (burst), and accuracy (point of aim). The last two movements, pulling the arm and returning to the alert position, are carried out to carry out a follow-up attack or anticipate the opponent's movement. As mentioned above, since the accuracy of the hit is determined by the "arm shot," the line formed from the base of the arm and fist must be firmly aimed at the point of target. for example the target point on the face is the point between the eyes, eyes, nose, chin, ears and neck. The shape of the existing target point is adjusted to the hit point. The tip of the fist that has an elongated contact point is suitable for use for similar target points, for example in the eyes, nose, temples, ears and jaws to reach the target point on the face which is relatively difficult, it requires good and correct practice.

Conclusion

Physical conditions greatly affect the performance of athletes when competing, where Tarung Derajat is a full body contact martial arts sport in which every athlete requires maximum physical condition. These seven aspects are the dominant biomotor components that every Tarung Derajat athlete must have. The role of abdominal muscle strength is very important in every movement in the Tarung Derajat competition, including in the movement of the fight when making punches and kicks where the strength of the abdominal muscles plays a role in maintaining body balance and as a support for other limbs, because when hitting and kicking the body must be in a balanced condition. In a Tarung degree, flexibility is a combination of punch and kick movements, where flexibility of the legs will be very affective in kicking maximally. In the Tarung Derajat competition, good endurance ability of the arm muscles is also needed to carry out the hitting motion for a long time. By having a good muscle endurance ability, the hitting movement will be stable in fighting will be maximized. Another dominant biomoral component is also found in the endurance of the abdominal muscles, the movements in Tarung Derajat combat are dynamic movements, where the hitting motion and kicking must be combined. Therefore, the body must have a level of endurance and balance for a long time when fighting, and it will support the body to be more balanced and keep the body standing firmly. In addition, in the Tarung Derajat sport, it must have good speed, because a fighter who has good speed will be able to make punches and kicks with high speed towards the opponent and will also make it easier to make fighting steps. So that speed is the main physical component in the physical condition of Tarung Derajat. Furthermore, in Tarung Derajat, the ability to move is a priority, one of which is the ability in agility, because in fighting, movements are always combined both hitting and kicking with continuous flow. The model of the talent scouting instrument model for Tarung Derajat athletes has limitations in development

such as the subject for which the data is taken is only in the province of Central Java, therefore it needs to be developed with a wider sample nationally. The limitations of the development of the Tarung Derajat athlete scouting test instrument model only cover the psychological, anthropometric and biomotor areas, not to the aspects of measuring basic techniques and strategies to compete in athletes or the broader scope of talent scouting.

The Effect of Health Services, Supervisory and Team Orientation, Personnel Development and Tolerance of Error on Job Satisfaction Head of Health Centre in South Sulawesi Province

Wardiah Hamzah[1,2], Suryanto[3], Oedojo[4], Sukri Palutturi[5], Nasruddin Syam[2]

[1]Doctoral Student in the Public Health Doctoral Program, Faculty of Public Health, Airlangga University, Surabaya, Indonesia, [2]Lecturer in the Faculty of Public Health, Universitas Muslim Indonesia, Makassar, Indonesia, [3]Lecturer in the Faculty of Psikology, Airlangga University, Surabaya, Indonesia, [4]Lecturer in the Faculty of Public Health, Airlangga University, Surabaya, Indonesia, [5]Lecturer in the Faculty of Public Health, Hasanuddin University, Makassar, Indonesia

Abstract

Introduction: The Head of the Health Centre in carrying out his duties as the leader of the Health Centre has a health services, supervisory and team orientation, personnel development and tolerance of error that supports Health Centre employees in providing maximum health services so as to create job satisfaction within the Health Centre Head.

Method: Survey research with cross sectional study design conducted in a period of 3 months in the province of South Sulawesi. Samples were taken based on proportional random sampling with a total of 164 samples from 458 Health Centre heads in South Sulawesi. Data were collected by filling out the health services, supervisory and team orientation, personnel development and tolerance of error and job satisfaction.

Results: Health services have a significant effect on job satisfaction of the head of the Health Centre (p = 0.004).Likewise, supervisory and team orientation significantly affected job satisfaction (p = 0.000).Personal development also significantly affects job satisfaction (p = 0.001). The tolerance of error significantly affects the job satisfaction of the head of the Health Centre in South Sulawesi (p=0.044).

Conclusion: There is a significant influence on Health services, Supervisory and team orientation, Personal development and Tolerance of errortoward job satisfaction at the head of the Health Centre.

Keywords: *Job satisfaction, health services, supervisory and team orientation, personnel development and tolerance of error.*

Introduction

The quality of health services is measured by the criteria of organizational performance and the performance of health workers. So that the quality of Health Centre services can be guaranteed, the minister of health issues Ministry of Health No. 46 of 2015 concerning Health Centre accreditation. Health Centre accreditation aims to foster improvement in the quality of performance through continuous improvement of the management system, service delivery system and programs and the application of risk management[1].

Health Centre that have been accredited in 2017 in Indonesia were 4,223 (42.98%) Health Centre from

Corresponding Author:
Suryanto
Lecturer in the Faculty of Psikology, Airlangga University, Surabaya, Indonesia
e-mail: suryanto@psikologi.unair.ac.id

9,825 Health Centre, while in South Sulawesi Province there were 271 (60.08%) Health Centre that had been accredited from 451 Health Centre in 2017[2]. One standard assessment instrument in Health Centre accreditation is Health Centre leadership and management, where quality improvement is a task that must be carried out by Health Centre leaders. The Head of the Health Centre functions as a manager who carries out managerial functions ranging from planning, organizing, implementing activities, monitoring to evaluating all activities at the Health Centre[3].

The status of Health Centre accreditation describes the level of Health Centre performance and the Health Centre head as the Health Centre leader. Research Bakan, *et al*., (2014)[4], that job satisfaction has a positive effect on work performance and commitment. The higher the job satisfaction of a person, the more the performance results. This study is further strengthened by the findings of Inuwa, M [5], finding a positive and significant relationship between job satisfaction and performance

Job satisfaction is the extent to which individuals feel positive or negative about their work. It is an emotional response to one's duties, as well as the physical and social conditions of the workplace. In concept, job satisfaction also shows the extent to which expectations in one's psychological contract are fulfilled[6]. Therefore, job satisfaction is the final attitude or feeling that the head of the Health Centre has towards the job as the head of the Health Centre .

Supervision and guidance efforts that are still lacking by the head of the Health Centre and the career development efforts of Health Centre employees, which are relevant to supportive leadership practices. Supportive leadership practice is a leadership style that focuses on the concerns, needs and welfare of employees[7]. Where employees can work well so that organizational goals can be met. Supportive leadership practice is directly related to job satisfaction,[7,8,9,10]. This shows that high supportive leadership practices will increase jobs satisfaction of the head of the Health Centre which will have a high performance impact. Supportive leadership practices consisting of Supervisory and team orientation, Personal development and Tolerance of error.

Materials and Method

This is a survey research with cross sectional study design model that was carried out in 24 districts/cities in South Sulawesi Province. The population of this study were all active Health Centre heads working in South Sulawesi Province when the study was conducted. The total population was 458 people. Samples for each district/city were taken based on proportional random sampling with a sample size comprised 164 samples based.

This study uses 3 independent variables namely (1) Health services, (2) Supervisory and team orientation, (3) personnel development (4) tolerance of error . The dependent variables of the study, is job satisfaction which consist of several (indicators, namely: job security, recognition, social environment and adequacy of authority).

Results

Characteristics of Respondents:

Table 1. Characteristics of Respondents

Characteristics		Category	n	%
Health Centre	Category of Puskeesmas	Urban	53	32,3
		Rural	72	43,9
		Remote	32	19,5
		Very Remote	7	4,3
	Status of akreditasi	Non Akreditasi	14	8,5
		Dasar	50	30,5
		Madya	86	52,4
		Utama	13	7,9
		Paripurna	1	0,6

Characteristics		Category	n	%
Head of Health Centre	Age	30 – 39 years	33	20,1
		40 – 49 years	82	50,0
		≥ 50 years	49	29,9
	Gender	Male	86	52,4
		Famale	78	47,6
	Education Level	Diplome	5	3,0
		Bahelor	101	61,6
		Magister	58	35,4
	Work period	≤ 10 years	31	18,9
		11 – 20 years	58	35,4
		21 – 30 years	64	39,0
		≥ 31 years	11	6,7

Statistical Analysis Results: Liner regression test is used to analyze the effect of Health services, Supportive Leadership Practices, Supervisory and team orientation and Organizational emphasis on personnel development on Job Satisfaction. The results are as follows:

a. Simulant Test (F Test)

Table 2. Statistical Analysis Result (F Test)

Model	Sum of Squares	df	Mean Square	F	Sig
Regression	2433.135	3	811.045	20.700	0.000

Tolerance of Error	-0.620	0.306	-0.160	-2.031	0.044

Discussion

Health Centre Characteristics: The most Health Centre category was in the rural category at 43.9% and the least was in the very remote category at 4.3%. This shows that the category of Health Centre in South Sulawesi is mostly distributed in rural areas and a small proportion of the category of Health Centre in very remote areas.

The highest Health Centre accreditation status was in the madya category as much as 52.4%, while for the Paripurna category it was 0.6% which was the lowest distribution for the Health Centre accreditation status. Based on this, it can be concluded that the Health Centre accreditation status needs to be upgraded to the Paripurna category.

Responden Characteristics: The age of the head of the Health Centre was mostly in the age group of 40-49 years at 50.0%, 52.4% were male and Bahelor education level of 61.6%. The working period of the head of the Health Centre is at most in the 21-30 year category.

Influence Health services, Supervisory and team orientation, Personal development and Tolerance of error **toward Job Saisfaction**

a. Health services: Health services in this study are the extent to which the head of the Health Centre does the planning in improving health services at the Health Centre . The results of the study found that there was an effect of health services on the job satisfaction of the head of the health center (0.004).

The head of the Health Centre provides input and makes improvements to the program planning that has been made by the person in charge of the program. The programs/activities in the Health Centre are based on Permenkes No. 43 of 2016 regarding the minimum service standards in the health sector which consist of individual health efforts and community health efforts.To improve public health status, each Health Centre has one development health effort, but sometimes the district/city health office wants all development health efforts to be carried out at the Health Centre .

b. Supervisory and Team Orientation: Supervisory and team orientation in this study is the extent to which the Head of Health Centre supervises team performance including freedom of work, task supervision and team collaboration. The results showed that there was a significant effect of supervisory and team orientation on job satisfaction (p = 0,000)

Supervisory and team orientation such as task supervision affects job satisfaction, Health Centre heads are satisfied with their work in terms of supervising every task of Health Centre employees. The supervisory function carried out by the head of the Health Centre starts from planning activities, implementing activities to evaluating activities. The supervision of the head of the Health Centre on the activities in the Health Centre is that all activities do not fall outside the goal of the Health Centre as the spearhead of health services in the community.

According to Roades & Eisenberger (2002)[13], supervisory support refers to the behavior of supervisors in helping employees to demonstrate their skills, knowledge and attitudes. In this case, the supervision carried out by the head of the Health Centre on the work behavior of Health Centre employees encourages employees to demonstrate their skills and knowledge in providing health services. Without supervision, employees tend to lose focus at work. Thus, Health Centre staff need supervision from the head of the Health Centre, so that they can provide maximum health services.

c. Personnel Development: Personnel development is the extent to which the Head of the Health Centre helps Health Centre employees develop their talents and abilities, including education, training and seminars. The results showed that there was a significant influence of personnel development on job satisfaction (p = 0.001)

Personnel development also affects the job satisfaction of the head of the Health Centre [14], in the form of including Health Centre employees in seminars that support their competence. The head of the Health Centre is satisfied, if he can include Health Centre staff in seminars that help improve their abilities, in implementing health services at the Health Centre . Training can help Health Centre employees improve their skills and knowledge. In addition, local government regulations in several districts/cities require Health Centre employees to attend training with a frequency of one training each year, for the development of employee competencies.

The Head of the Health Centre in proposing Health Centre staff to take part in training based on an analysis of personnel needs, by looking at the competence of existing personnel. The head of the Health Centre proposes to the district/city health office, then the proposal will be followed up based on the availability of the budget. In addition to the training proposal from the head of the Health Centre, the district/city health office can directly appoint Health Centre staff who will take part in the training based on an analysis of the needs for personnel at the district/city level.

d. Tolerance of Error: Tolerance of error is the extent to which the Head of the Health Centre tolerates employees who make mistakes, including work errors, giving rewards and verbal warnings. The results of the linear regression test showed that there was a significant influence between tolerance of error on job satisfaction (p = 0.044).

Rewards are given in the form of praise and support for the results achieved by Health Centre employees. The head of the Health Centre sends outstanding Health Centre employees by participating in the

selection of outstanding health staff at the district/ city or provincial level, which is carried out annually by the district health office or the provincial health office.

Giving warnings to Health Centre employees who commit violations is carried out in stages, starting from an oral warning to a written warning. If the Health Centre staff does not respond to a written warning up to three times, the head of the Health Centre will delegate the problem to the district/city health office.

Conclusion

Health services, Supervisory and team orientation, Personal development and Tolerance of errorhave a direct effect on the job satisfaction of the head of the Health Centre in South Sulawesi Province. Thus, it is recommended that the head of the Health Centre prioritize supportive leadership practices, particularly the interests and needs of Health Centre staff in encouraging career development through education, training and seminars. It is recommended to the head of the Health Centre in implementing supportive leadership practices, especially the tolerance of error variable to be wiser in giving warnings, while still paying attention to applicable regulations.

Abtract

The purpose of this research is to make standardization of the basic movements of the pathol martial arts sport which is intended to identify the basic movements of the pathol martial arts by using logical science principles so that it can be used/played by everyone, then it can provide convenience in its development so that the traditional Pathol martial arts can be easily learned by the public. In general, the research approach used in this research is descriptive qualitative using a case study research design. This approach is used because the focus is on testing one phenomenon, namely the basic motion of the pathol nest martial arts. It takes careful preparation in determining participants, places, and data collection because this research is changing and developing according to changes in findings in the field. a place where researchers conduct research. This research was conducted in the coastal area of Sarang sub-district (Bajingjowo village, Temperak village, and Karangmangu village), which is the only area that still maintains the pathol nest martial arts. The focus of this research is to examine in depth the classification of the basic movements of pathol martial arts through identification and then analysis by paying attention to scientific principles that will produce standard pathol basic motion. This research is studied through philosophical studies, sociological studies, motor learning studies, sports biomechanics studies, and psychological studies. Standardization of the basic motion of the pathol is carried out by transforming the existing basic motion which is then developed to become a standard basic motion which is mutually agreed upon between the elders, midfielders, players and members of the pathol community so that it can be accepted by all levels.

Keywords: *Basic Movement, PatholSarang, Self Defense.*

Introduction

Martial is derived from the word martial means to maintain or defend, while self means resting on the soles of the feet or it can also be interpreted physically or mentally. Martial arts can be interpreted as an effort to maintain survival, guard physically or mentally from external disturbances[1]. Martial arts are growing and developing throughout the world with each region having its own characteristics in its movements. The development of martial arts today is growing rapidly with the number of martial arts that have become sports and are competed in sporting events at the SEA Games, Asian Games and Olympics. The Olympics are an important sports competition in the world. Martial arts such as boxing, judo, taekwondo, fencing, and wrestling account for 25 percent of all medals contested in the Olympics, and karate will be included in the Tokyo Olympics in 2020[2]. This does not mean that all martial arts are growing rapidly in various countries, there are still many traditional martial arts which is the national cultural heritage of each region that has not been known to the general public and even some have almost been eroded by time. The existence of traditional martial arts has begun to be eroded by the swift currents of modernization. The traditional martial arts is a marker of a different dimension, which is also a challenge for cultural elements and limited interactions between the imaginary and the body. Martial arts are examples of

e-mail: aguspurwanto.prof@gmail.com

body culture that are considered as collective symbolic assets, spread through several movement techniques and related to the habits of cultural or social groups. Martial arts combine uniqueness and adaptation with the cultural framework of a society, besides that it is a form of symbolic capital and a marker of values that are different from cultural legitimacy. Rembang Regency is one of the districts in Central Java, which is located on the north coast of Java Island and borders the province of East Java. Rembang Regency has a language, accent, and art which is a combination of the arts and customs of the provinces of Central Java and East Java. The majority of the people of Rembang Regency work as fishermen because it is a coastal area adjacent to the sea. One of the districts in Rembang district which is the largest producer of fish is the Sarang district[3].

Sarang sub-district is one of the sub-districts in Rembang district which is located at the eastern tip of Central Java province and directly adjacent to East Java province. Sarang sub-district has a martial art which is a cultural heritage of Rembang district called pathol. Pathol used to be a traditional martial art that can be found throughout the coastal area from Rembang district to Lamongan district. As time goes by, pathol is currently only found in Sarang sub-district, so that pathol is better known as patholsarang. Pathol Sarang is a martial art similar to wrestling or sumo, which uses muscle strength to defeat its opponent. Patholsarang has a unique appearance that is not shared by other regions, namely the appearance of all male players. Until now, patholsarang function as entertainment, ritual means, performances and as an economic function[4].

Pathol martial arts have survived to this day even though it has been crushed by the times. Based on the results of interviews with the elders of Patholbapak Sugiyanto on November 25, 2018, stated that beladiripathol is currently only performed in ritual events such as sea alms, anniversary events of Rembang district and events from the Tourism Office. Mr. Sugiyanto is one of the pathol elders who is also the principal of SD Negeri Temperak, Sarang sub-district, Rembang district. He plays an active role in preserving beladiripathol in order to survive and from generation to generation. Sugiyanto stated that the purpose of pathol today is different from the past. In the past, Pathol was used as a place to find the strongest warriors and a place to bet, but now Pathol aims to maintain its existence in order to survive amid the pressure of globalization. Pathol, which used to be scattered on the coasts of Central Java and East Java, is now only left in the coastal areas of Sarang sub-district, this is due to the lack of elder figures who can pass on this martial art to their children and grandchildren. It was different from the Sarang sub-district which had an elder who was the strongest pathol at that time named Mbah Miran. MbahMiran together with mbah Imam Suwardi defended the pathol and eliminated the element of gambling by creating a "prisen" system in pathol. This system gave everyone who played Pathol the right to get prizes, both the winners and the losers with a ratio of the prizes that won were greater than the losers. This system can preserve beladiripathol until now in Sarang sub-district[5].

Mbah Miran's struggle in preserving pathol has been continued by Mr. Sugiyanto since 1990 by introducing pathol to the nation's future generations by including it in extracurricular activities at SD Temperak, Sarang district. Pathol extracurricular activities still exist today, but they are still limited to SD Temperak and have not developed to other schools. This is due to limited time and energy in developing the teaching curriculum so that it cannot be developed by the related education office. The Ngudi Budoyo community provides pathol players to be featured in both government and private events. Ngudi Budoyo community members are pathol players who are always appointed to represent pathols, appearing in official and unofficial events, but in terms of activities this community does not have regular activities or meetings to discuss pathol conservation. This is because there has been no effort from the government to help preserve pathol. Until now, the local government has only made pathol as a routine display in every Rembang district anniversary event or other official events, the rest has not been given special attention to preserving either development or other efforts related to pathol preservation[6].

The pathol martial arts played by the Ngudi Budoyo community are different from the pathol martial arts competed in sea alms events. Pathol martial arts by the NgudiBudoyo community emphasize the art of movement so that it is more beautiful to see because it is used for entertainment performances, while pathol martial arts at sea alms events use more technique and strength to beat opponents and become the strongest person. Pathol martial arts need to be developed for the preservation of the culture of Rembang district and Javanese coastal communities because culture contains elements of noble values that must be maintained and in the interest of the community at large. The current

condition of Pathol martial arts is decreasing and can only be found in Sarang sub-district, it takes efforts from various levels of society to the government, as quoted by the Ministry of Youth and Sports which states that traditional martial arts that are almost extinct must be developed and passed on to the nation's young generation, therefore the government central and regional as well as the community has an obligation to raise and re-develop traditional martial arts [7]

Pathol is a martial art that resembles wrestling using a belt. Several countries in the world also have traditional martial arts with similar playing characteristics to pathol which is more commonly referred to as "Alysh" belt wrestling. Belt wrestling has had the belt wrestling world championship followed by many countries. More than 50 countries took part in the belt wrestling world championship. Several countries that participated in this championship included Russia, Turkmenistan, Kyrgiztan, Kazakhstan, Uzbekistan, Tajikistan, Ukraine, Mongolia, Azerbaijan, Moldavia, Georgia, Belarus. Belt wrestling in each developing country according to the characteristics and history of that country. "Alysh" has been competed in the belt wrestling world championship which began in 2002 until now[8].

That waist belt wrestling has undergone many changes, related to compliance techniques, behavioral tactics during matches and competition organizational arrangements, but still retains its traditional character. Waist wrestling fulfills several socially defined functions, and first of all the function of the unity of international nations having different cultures and traditions. The difference between the "Alysh" Wrestling Belt and the pathol is that in the opponent's throwing/dropping motion, Alysh can use his feet to tackle while pathol is not allowed. The grip of the belt by the hands on Alish is by wrapping the hands into the belt, while in pathol only wrapping the hands from the outside. Alysh martial arts are preserved by Kyrgyzstan, Turkey, Russia and the former Soviet Union and already have a world championship. Pathol martial arts are still underdeveloped and even threatened with extinction because currently it is only left in Sarang sub-district. The most striking difference is that pathol does not have basic movements, standard competition rules, and the organization that covers the pathol[9]. wrestling belt "Alysh", athletes compete in a standing position. Winning is awarded to the wrestler who makes the final technical action. All technical actions on the mat and ending on the mat are counted and scored. Belt tied at chest level. The remaining fist space between the belt and chest. Athletes hold each other's belts by thrusting their hands under the opponent's belts from the outside and fastening them to the hands. Feet can be used to tackle your opponent.

Pathol martial arts are still believed by the public to have a mystical element that cannot be explained through scientific theory. The mystical element here is due to the belief that weight has no effect on the results of pathol matches so that there is no weighing that causes small players to fight big players. This also affects the difficulty of Pathol martial arts being accepted and studied by today's society. Pathol as a martial art does not yet have standardized basic movements because every Pathol player uses different method in the match to defeat his opponent. Until now, there has been no joint training to improve skills in fighting pathol because there is no clear classification of pathol movements to improve competing skills. Pathol players, in this case the community immediately follow the match without the need for special preparation. Pathol also does not have a forum or organization to support it, therefore beladiripathol has not yet been able to develop and is even almost extinct. Research is needed in order to scientifically study the standardization of the basic movements of beladiripathol so that the basic form of motion and basic exercises can be known in depth. [10]

The process of standardizing the basic pathol movements is intended to identify the basic movements of Pathol martial arts by using the rules of logical science so that it can be used/played by everyone, then it can provide convenience in its development so that the now traditional Pathol martial arts can be easily learned by the general public. The standardization of basic pathol martial arts movements is also intended to develop pathol martial arts teaching materials as an effort to disseminate Pathol martial arts. The standardization of the basic pathol movements begins with the gathering of pathol elders, midfielders/referees, and members of the NgudiBudoyo community to equalize perceptions about the rules and basic movements of the pathol, after which the recording of the pathol martial arts movements is carried out. The process of standardizing pathol is intended so that pathol has a standard basic motion and is in accordance with the rules of scientific studies so that it can be accepted by the millennial generation and remains sustainable and develops in other areas. The standardization of the basic pathol movements that will be carried out is in the form of standardizing the pathol

movement which will be dressed with more interesting artistic movements, as well as making standard rules and a clear pathol organizational structure so that the pathol is easier to find and learn by the general public[11].

Problems in Pathol martial arts need to be solved through standardization of basic movements or basic techniques using sports science analysis while maintaining the characteristics of Pathol martial arts itself. The process of standardizing the basic motion of the pathol aims to preserve, develop, explore, and instill pathol as the culture of the Javanese coastal community. Standardization of the basic motion of the pathol is carried out by transforming the existing basic motion which is then developed to become a standard basic motion which is mutually agreed upon between the elders, midfielders, players and members of the pathol community so that it can be accepted by all levels. Research on the standardization of limited pathol basic movements reveals logical scientific elements in Pathol martial arts, ignoring mystical elements that cannot be explained through science[12]. Standardization is also carried out in the rules of class division in pathol matches so that they can be logically accepted by the general public. In accordance with the formulation of the problem put forward, the objectives of this study are:

1. Analyzing the philosophical basis of Sarang'spathol martial arts.
2. To analyze the sociological basis of Sarang'spathol martial arts.
3. To analyze the psychological basis of Sarang'spathol martial arts.
4. Analyzing the basic motion classification in Sarangpathol martial arts.
5. Analyze the basic motion standards in Sarangpathol martial arts.

Method

The research approach used in this research is descriptive qualitative using a case study research design. Case study research focuses on one selected phenomenon and wants to be understood in depth by ignoring other phenomena . Case research only covers a very narrow area or subject, but in terms of the nature of the research, case research is more in-depth[13]. This approach is used because the focus is on testing one phenomenon, namely the basic motion of the pathol nest martial arts. It takes careful preparation in determining participants, places, and data collection because this research is changing and developing according to changes in findings in the field. a place where researchers conduct research. This research was conducted in the coastal area of Sarang sub-district (Bajingjowo village, Temperak village, and Karangmangu village), which is the only area that still maintains the pathol nest martial arts. This research focuses on exploring data on pathol elders, pathol actors and coastal communities in Sarang sub-district. The focus of this research is to examine in depth the classification of the basic movements of pathol martial arts through identification and then analysis by paying attention to scientific principles that will produce standard pathol basic motion. This research is studied through philosophical studies, sociological studies, motor learning studies, sports biomechanics studies, and psychological studies[14].

Subjects in the research concept refer to respondents, informants who want to be interested in information or extract data, while the object refers to the problem or theme that is being researched. The subjects in this study included the head of the NgudiBudoyo community, elders of the nest pathol, pathol players, martial arts experts, cultural figures in Rembang district. The object of research is a scientific objective with specific objectives and uses to obtain certain data that has a different value, score or measure. The object of this research is Patholsarang martial arts. Sources of data in this study are divided into two parts, namely primary data sources and secondary data sources.

1. **Primary Data:** The data were obtained from pathol elders and community leaders Ngudi Budoyo. Primary data is the basic motion elements of pathol martial arts taken directly from the object, namely the elders of pathol through video recording which is then used to classify the basic motion of the pathol and analyzed by sports science.
2. **Secondary Data:** The data were obtained from members of the Ngudi Budoyo community and pathol players during performance practice and competitions to take videos and photos. Secondary data can also be obtained from coastal communities in Sarang sub-district, especially the villages of Karangmangu, Sarang Meduro, and Temperak.

This study uses several data collection techniques to avoid the weaknesses of one method with another so that accurate data is obtained. Data collection techniques used in this study were observation, interviews and documentation.

1. **Observation Technique:** The observations made in this study were the researchers took to the field to make direct observations of all activities and individual behavior at the research location. Researchers recorded and recorded everything that was obtained in the field using both structured and semistructured ways, namely by asking questions that you wanted to know and observing the basic movements of Pathol martial arts carried out by elders and pathol practitioners. In the observation technique, video recording of the basic motion of pathol martial arts was also carried out which would then be observed and analyzed through a sports science study[15].
2. **Interview Techniques:** Interview techniques are used to determine the responses of pathol players in conducting pathol matches regarding movements in pathol, as well as the hopes of pathol players in facing the era of globalization so that pathol will survive and not disappear. This interview is also used to construct people, activities, events, motivation, organization, demands and concerns; reconstructing activities that have occurred in the past, projecting what is expected in the future; verify, modify and expand information obtained from both humans and non-humans (triangulation); and verify, modify, and expand the constructs developed by the researcher for checking members[16].
3. **Documentation Techniques:** Documentation techniques aim to retrieve data through documents and records/videos of past events. Documents collected in this study were written materials related to pathol, both personal documents and official documents. Personal documents include a person's written notes or essays about his actions, experiences and beliefs (diaries, personal letters, and autobiographies regarding pathol), while official documents include internal documents (memos, announcements, instructions, rules of a community institution regarding pathol) and documents. external (magazines, bulletins, statements, and news broadcast by the mass media about pathol). Pathol record/video is used as supporting material in analyzing the basic motion study of pathol martial arts in biomechanics, motor learning and philosophy. The records here were not obtained at the request of the researcher, but rather the results from past videos about the implementation of Pathol.

    a. **Data Validity Test:** Checking the validity of the data in this study using triangulation techniques. Theory triangulation is carried out by cross-checking to ensure whether the data found in the field are appropriate. This technique is commonly used in qualitative research, because this technique reflects an attempt to gain a complete understanding of a phenomenon through examination from other sources. That is, researchers try to use multi-method so that the research is precise and more effective to increase the depth, breadth and strength of the research.

The triangulation technique in this study is that the researcher compares the observed data with the data from interviews with pathol elders, the head of the Ngudi Budoyo community, Pathol actors, and the coastal community of Sarang district, Rembang district. This study also recorded video to identify the basic motion of the pathol, then analyzed it using sports science and technology. Analysis of the components of pathol motion using Application Kinovea version: 0.8.15.0. The results of video recording were also compared with the basic motion video/pathol record of past documents[17].

Data analysis is a process of systematically searching and compiling data obtained based on field notes, interviews and documentation by organizing data into categories, describing them into units, synthesizing, arranging them into patterns, choose which ones are important and which ones will be studied and make conclusions so that they are easily understood by oneself and others. Data analysis is done by organizing data, decomposing it into units, synthesizing it, arranging it into patterns, choosing which ones to share with others[18].

The stages in this research, the data is processed from reduction, presentation (display), to drawing conclusions or verification. States that activities in qualitative data analysis take place continuously and are carried out interactively at each stage of the research to completion and until the data is saturated. Activities in data analysis, namely data reduction, display data, and conclusion drawing/verification[19].

Description of each of these activities, namely:

1. **Reduction:** Data reduction is a process of selecting, focusing on simplifying and transforming raw data that emerge from written records in the field. Data reduction begins when data collection is done by summarizing, coding, searching for themes, creating clusters, writing memos and so on with the intention of setting aside irrelevant data and information. The

data obtained from the field will be selected and sorted according to the object under study so that the data obtained is relevant.

2. **Presentation of Data:** Data presentation or display is a description of a set of structured information that provides the possibility of drawing conclusions and taking action. The presentation of qualitative data is presented in the form of narrative text.

Result and Discussion

The basic concept of the pathol nest martial arts is closely related to the concept of motion, where the concept of motion is related to the process of moving from the moving part of the body to how it moves. Movement in the pathol nest martial arts is studied through sports science and technology to determine its potential in martial arts, so that the relationship of the limbs and other body parts can be well known, where the body is a means of movement and is used as a weapon in martial arts both when attacking and defending.

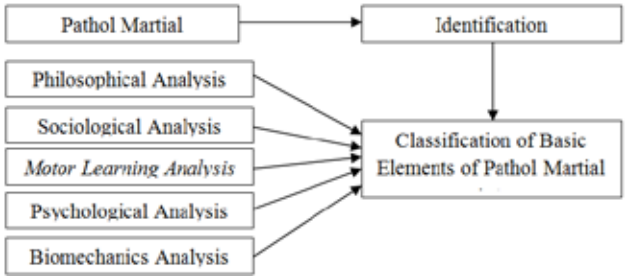

Figure 1. Thinking Framework

Pathol is a traditional wrestling sport originating from Sarang sub-district, Rembang district, Central Java. Pathol martial arts have existed since the Majapahit era, which was originally a competition event to find the best knights who could guard Tuban harbor, which at that time was full of pirates. Patholsarang means 'invincible', being an ancient wrestling martial art native to coastal communities in Sarang sub-district., Rembang district. In ancient times Sarang was included in the Duchy of Lasem when the Majapahit kingdom was still victorious. At that time Lasem was led by Bhre Lasem who was the younger brother of King Hayam Wuruk. Lasem is a duchy that has a sea area, so a navy was formed to strengthen its territory. Selection was held in the process of selecting soldiers as a navy, where the selection technique was carried out by fighting between two people, each of which was wearing a scarf tied around his waist. If the opponent is able to slam his opponent by holding the shawl tie, then he is declared the winner and escapes as a marine fleet soldier. Until now the patholsarang is still sustainable in the Sarang sub-district[20].

Knowing the history of the patholsarang, we can see that the regional culture in Rembang district is still sustainable. The ancient culture inherited from the Majapahit kingdom has survived hundreds of years ago, not lost due to the times. This further proves that the people of Rembang, especially Sarang, really care about the preservation of local culture. They keep it and even continue to introduce it to the younger generation. Dubnewick (2018) states participating in traditional games can enhance the sports experience of Indigenous youth by (a) promoting cultural pride, (b) interacting with Elders, (c) supporting connections to the land, (d)) develop personal characteristics, and (e)) develop the basis of the movement. It advances sports literature and provides the necessary insight into traditional games for sports programmers and policymakers.

Basic Movement of Nest Pathol: The tide stance in Pathol martial arts is carried out by standing upright with the arms beside the body and the legs straight up, then the left leg is lifted forward with the front leg bent slightly and the hind leg straight. The next tide stance is to pull the right leg behind it to the right side in line with the left leg. position of the legs are not parallel to the legs of the opponent when paired with the legs of the middle stance. The position of the pairs is a sign that the pathol player is ready to compete and is waiting for a signal from the midfielder, as in the image below which starts in Figure 1 and then continues in Figure 2**.**

Figure 2. Front mount

Figure 3. Middle mount

Stance: The stance in the pathol martial arts includes the middle stance and the side stance. The stance is used for both attack and defense. The movement of the stance in Pathol martial arts requires strong leg strength and strength because the essence in Pathol martial arts is to knock down the opponent so that the coordination of the legs in the stance must be good so that it is difficult to slam down when defending and easily knocks the opponent down when attacking.

Figure 4. Middle easel

Figure 5. Side stance

Step Pattern: The pattern of steps in Pathol martial arts is carried out before the match and during the match. The pattern of steps before the match starts with stepping your left foot forward, then stepping your right foot sideways parallel to your left foot. This pattern of steps indicates the player is ready to start the match and is waiting for a signal from the midfielder. The stride pattern during the competition includes the forward, backward, right side, and left side step patterns. This pattern of steps is used when defending or slamming an opponent.

Holding hands: Hand holding in Pathol martial arts is done by inserting the hand into the udhet/belt through the bottom. Hand holding must be strong because it is used to slam the opponent, besides that it can also be used as defense. Pathol martial arts are dominated by hand grip movements so this movement is very important to master.

Figure 6. Hand holding

Dings: The kick motion in pathol martial arts is a movement to pull the opponent to the right and left with a strong force to eliminate the balance of the opponent so that the opponent falls. The motion of throwing can only be done by holding the udhet/belt of the opponent and not allowed to hold anything else. Slamming is also not allowed by tackling or using your feet to kick your opponent.

Defences: The defensive movement in Pathol martial arts is carried out by taking a stance to withstand the throw from the opponent. Horses are carried out to adjust the direction of the opponent's throw, if the direction of the opponent's throw is to the right, then defend using a stance to adjust that direction to the middle stance or side with all his might.

Pathol Sarang Rules: Patholsarang's performance begins with the opening music using instruments in

the form of a ciblon drum, kempul, bonangloro, saron, demung and slompret, thus inviting the audience to see Patholsarang's performance. The pathol performance which was witnessed by many people was only led by a midfielder or referee in the middle of the arena. The singer arrives after the music is beating and dances to the rhythm of the piece (the sound of the gamelan). The two midfielders stopped dancing after the music stopped (sirep), after which each midfielder called his champion to play a match.

The hero who is ready to compete then takes off all his clothes except for the trousers he is wearing. Each Pathol or hero who has been stripped of his clothes is then given an udhet like a cloth to hold during the match. The udhet is worn around the stomach like a belt. After fulfilling the requirements in the match, the person is ready to do the match. The competitor who is ready while waiting for his opponent to be invited to dance by the midfielder around the arena. The dance is interpreted as a challenge to the co-star. After the opponent is ready, the fight begins, but before the champions fight, they are invited to dance by the midfielders around the arena to the accompaniment of music. The dance of a pair of fighters and stargazers is defined as the readiness that each fighter is ready to fight for strength. The sound of the gamelan stops as a sign that the two fighters are ready to take their respective positions to fight. The fighter sets a stance, the fighter's hands hold the belt (udhet) worn by the opponent. The fighters began to show their strength to each other. They try to slam each other with the strength of their hands that only rest on the belt. During the match, the two midfielders dance to motivate their heroes so that they are excited and win. The music accompaniment was still beaten continuously, the atmosphere was getting tense because of the crowd's screams cheering the champion.

The procedure for a pathol match is that if one of the fighters falls or is slammed, the fallen fighter is declared defeated and the match for that round is declared complete. The fighter who is declared the winner is the fighter who manages to knock down his opponent. It is said to fall if the opponent's back has touched the sand (the ground where the pathol took place). If the opponent falls but has not touched the sand and is still able to get up again, then the fighter still has the right to continue the match, otherwise if each fighter falls and both backs do not touch the sand then the match is considered a draw (single), so that the match is repeated no longer. who win or lose. Games that last for a long time are sometimes caused because neither fighter can beat the opponent at hand. Both fighters are equally strong and if something like that happens, the midfielder has the right to stop the match. The match that ended with the appearance of a winner was also very interesting. The losing fighters are immediately taken aside and out of the arena by their respective midfielders. The victorious fighter is also immediately invited to dance by the spectators in the arena. This dance of victory is a new form of challenge for opponents who lose and want to start the match again. The match will restart once there is an opponent who dares to beat the winner. The match goes on like the previous round until someone wins or loses. The match will not stop until someone is undefeated. The final winner in the match is called "Pathol", but if in the match neither win nor lose then the match is considered a draw (single) or both agree to stop and end the match led by the midfielder.

The foundations for the basic elements of the pathol martial arts basic: Patholsarang is a martial art such as wrestling or sumo which depicts a power battle between two bosses who are fighting over a kick. Tentang is a place to raise fish. Pathol was previously found along the coast of Rembang district to Lamongan. As time goes by, pathol is increasingly being abandoned so that now it can only be found in Sarang sub-district, Rembang district, therefore pathol is now better known as patholsarang. It is not impossible if the process of inheriting pathol martial arts in the nest does not go well, it will cause the pathol to disappear and become extinct from Indonesia because Sarang sub-district is currently the only area that still maintains pathol martial arts. Pathol martial arts inheritance is experiencing obstacles and is difficult to pass on to the current generation because the game system still uses elements beyond reason that believe in magic elements so that young people have difficulty accepting. The absence of a coaching system and a standard competition to regulate Pathol martial arts into modern ones that follow the times. The standardization of the pathol martial arts movement is an indispensable way of inheriting the pathol martial arts so that it can be easily accepted by all levels of society so as to avoid extinction. This standardization also aims to make it easier for the younger generation to learn Pathol martial arts that adapt to current developments. The standardization of the basic movement of the pathol nest martial arts is analyzed philosophically, sociologically, motor learning and biomechanics. The process of philosophical analysis

in the pathol nest martial arts is carried out by tracing data through interviews with pathol elders, Sarang sub-district communities and cultural observers so that it will be found how the forming factors of pathol martial arts can survive until now in Sarang sub-district. This data search was also used to explore the values contained in Pathol martial arts. This is very important because it can serve as a guide in practicing Pathol martial arts, so that everyone who practices and competes in Pathol can understand and apply the values contained therein where every aspect of Pathol martial arts is not only in the form of martial arts movements but also forms the human soul to become better.

Conclusion

Pathol martial arts need to be developed for the preservation of the culture of Rembang district and Javanese coastal communities because culture contains elements of noble values that must be maintained and in the interest of the community at large. The condition of Pathol martial arts is currently decreasing and can only be found in Sarang sub-district, it takes efforts from various levels of society to the government, as quoted from the Ministry of Youth and Sports which states that traditional martial arts which are almost extinct must be developed and passed on to the young generation of the nation, therefore the government central and regional as well as the community has an obligation to raise and re-develop traditional martial arts. Pathol martial arts are still believed by the public to have a mystical element that cannot be explained through scientific theory. The mystical element here is due to the belief that weight has no effect on the results of pathol matches so that there is no weighing that causes small players to fight big players. This also affects the difficulty of Pathol martial arts being accepted and studied by today's society. Pathol as a martial art does not yet have standardized basic movements because every Pathol player uses different method in the match to defeat his opponent. Until now, there has been no joint training to improve skills in fighting pathol because there is no clear classification of pathol movements to improve competing skills. Pathol players, in this case the community immediately follow the match without the need for special preparation. Pathol also does not have a forum or organization to support it, therefore beladiripathol has not yet been able to develop and is even almost extinct. Research is needed in order to scientifically study the standardization of the basic movements of beladiripathol so that the basic form of motion and basic exercises can be known in depth. The process of standardizing the basic pathol movements is intended to identify the basic movements of Pathol martial arts by using the rules of logical science so that it can be used/played by everyone, then it can provide convenience in its development so that the now traditional Pathol martial arts can be easily learned by the general public. The standardization of basic pathol martial arts movements is also intended to develop pathol martial arts teaching materials as an effort to disseminate Pathol martial arts. The standardization of the basic pathol movements begins with the gathering of pathol elders, midfielders/referees, and members of the NgudiBudoyo community to equalize perceptions about the rules and basic movements of the pathol, after which the recording of the pathol martial arts movements is carried out. The process of standardizing pathol is intended so that pathol has a standard basic motion and is in accordance with the rules of scientific studies so that it can be accepted by the millennial generation and remains sustainable and develops in other areas. The standardization of the basic pathol movements that will be carried out is in the form of standardizing the pathol movement which will be dressed with more interesting artistic movements, as well as making standard rules and a clear pathol organizational structure so that the pathol is easier to find and learn by the general public.

Legal Constraints on the Enforcement of Covid-19 Health Protocol in Indonesia

Husni[1], Mahdi Syahbandir[2], Muhammad Ya'kub Aiyub Kadir[3], Teuku Ahmad Dadek[4]

Abstract

The positive number of Covid-19 in Indonesia continues to increase and there are no signs of decreasing. This increase was triggered by the implementation of the new normal, long holidays and uncontrolled crowds. And none of this is accompanied by enforcement of health protocol laws (wearing masks, washing hands, maintaining distance and not crowding). This paper examines the legal constraints of enforcing health protocols with normative legal method through library research. The results of his research show firstly, the absence of positive laws that can be used as the basis for law enforcement of health protocols, causing bias in its implementation and health protocols regulated by the Minister of Health Regulation which is not part of the source of positive Indonesian law. Second, the recently issued legal regulations to regulate the enforcement of health protocols are not in accordance with the legal hierarchy prevailing in the Indonesian legal system. Third, specifically for crowd management, the police did not use their authority in accordance with the Criminal Code because it was not prepared to control the Covid-19 crowd, causing multiple interpretations and becoming polemic in the political realm. This study suggests that the Government of Indonesia enact a Government Regulation in Lieu of a Law on Health Protocol Enforcement and provide additional authority to regional heads (governors and regents/mayors) in determining disaster emergencies to also issue regional head regulations in lieu of regional regulations and so that district governments/city and province to propose regent/mayor and governor regulations to become regional regulations that get parliamentary approval.

Keywords: *Positive Covid-19, Legal constraints, Health protocol.*

Introduction

Introduction from March 2 to 10, December, 2020 positive cases in Indonesia had reached 592,900 people, 487,445 (82.2%) confirmed cured, 18,171 (3.1%) people died, the rest received hospital care and independent isolation on the spot, non hospital[1]. This increase occurred due to three factors. First, it was triggered by the Indonesian Government's policy that announced a new normal on July 1, 2020 without a strong legal certainty and legal relief approach in enforcing the Covid-19 health protocol. Across Indonesia, the new normal is interpreted as saying that Covid-19 has ended, which is shown by busy going to vacation spots, the culture of going home to a sharp increase, and many wedding parties are being held again. Second, during the Eid al-Adha holiday period on July 31, 2020, which runs from July 30 to August 2, 2020 and the long holiday from October 28 to November 1, 2020, where the government increases the holiday period for two days so that the holiday becomes four days[2].

This Eid al-Adha holiday triggered population mobility (going home) and returning home so that there was community contact with the local community and led to local transmission and it was proven that 15 days later the Covid 19 number had increased sharply and this was also not accompanied by strict enforcement of

e-mail: tadadek@gmail.com

health protocol laws and monitoring population mobility. The government is considered weak in controlling the mobility of people, which is the easiest route for the spread of the Covid-19 virus. In fact, there are many studies that prove that controlling people's mobility through transportation modes is very essential in the spread of Covid-19[3].

Third, the police did not use their authority seriously against Article 281 KHUP to disperse the crowd. The latest is the return of Habib Rizieq Shibab, chairman of the Islamic Liberation Front (FPI) who was picked up at Soekarno-Hatta Airport by nearly 50,000 people where the police could do nothing to disperse the crowd.

Health protocol enforcement can be carried out in two ways, namely socialization and law enforcement with imprisonment and fines. The Indonesian government is still taking socialization steps through printed media content, social media, distributing masks, and other activities. However, the number of Covid 19 continues to increase, this indicates that the socialization that was delivered to residents did not go according to expectations, in fact it was said that almost 70 percent of residents ignored this health protocol[4].

Health protocol law enforcement based on definite and legal formal laws has not been implemented in a structured and systematic manner. This problem not only arises in areas that have not implemented Large-Scale Social Restrictions (PSBB), but also occurs in areas that are implementing PSBB, such as the Special Capital Region (DKI), Jakarta. Therefore, the Provincial Government of the Special Capital Region of Jakarta has proposed and ratified that the governor regulation (Pergub) be upgraded to a regional regulation (perda), because it is in accordance with the legal hierarchy in Indonesia[5].

The Indonesian government strives to provide the meaning of legal certainty and legal legality for state officials that the health protocol can be enforced on a positive legal basis by issuing Presidential Instruction Number 6 of 2020 concerning Improved Discipline and Law Enforcement of Health Protocols in the Prevention and Control of Covid-19 which published on August 4, 2020 as an effort to provide legal certainty in health protocol law enforcement. The absence of legal regulations that are used as the basis for law enforcement is not yet available, causing a gray area, especially the uncertainty of legal regulations governing them, who is the implementer of the law, and how is the procedural law[5]

Then, this condition is exacerbated by the lack of public awareness to comply with health protocols, not to mention that there is distrust that Covid-19 does exist and is attacking. Head of the National Disaster Management Agency (BNPB), Doni Monardo, said that 44 million or 17% of Indonesia's population does not believe that Covid-19 exists[6]. Carter said that the law has an important influence on disasters, namely 1) as a formal basis for disaster management, 2) allocating and distributing the responsibilities and roles of each party legally, 3) providing national guidance, 4) providing adequate support. it makes sense for reasonable measures such as regulations for provision of funds, 5) provides broad and definite benchmarks, and 6) minimizes legal conflicts, especially in the course of an emergency.[7]

The real and real legal relations to disaster management are: 1) the law strengthens the government's obligations in disaster management; 2) engineering the community to have a culture of disaster awareness; and 3) law formulates mechanisms, organization, participation and international relations. Disaster law is inseparable from the government's disaster law politics. Dadek et al. has defined the politics of disaster law as, "As the government's legal options to enforce or not enforce legal regulations in disaster affairs to protect citizens in order to obtain their rights in disaster risk reduction, in emergencies, as well as to secure rehabilitation and reconstruction guarantees for their lives, as well as regulate all obligations.

Community elements in disaster management, and regulating legal mechanisms between institutions and the community in the pre-disaster, emergency, and rehabilitation and reconstruction processes.[8] "Therefore, as a preventive measure so that it can be measured and has legal certainty to break the Covid-19 chain, as a rule of law, Indonesia must compile a health protocol in the form of legal regulation.[9] The Indonesian government faces legal obstacles in enforcing the Covid-19 health protocol because existing legal regulations cannot provide a solid basis for enforcing health protocols. Meanwhile, regulations specifically made to punish health protocols do not comply with the hierarchy of legal products in Indonesia. Then, the enforcement of health protocols through health promotion faces obstacles, such as there are still people who think that Covid-19 does not exist and is just a conspiracy, in addition to rejection based

on the Islamic view that death and the fate of humans have been determined by Almighty God. In fact, there is a hadith of the prophet which states that "if a country is stricken with a plague, then do not go out of the country and into that country." The leader of the DayahDarul Mujahidin Aceh Utara, Tgk Muslim At-Thahiry asked Dayah Dayah in Aceh to refuse the distribution of masks from the Aceh Government.[10]

Materials and Method

The specification of this research is normative legal research that seeks to describe the legal structure and strength of legal sanctions and to analyze secondary data on the enforcement of Indonesia's Covid-19 health protocol. Sources of data in this study were obtained from literature studies and literature material studied in the form of statutory provisions, expert views, and related research results as well as current case developments. Literature review is carried out by examining legal materials (primary, secondary and tertiary legal materials) both in physical and electronic form. Data collected from library and field research were analyzed using legal and conceptual approaches. The regulatory approach is carried out on research results that have been regulated in statutory provisions, while the conceptual approach is carried out on research results that have not been regulated in statutory provisions.

Results and Discussion

Lack of Positive Law: Why is law enforcement of Indonesia's Covid-19 health protocol experiencing problems? One of the reasons is the unavailability of positive laws at the level of laws that specifically regulate health protocols (wearing masks, washing hands, maintaining distance and not crowding). While many health protocols are contained in the Decree or Regulation of the Minister of Health, and many health protocols are not only wearing masks, washing hands and maintaining distance, but also how to sneeze, change clothes at home and so on[11].

In the Indonesian disaster management subsystem that is related to Covid-19, there are various laws such as; Law Number 24 of 2007 concerning Disaster Management (UUPB) as the main regulation, Law Number 23 of 2014 concerning Regional Government (UUPD) also regulates disaster issues, especially covering disaster-prone areas (Article 36), filing regulations in natural disasters (Article 239), emergency funds (Article 296), and division of authority in disaster management between the central, provincial and district/ city levels (attachment), Law Number 23 Year 1992 concerning Health (UUK) which regulates disasters, especially regarding infectious diseases (Articles 28, 29, and 30) and epidemics (Article 31), Law of the Republic of Indonesia Number 4 of 1984 concerning Communicable Disease Outbreaks (UUW) which regulates outbreak areas, countermeasures, rights and obligations, as well as criminal provisions, Law of the Republic of Indonesia Number 6 of 2018 concerning Health Quarantine (UUKK) which regulates quarantine issues, one of which is caused by infectious diseases.

Then, the government also used constitutional authority for "compelling precariousness" by issuing Government Regulation in Lieu of Law (Perpu) of the Republic of Indonesia Number 1 of 2020 concerning State Financial Policy and Financial System Stability for Handling Pandemic Coronavirus Disease 2019 (Covid-19) and/or In the Context of Facing Threats that Endanger the National Economy and/or Financial System Stability which regulates State Finances and Financial Stability. This second group is based on the principle of centralization in handling impacts, health emergency status, quarantine mechanisms, and so on.[11]

In the legal system for disaster management in Indonesia, there has not been a single article that can be used as a legal basis in enforcing the Covid-19 health protocol. However, there are several laws that can be used as a reference in criminal enforcement related to disasters which must be carried out through legal discovery by judges which require a long and long time and mechanism. First, in Law Number 24 of 2007 concerning Disaster Management there are also several criminal provisions and the imposition of fines, both for individuals and legal entities, namely in Articles 75 to 79.

The essence of the penalties of this law are high risk, which is not equipped with disaster risk analysis, b) deliberately hampers easy access during a disaster emergency, and c) deliberately misuses the management of disaster relief resources. Thus, this Disaster Management Law also cannot be used as a reference in enforcing the Covid-19 health protocol as a non-natural disaster in the form of an outbreak. Second, Law of the Republic of Indonesia Number 4 of 1984 concerning Outbreaks of Communicable Diseases which in Article 14 paragraph (1) regulates "punishment for a person who deliberately obstructs the implementation of epidemic

control, shall be punished with a maximum imprisonment 1 (one) year and/or a maximum fine of Rp. 1,000,000.00 (one million rupiah). "This verse is categorized as evil. Article paragraph (2) stipulates "whoever because of his/her negligence causes obstruction of the implementation of the prevention of the epidemic, shall be punished with a maximum imprisonment of 6 (six) months and/or a maximum fine of Rp. 500,000.00 (five hundred thousand rupiahs."

This paragraph is categorized as a form of offense. What is meant by efforts to contain an infectious disease outbreak? Government Regulation of the Republic of Indonesia Number 40 of 1991 concerning Prevention of Communicable Disease Outbreaks in Article 10 states that "Efforts to contain epidemics include epidemiological investigations, examinations, treatment, treatment and isolation of sufferers, including quarantine measures, prevention and immunity, eradication of disease causes, handling of corpses. due to the epidemic, public outreach, and other prevention efforts. "Can the word "prevention" in this article legally be applied to those who do not wear masks while traveling outside the home? Or when holding a wedding party? In the explanation of number 13 of Government Regulation Number 40 of 1991 concerning Outbreak Management, it is stated that "What is meant by prevention and immunization are efforts to prevent and immunity people and their environment so that they do not contract the disease. These activities can be done through vaccination, spraying, and others. "

Thus, regulations regarding prevention by wearing masks, washing hands, and maintaining a distance cannot be fined by this article. This is because this article by law does not directly regulate the obligation to wear a mask and maintain a distance. A violation rule cannot be imposed on them without a clear legal basis regulating it in the law. Third, Law Number 23 Year 1992 concerning Health regulates criminal provisions in the terms of crime (Articles 80, 81, and 82) and offenses (Article 84).

Article 80 paragraph (1) regarding illegal medical actions, Article 82 concerning conducting illegal treatment and/or treatment, and illegal pharmaceutical actions, Article 84 crimes in circulating food and or drinks that are not marked or labeled and operating workplaces that do not meet standards, prevent people with mental disorders who will be treated and/or treated at health service facilities, from operating health facilities that do not meet the requirements. The Health Law also cannot be used as a basis for enforcement of health protocols during the Covid-19 pandemic. Fourth, Law of the Republic of Indonesia Number 6 of 2018 concerning Health Quarantine in which Article 93 regulates non-compliance with the administration of health quarantine and/or obstructs the administration of health quarantine so as to cause a public health emergency to be punished with imprisonment of up to 1 (one) year and/or a maximum fine of Rp 100,000,000.00 (one hundred million rupiah).

Fifth, Perpu No.1/2020 which regulates the issue of health impacts on the economy. Supposedly, the government should not only contain financial matters for handling health, economic impacts, and social safety net, but also regulate legal matters of health protocol enforcement. Because there is no positive law regulating the enforcement of health protocols (wearing masks, washing hands and keeping your distance) which does not have legal certainty and based on the principle of legality, **first,** the government and its law enforcement officers are only able to enforce health protocols with social sanctions, not law. like singing clean the way to read the Koran.[12-14]

Second, the State, in this case represented by the President, still considers that the legal rules regarding the prevention of infectious disease outbreaks are not yet available in articles in the legal regulations that contain health protocols and cannot be implemented. This is evidenced by the issuance of Presidential Instruction Number 6 of 2020 concerning Increasing Discipline and Law Enforcement of Health Protocols in the Prevention and Control of Covid-19 which was issued on August 4, 2020 which aims to provide legal certainty and encourage regions to issue regional head regulations that contain legal sanctions.

Violations of Health Protocols: Third, there is a legal polemic in enforcing health protocols regarding which articles are most appropriate to be used in apprehending health protocol violators, as we will discuss in the case of Habib Rizieq Shihab, the High Imam of the Isla Defenders Front. Fourth, law enforcement changes to a political discourse so that health protocol enforcement is in an area where there is no legal certainty so that the authority is unclear between the central and regional governments. Contrary to the Legal Hierakis to provide legal certainty in enforcing health protocols legally, President Joko Widodo issued Presidential Instruction Number 6 of 2020 concerning Increasing Discipline and Law Enforcement of Health Protocols in the Prevention

and Control of Covid-19 as an effort to enforce the law by providing sanctions in the form of legal fines on August 4, 2020. In the first dictum the presidential instruction (inpres) stipulates that, "The Ministers of the Advanced Indonesian Cabinet, the Cabinet Secretary, the Commander of the Indonesian National Army, the Chief of the Indonesian National Police, the heads of non-ministerial government agencies, the governors and regents/mayors take steps -the steps needed are in accordance with their respective duties, functions and authorities in ensuring legal certainty, strengthening efforts and increasing the effectiveness of the prevention and control of Coronavirus Disease 2019 (Covid-I9) in all provinces and districts/cities in Indonesia. "This Presidential Instruction also instructs regional heads to issue regional head regulations to contain sanctions in the form of: verbal warning or written warning, social work, administrative fines, or termination or temporary closure of business operations, whereas from the legal hierarchy point of view, regional head regulations are not justified. loading sanctions.

In the second dictum point 6 letter b of the presidential instruction, it states that the governor/regent/ mayor drafts a governor regulation or regent/mayor regulation by including sanctions for violations of the Covid-19 Protocol committed by individuals, business actors, managers, organizers, or person in charge of public places and facilities. This Presidential Instruction includes a legal flaw in terms of both the legal hierarchy and the regulated material. First, the Inpres is not part of the hierarchy of legislation in Indonesia, but is part of what Ishviati Joenaini Koenti says is a complement to the principle of legality and is a form of discretion. This is due to the limitations and weaknesses of written law, namely: it is impossible for the law to be complete because of the complexity of society's problems and written regulations are static. Discretion is something that cannot be avoided, both for the application of law itself and in the implementation of government.[15]

Presidential Instruction Number 6 of 2020 contradicts Article 7 paragraph (1) of Law Number 15 of 2019 concerning Amendments to Law Number 12 of 2011 which has regulated the hierarchy of statutory regulations, in which presidential instructions and governor regulations, as well as regent regulations/ mayor is not included in the hierarchy of the laws and regulations of the Republic of Indonesia. Second, based on this instruction, the Indonesian government issued regional head regulations, one of which is what the Aceh Government implemented by issuing Aceh Governor Regulation Number 51 of 2020 concerning Improved Handling of Coronavirus Disease 2019 Implementation of Discipline and Law Enforcement of Health Protocols in Aceh on 7 September 2020. [16]

The regulation of the legal material for sanctions in the head regulation is contrary to Article 15 paragraph (1) which states that the contents of the criminal provisions can only be contained in: a. Constitution; b. provincial regional regulations; or c. district/city regional regulations. Meanwhile, the Presidential Instruction and Aceh Governor Regulations, as well as regent/ mayor regulations are not laws and are not regional regulations and are contrary to Article 15 paragraph (3) which states that provincial regional regulations and district/city regional regulations can contain the threat of imprisonment or imprisonment. criminal fine. Regulations by governors and regents/mayors are not legal products that are justified in imposing sanctions in any form.

"The statutory regulations in the Republic of Indonesia consist of: a) The 1945 Constitution of the Republic of Indonesia, b) Decrees of the People's Consultative Assembly, c) Laws/government regulations in lieu of laws, d) Government regulations, e) Presidential regulations, f) Provincial regulations, and g) District/city regulations. "Whereas Article 14 of the law states, "the material contained in Provincial Regulations and Regency/City Regulations contains material in the framework of implementing regional autonomy and co-administration, as well as accommodating special regional conditions and/or further elaboration of higher laws and regulations. "Regarding crimes, Article 15 paragraph (1) states that "The contents of criminal provisions can only be contained in 1) Laws, 2) Provincial Regulations, 3) Regency/City Regulations." The criminal threat is "imprisonment for a maximum of 6 (six) months or a maximum fine of Rp.50,000,000.00 (fifty million rupiah)." Paragraph (2) regulates, "Provincial Regulations and Regency/City Regulations may contain the threat of imprisonment or fines other than those stipulated in other statutory regulations." However, the Presidential Instruction and the Aceh Governor Regulation are not laws, nor are they provincial regulations and district/city regional regulations, but are merely instructions and governor regulations that cannot contain sanctions.[17,18]

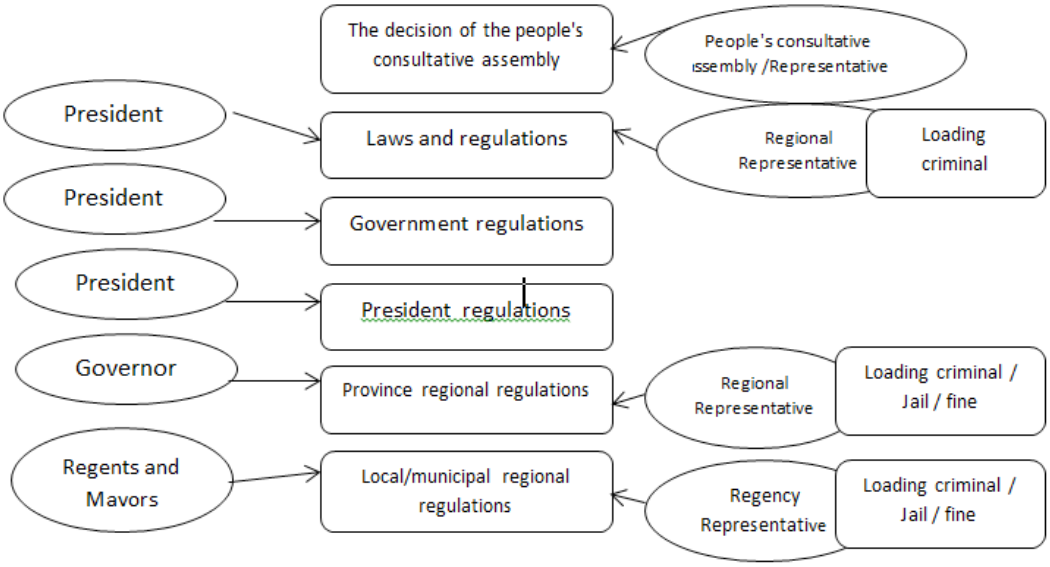

Figure 1. Hierarchical Indonesian Legislations

In Indonesia, a hierarchy of regulations has been regulated even though normatively it also adheres to unwritten customary law, but most legal cases decided by official Indonesian courts are based on written legal regulations issued or issued by state institutions. This means that Indonesia strictly adheres to the principle of legality, that is, all legal decisions based on regulations issued by government agencies in accordance with the authorities granted by law. The principle of legality is applied in criminal law.[19]

Article 1 paragraph (1) of the Criminal Code affirms that an act cannot be punished, except based on the strength of the existing criminal legislation. Anselm Von Feuerbach called it the principle of legality with the adage Nullumdelictumnullapoenasinepravialegepoenali. The principle of legality actually exists in the realm of State Administrative Law, which is a principle in which every administrative act must be based on law, both in making regulations and in stipulating and enforcing them. Indonesia strictly adheres to the principle of legality, that is, all legal decisions based on regulations issued by government agencies[20].

The law demands legality, what is required is the implementation and obedience or the actions that are required on an obligatory basis. There are two principles that must be adhered to in the legal system, especially those that contain sanctions against society. First, the principle of legal certainty and the principle of legal legality, as well as the principle of democracy. Any imposition on the community must be carried out with valid legal rules, the rules of which are discussed jointly between the executive and legislative branches, both at the level of the formation of laws, as well as the formation of provincial and district/city regional regulations[21].

Crowd Disbandment One of the weaknesses of the Indonesian Government in deciding the spread of Covid-19 is the uncontrolled crowd. This is because first, the concept of generality in the Covid-19 context is different from the concept of generality as regulated in the Criminal Code. Second, the legal concept in the Criminal Code crowd was not prepared for the concept of generality in the Covid-19 context. Third, many health protocol settings are regulated in the minister of health regulations which are not part of the structure of positive sources of law in Indonesia. What differentiates the crowd in the Covid-19 context from the crowd in the Criminal Code? What is clear is that the generality in the Criminal Code is planned, structured and there are political elements in society voicing their interests (common interests of groups), while the concept of crowds in the Covid-19 context is spontaneous, uncoordinated and just a coincidence. Examples of crowd demonstrations and crowds of people in public places such as to markets, stations and so on.[23]

Therefore the Chief of Police of the Republic of Indonesia tried to attract and provide a legal definition so that the crowd in the Criminal Code can be interpreted as a crowd in the context of terminating the spread of

Covid-19. The announcement of the Chief of Police of the Republic of Indonesia Number: Mak/2/III/2020 concerning Compliance with Government Policy in Handling the Spread of the Corona Virus contains the first, "the principle of people's safety is the highest law (Solus Populi Suprema Lex Esto)", second, "do not hold social activities social gatherings that lead to mass gathering in large numbers, both in public places and in their own environment, such as 1) social, cultural, religious and religious gatherings in the form of seminars, workshops, gatherings, and other similar activities; 2) activities of music concerts, fairs, festivals, bazaars, night markets, exhibitions and family reception; 3) sports activities, arts and entertainment services; 4) demonstrations, parades, carnivals; and 5) other activities that bring together the masses.

"This announcement also provides another bias to the public that in "urgent circumstances it cannot be avoided, activities that involve many people are carried out by maintaining a constant distance and must follow government procedures related to preventing the spread of Covid-19." This announcement is published on March 19, 2020. When crowds are allowed in Pilkada, the government has taken two different policies, even though one party crowd is protected by law, but when it applies during a pandemic, the crowd should not be enforced even with strict health protocols, because in fact every crowd in Indonesia health protocols are always being violated, especially wearing a mask and keeping your distance. This edict also cannot be used as a reference for positive law for two reasons. First, the announcement of the Chief of Police of the Republic of Indonesia is not positive law in the statutory system which is the basis of legal law in Indonesia. This regulation is only binding for the internal police, which is usually used to set internal operational standards for the police. Second, in content, the proclamation reopens the opportunity that crowds can be exercised for reasons of unavoidable interest, by not providing a legal definition of any "unavoidable circumstances".

Meanwhile, crowd dispersal has been regulated in Article 218 of the Criminal Code (KUHP), but it is not used optimally by the police because this article has multiple interpretations and is indeed formed to control crowds related to demonstrations and is political in nature, and the legal sanctions are only dissolution only. First, the use of Articles 212, 216, and 218 of the Criminal Code which can be used as an ultimatum remedium in enforcing health protocol laws. Article 212 of this law states that "Anyone with violence or threats of violence against an official who is carrying out a legitimate task, or who according to statutory obligations or at the request of the official to provide assistance to him, is threatened for fighting an official, with imprisonment. a maximum of one year and four months or a maximum fine of four thousand five hundred rupiahs. "

This article cannot be used as a basis for enforcement of the health protocol law, considering that this article contains elements of "violence" or "threats of violence" with the intention of "fighting" an "official" or "person providing help". Meanwhile, not wearing a mask, not keeping your distance is not an act of threatening violence or not fulfilling the elements of the article. Although legal discovery efforts can be carried out, such discovery activities in the criminal law system must adhere to the principle of legality. Article 216 paragraph (1) stipulates; "Anyone who deliberately does not obey orders or requests made according to law by an official whose job is to supervise something, or by an official based on his duties, as well as those who are authorized to investigate or examine a criminal act; Likewise, any person who deliberately prevents, obstructs or thwarts action to enforce the provisions of the law by one of these officials, shall be punished by a maximum imprisonment of four months and two weeks or a maximum fine of nine thousand rupiahs. (2) Equal to the aforementioned criminal, any person who according to the provisions of law has been continuously or temporarily assigned the task of carrying out a public office."

This article also cannot be used as a basis for fines and penalties, considering that there must be an "order" or "request" which must also be based on law. As is well known, there is not a single article in the law in Indonesia that contains articles that are clear about wearing masks, washing hands and keeping your distance. Article 218 stipulates, "Anyone who, when the people arrive in a crowd, deliberately does not leave immediately after being ordered three times by or on behalf of the competent authority, is threatened with participating in a grouping by a maximum imprisonment of four months and two weeks or a maximum fine of nine thousand. Rupiah".

Article 218 also cannot be used as an attempt to convict a person or group of people who are gathering because it is not a crowd dealing with demonstrations or the like, but crowds because the factors of the epidemic are very different. Crowds like this are very common

in crowded centers. On what basis can the police use this article? In positive law in Indonesia, the matter of this crowd can be found in Article 216 and Article 218 of the Criminal Code. Article 216 paragraph (1) reads, "Whoever deliberately does not comply with orders or requests made according to law by an official whose job is to supervise something, or by an official based on his duties, as well as those who are authorized to investigate or examine a criminal act; Likewise, any person who deliberately prevents, obstructs or thwarts action to enforce the provisions of the law by one of these officials, shall be punished by a maximum imprisonment of four months and two weeks or a maximum fine of nine thousand rupiahs.[23]

Whereas Article 218 of the Criminal Code states, "Anyone who when the people come together deliberately does not leave immediately after being ordered three times by or on behalf of the competent authority, is threatened for participating in a grouping with a maximum imprisonment of four months and two weeks or a maximum fine nine thousand rupiah. "This article requires a long enforcement and trial mechanism in the Indonesian legal system and this article is aimed at crowds who are about to hold a demonstration using a mechanism that has been stipulated by law, especially Law Number 9 of 2008 concerning Freedom to Express Opinions in Public. This article was used to charge 27 workers with peaceful expression of opinions on October 30, 2015, on charges of "disrespecting the orders of the authorities recognized by law, namely police officers" and "not dissolving themselves after being warned three times by police officers. "So that on that basis the police officers forcibly dispersed and arrested 23 protesters and three lawyers/assistant public lawyers for LBH Jakarta.[24]

Second, many policies (discretion) are published, but in the Indonesian legal system discretion is not part of a legal product in the hierarchy of the statutory order. One of these discretions is the Minister of Home Affairs Regulation Number, Instruction of the Minister of Home Affairs No. 6 of 2020, Enforcement of the Health Protocol to Control the Spread of Covid-19 which contains the threat of removing regional heads in violation of the law[25].

This Imendagri letter also caused polemics in the community about the power of law. Third, the legal uncertainty of the program has caused the handling of the crowd during the Covid-19 period to have no legal certainty for its implementation. Fourth, there are differences in legal definitions between the crowd in the context of the law of freedom of expression and the crowd which is not in the context of freedom of opinion such as weddings, commemoration of the Prophet's birthday, and so on. Then, the Minister of Home Affairs also issued the Minister of Home Affairs Instruction No. 6/2020 on the Enforcement of Health Protocols to Control the Spread of Covid-19 which contained the threat of removing regional heads in violation of the law. This Imendagri letter also caused polemics in the community about the power of law. The polemic surrounding the Imendagri is not included in Indonesia's positive law, with the first reason that the process of dismissing regional heads is in accordance with statutory regulations, especially the Regional Government Law (UUPD), regional heads are elected by the people and determined by the General Election Commission (KPU) and the president have no right to refuse. Dismissal must be through the DPRD with an impeachment mechanism until the opportunity to defend oneself to the Supreme Court. Second, based on Law Number 15 of 2019 concerning the Compilation of Legislation, the Presidential Instruction is no longer included as a form of legislation. This is to put an end to doubts about the status of the Inpres that were very much published during President Soeharto.

This inability to apply sanctions and fines resulted in massive demonstrations during the pandemic such as the Omnibus Law demonstration of the Job Creation Act and finally RizieqShihab which resulted in the Head of the Jakarta and Banten Special Capital Region Police being removed from his position and this case has caused polemic laws ranging from criminalizing clerics, violating health protocols violating the Health Law, then Rizieq was detained under other legal regulations that have nothing to do with violating the Covid-19 health protocol but relating to incitement and fighting against the authorities. Finally, there was a shooting which killed six of Rizieq's bodyguards[26-31].

Conclusion

Positive law that exists in Indonesia, there are no specific articles that can be applied to enforce health protocols (wearing masks, washing hands, keeping distance, and not crowding) so that implementation has created legal uncertainty and is not in accordance with the principle of legality, and tends to enter in a political versus legal interpretation. The Indonesian government is aware of the legal vacuum and the existence of legal uncertainty which results in the enforcement of health

protocols into legal polemic and has not been able to become a legal instrument with coercive power to suppress the positive number of Covid-19. The legal vacuum was then addressed by the central government by issuing Presidential Instruction Number 6 of 2020 which essentially wanted to provide legal certainty in terms of enforcing health protocols and the Instruction of the Minister of Home Affairs Number 6 of 2020 dated 18 November 2020, which essentially contained a threat to regional heads who violated laws and regulations can be dismissed. However, enforcement of health protocols remains a legal polemic, in other words, enforcement does not meet the requirements and legal certainty.

The Minister of Home Affairs has issued Circular Number 440/31660 dated May 15, 2020, which in its third point asks regional heads to prepare regional regulations that contain health protocols. As of November 2020, only DKI Jakarta has made it a regional regulation. There are several solutions that can be taken in solving this problem of legal certainty and so that there is a definite law enforcement. First, in the short term, the Government of Indonesia must immediately issue government regulations in lieu of laws (perppu) for the benefit of systematically enforcing health protocols so that health protocol enforcement has certainty, both material and formal laws, and law enforcement is certain, namely the police, prosecutors., and judiciary (court). Much must be regulated in the Government Regulation in Lieu of a Law, such as the use of Covid-19 patient data by the police, Second, for the short term, the governor and regent/mayor immediately propose to the parliament so that the governor regulations and regent/mayor regulations can be made into regional regulations/qanuns so that they have legal certainty in the imposition of fines and other sanctions.

Third, for the long term, the authority to determine disaster emergency status by governors, regents and mayors needs to be expanded, with the governors and regents/mayors being authorized to issue governor/regent/mayor regulations in lieu of regional regulations. This is analogous to the authority of the president, but governors and regents/mayors are given limits on their authority, namely only for disaster regulations, especially in imposing imprisonment and fines on residents who violate health protocols. Even the Chinese Government, which has tended to rely on the control of the communist political party since the last five years, especially under Xi Jinping, has developed the principle of legal legality, namely a very legalistic way, empowering courts, emphasizing legal professionalism, in other words the principle of legality where no punishment can be imposed, unless there is positive law in writing regulating it. In other words, the Chinese authorities make more use of organizational capacity and legal legitimacy rather than circumventing the legal system.

Abstract

The majority of sports organizations including gymnastics in Central Java Province still use school arenas which are quite small and not representative according to the rules of the Federation Internationale de Gymnastics (FIG). Meanwhile, athletes must train without the hindrance of external factors such as our facilities. Purpose of Study: To provide a solution that can be applied to a limited school area by conducting field analysis and designing a suitable model, especially for uneven rods in gymnastics. The material in this study is the school arena, the uneven bars. Observation and measurement are used to collect data, then analyze it using Computer Aided Design software. The data are presented as descriptive quantitative. Result: To facilitate uneven trunks it can be constructed using either a log or glass fiber with adjustable posts (lower: 1.61-1.70 meters; upper: 2.41-2.50 meters), and with grip properties such as tension: 13.64 Newton, displacement: 1.17 mm, strain: 4.428 m/m. Conclusion: The modified unmodified bar has been designed to optimize training sessions in a limited school area.

Keywords: *Sports technique, elite sports, gymnastics.*

Introduction

Sport is a human physical activity, now it has become a necessity of life. As an activity that involves large muscles, sport can be used as a tool in meeting economic needs, maintaining fitness and rehabilitation, as a means of recreation, education, and of course achievement. Sports can be grouped into three areas, namely; educational sports, recreational sports, and achievement sports[1]. However, there is about the scope of this sport, as stated in the excerpt of the paper Sport Science in Indonesia, namely; physical education, health sports, competitive sports (sports), recreational sports, and dance. Of the various types of artistic gymnastics equipment requires a good construction design, because the equipment is expected not to change the position of the tool so that the gymnast's movement technique during training and during competition does not change according to the assessment criteria[2]. For that in the use of training equipment for artistic gymnastics, requires the arrangement of mechanical installations is performance sports equipment, especially in gymnastics, both during training and for competition requires constant equipment conditions[3]. To help the calculation of constant equipment levels, one of them is by using CAD software (Computer Aided Design), because it is part of a multidisciplinary study between sports and engineering or what is called sports engineering. Likewise the need for sport engineering in artistic gymnastics based on the request of the Code of Points for various types of cutting-edge techniques[4]. The connotations of sport engineering are diverse, comprehensive and balanced. It is an extension of the latest techniques that must also adhere to this principle. To support the study of sports engineering in determining the conceptual design of building construction and sports equipment that can support the achievement of high-performance and sustainable sports facilities and infrastructure[5]. Based on the results of interviews with researchers with officials of the Central Java PersaniProv, of 35 existing Persani District and City Administrators, the use of gymnastic

training facilities on single and multilevel bars in Central Java has not been effective, because based on average data the tools used are using modification tools. and it is not yet known the level of constancy in these tools using CAD (Computer Aeded Design). In addition, the main Persani organization in Central Java uses a school hall building as a gymnastic training place with a limited size of the school hall building, so that the arrangement of the facilities on single crossbar and multi-storey bars cannot be installed in the building because these tools use stakes to installation, so that it requires a large enough space, the parent organization Persani which uses modified equipment installed outside the room from 6 main organizations consisting of Grobogan, Karanganyar, Pati, Pemalang, Rembang and Temanggung districts[6].

The equipment modified by the 6 parent organizations of different shapes and sizes, both from material specifications and operational use of multilevel cross bars, cannot be adapted to the needs of athletes, while the 25 main gymnastics organizations in Central Java do not have single crossbar and multilevel cross bars. This results in not running the training program because the equipment is installed outside the room so that external factors are disturbed, one of which is the weather. On the other hand, the price of one of the standard FIG gymnastics products for the AAI brand on the single crossbar reaches $ 3,450 or around Rp. 48,300,000, -, while in the JannsenFritsen multilevel crossbar tool $ 6,216 or around Rp. 87,024,000, -. The price of the equipment is not included in the cost of shipping and taxes, so that the procurement of gym equipment for single crossbar and multilevel bar with standard specifications at the regional level cannot be fulfilled because the price of the equipment can be said to be expensive and cannot be installed in a limited space because it requires land. which is quite extensive. To solve this problem, the researcher feels the need to conduct development research so that existing problems can be immediately resolved and the results of research in the form of a model product development of a multipurpose training tool for artistic gymnastics in the form of a modified single-bar and multilevel crossbar without using a stake that can be used on Limited training space and can be used as an alternative to training by gymnastics athletes and for coaching the parent organization Persani in Central Java. Through the model of developing a multi-purpose training tool for artistic gymnastics on a single crossbar and a multilevel bar, this can provide solutions to overcome the efforts to improve skills in the aspects of motion related to the composition of requirements in assessment during competition, as well as the composition of requirements on single crossbar and multilevel bars referring to in Code of Points Artistic Gymnastics 2017-2020[7]. The development of a multipurpose training tool for artistic gymnastics on a single crossbar and a multilevel crossbar is hoped to be able to overcome the limitations of facilities and infrastructure to increase the level of effectiveness, efficiency and usefulness in the use and installation of artistic gymnastics equipment for motion training on single-bars and multilevel bars, assuming it can be used. installed in a space that is limited in size without the use of a rope staple and the level of constancy of the tool can be seen with CAD (Computer Aeded Design) software[7].

Based on the description above, the researcher needs to conduct research on the development of a multipurpose training tool for artistic gymnastics based on CAD (Computer Aeded Design) [8]. The hope is that the product development model for a multipurpose training tool for artistic gymnastics that researchers will develop can be owned by each parent organization Persani in Central Java. at a very affordable price because the tool is designed with two tools into one tool called the development of a multipurpose training tool for artistic gymnastics on a single crossbar and a multilevel bar. So that the parent organization can carry out an exercise program programmed and can be a boost for coaches, athletes and the parent organization of the gymnastics branch as a means of training and training activities in Central Java. The purpose of this development is to produce a product for the development of a multipurpose training tool for artistic gymnastics as an alternative as a means of exercise through several steps, namely:

1. Developing a multipurpose training tool for artistic gymnastics on a single bar and a multilevel bar as needed and can be used with minimal facilities.
2. Developing a multipurpose training tool for artistic gymnastics on single-bar and multi-tiered bars which are effective for installation in limited building spaces.
3. The results of the model for developing a multipurpose training tool for artistic gymnastics can be accepted by trainers and athletes in Central Java.

Method

Development research is research that aims to produce and develop a product in the form of a prototype. Research is to solve practical problems in gymnastics coaching in Central Java, the problems faced by athletes and coaches in implementing training programs, researchers are not for testing theories, testing hypotheses, or testing and perfecting products[11]. Research and development, usually called research-based development, is a type of research that is being increasingly used in solving practical problems in the world of research, especially educational research and learning. Research and development is a process used to develop or validate products used in learning education. Furthermore, it is stated that the research and development procedure basically consists of two main objectives, namely: (1) developing the product, and (2) testing the effectiveness of the product in achieving the goal. In this research, the development model used is a procedural development model, because this model is descriptive, which is a procedure that outlines the steps that must be followed in producing a product[12]. In each development can choose and find the most appropriate steps for research based on the conditions and constraints faced[13]. Define development research as a systematic assessment of design, development and learning programs, processes and products that must meet the criteria of validity, practicality and effectiveness[14]. The criteria "can show the added value of the three criteria. Research and development is a process used to develop or validate products used in education and learning. The development procedure carried out in designing, creating and evaluating (validation) in this study, using outcome measures adapted from Borg & Gall [15]

The trial was carried out to get responses and product revisions, so that the final product would be produced in the form of a development model for a multi-purpose training tool for artistic gymnastics on a single crossbar and a multilevel crossbar according to the needs of the athlete. The trials were carried out in small group trials and field trials. In this study, the trial design used was experimental design. Product development trials go through two stages, namely small group trials and field trials. The test subjects or respondents involved in this research are the parent organization PERSANI in Central Java which is divided into two stages consisting of small-scale trials and trials. field. The small-scale trials in this study included three parent organizations including Pati, Rembang and Grobogan districts with 12 athletes, with details of each district consisting of 4 athletes. While the large-scale trial covers 7 regions in Central Java. The data used in this study are qualitative data. Qualitative data obtained from interviews in the form of criticism, suggestions from gymnastics experts and resource persons orally and in writing as constructive input for product revision materials. The instruments used to collect data in this study were observations, interviews, questionnaires, field observations and documentation. Questionnaires are used to collect information in a systematic and targeted manner from experts and resource persons. Meanwhile, questionnaires and field observations were used to determine the feasibility and acceptability of the product. The validity of the data is an important thing in research, because it is a guarantee of confidence in solving the problems being studied[16]. To determine the validity (trustworthiness) of data, an examination technique is needed. The implementation of inspection techniques is based on a number of certain criteria. There are four criteria used, namely the degree of trust (credibility), transferability (transferability), dependability (dependability), and certain (comfirmability). In order for the data obtained to have a guarantee of trust, in this study the researcher used the criteria for the degree of trust (credibility). The author uses three data credibility checking techniques, namely triangulation, member checking, and peer discussion. Triangulation in credibility is defined as checking data from various ways, and various times. Thus there is triangulation of sources, triangulation of data collection techniques and triangulation of time. This research uses triangulation of sources and triangulation of data collection techniques[17]. Checking members by showing data or information, including the results of the researchers' interpretations that have been written in the format of field notes or interview transcripts to other information deemed necessary. Comments, reactions or additional information data were used to revise field notes or interview transcripts. The data analysis technique used is the percentage to analyze and the assessment of the developer's subject in assessing the feasibility, effectiveness and acceptability of the product to the development product. Respondents will be interpreted by the results they get, namely providing the results of tests that have been carried out. The data obtained through the testing activities were clarified, namely qualitative data. Qualitative data in the form of criticism of suggestions put forward by gymnastics experts and athletes are then collected for improvement.

Result and Discussion

Based on the results of the survey that has been carried out, in the use of single crossbar and multilevel gymnastic tools in Central Java, the model of the tool used is still using a stake as a training facility, so that the tool cannot be installed in the building because it requires a large enough area. The parent gymnastics organization in Central Java does not yet have a multipurpose training tool for artistic gymnastics on a single bar and a multilevel bar as a training facility that can be installed in a limited size building space. The trainer cannot carry out the training program on the single crossbar and multilevel bar in the rainy season, so the athlete cannot do exercises to improve the movement skills on the single-bar and multilevel crossbar effectiveness in carrying out training programs and utilizing hall space as training infrastructure, it can be said that logically the choice of development of a multi-purpose training tool for artistic gymnastics is made on single-bar and multilevel bars. Based on a glimpse of the conditions described in the previous chapter, it is hoped that the development of single-beam and multi-tiered bars can run better. Trainers and athletes do not only do exercises outside the building but can develop the exercise process to be more creative and innovative, so that they can accommodate the activities needed by artistic gymnastics athletes based on understanding the rules on the aspect of the composition of requirements in the code of points artistic gymnastics. Gymnastics new 2D models of single bars including end point movements[18]. 2D modeling of single crossbar apparatus in men's gymnastics is reviewed. Parameter estimation is described regarding two problems, first, to determine the measurement demands posed by parameter estimation, and second, to find the need for new parameter estimation due to different single bars in the review. It is then used to evaluate the adequacy of the FIG (Federation Internationale de Gymnastique) requirements for high competitive standards. The model structure is developed and justified, using two different sets of single bars. Static and kinematic measurements show very different stiffness, damping and inertia characteristics in the vertical and horizontal directions, which is due to the spatial non-fixation of the end points of the horizontal bars, as they attach to the vertical posts connected to the floor. Horizontally, the end-point motion was found to add 30% to the measured motion of the bending of the rod, while vertically, the end-point motion was hardly measurable at all. Hence the two directions are modeled differently. Horizontally, two damped linear springs connected in series are attached to the measurement data, whereas vertically only one spring is required, demanding a total of nine stiffness, damping and effective mass parameters for the model. It appears that only the parameter ratios are required to model the forced rod oscillations and that all nine parameters can be found from three parameter measurements, i.e. stiffness, and then curve fitting into a single cross bar self-oscillation in two directions to find the remaining. The parameter variation appears to be significant between the bars and finally, the adequacy of the FIG vertical stiffness requirements was found to be questionable.

The sports building design has a huge impact on top sports. This implies challenging tasks to meet performance requirements, including such as daylight/ lighting factors, air conditions. Such factors have an impact on athlete performance and are difficult to control in large sports halls; their control is even more difficult when the public/audience is in a hall and requires different climatic conditions. While mechanical installations are often required during competitions to ensure constant conditions, conveying mechanical installations during daily and recreational use of the venue challenges medium or long term sustainability. A computational form-seeking approach can support the achievement of high-performance and sustainable sports buildings. In this regard, this paper discusses the use of multi-objective and multidisciplinary design optimization. This paper presents the concept of multidisciplinary and multi-objective design optimization techniques to support the trade-off decision between several conflicting design objectives and interdisciplinary design methodologies, during the conceptual design of sports buildings[19]. From the various sources of literature review above, a model for developing a multipurpose training tool for artistic gymnastics can be developed as an alternative to exercise which can increase the level of effectiveness, efficiency and usefulness in motion training on single and multilevel bars, assuming it can be installed in space. which size is limited without using a rope staple. Of the various types of gymnastics available, the following is a specification for a single crossbar and a multilevel bar which will be used as a reference by researchers in this development research, including the following:

Single Cross: The single crossbar is one of the six numbers of tools in the sport of gymnastics in men's art. The regulations set by the International Federation of Gymnastics (FIG) rods are made of stainless steel 2.4m long and 28mm in diameter, while a single bar is 2.50

m high over a mat with a thickness of 20 cm and is held in position by two supports which are stabilized by four stakes [20]

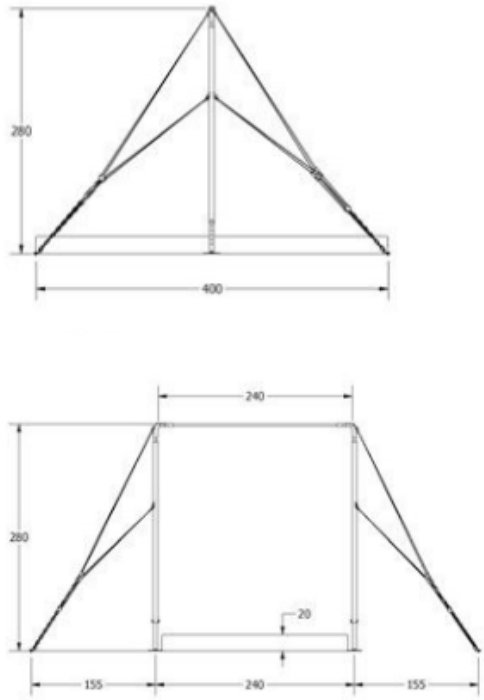

Figure 1. Single Cross

In a single crossbar, several types of motion aspects in the composition of requirements that refer to the code of points must be carried out by the gymnast which includes the giant swing, the skills of releasing, turning and changing direction, by using the momentum of the giant swing movement and sufficient height to be reached for dismounting.

Multilevel Cross: The multi-storey crossbar consists of two logs or fiberglass, each resting on a vertical support pole of different heights. The lower bar is 1.61 m to 1.70 m from the floor, while the upper beam is 2.41 m to 2 m., 50 m.

On a multilevel crossbar, the gymnast navigates two horizontal handles at different heights and a predetermined width, the gymnast performs swinging, turning, transitioning and releasing movements during the movement of the multilevel crossbar grip and ending with a dismount motion. The presentation of the exercise on a single crossbar and a multilevel bar must pay attention to the following matters: (1) The gymnast must start his training by doing kip which is an initial step performed by the gymnast. Motion assessment begins when the gymnast moves to kip on the handle of a single bar or a graduated bar. (2) The gymnast must enter the composition of requirements in the code of points artistic gymnastics which is carried out by the gymnast with full safety and with a high degree of aesthetic and technical mastery according to the ability of their respective athletes. It is hoped that this single and multilevel bar can also improve the movement skills of the tool. With the development of a multipurpose training tool for artistic gymnastics on a single crossbar and a multilevel bar, it is hoped that athletes, coaches and coaches will be more active in making various training models, so that through the development model of developing multipurpose training tools for artistic gymnastics on single bars and bars multilevel can be increased and can create various kinds of model development tools that can be used with minimal facilities and can improve the skills of athletes in accordance with the expected goals. The product model developed by the researcher as an alternative training facility in the form of a multipurpose training tool for artistic gymnastics is based on a needs analysis and existing equipment specifications, namely the AAI brand for single bars and the Gymnova brand for multilevel bars.

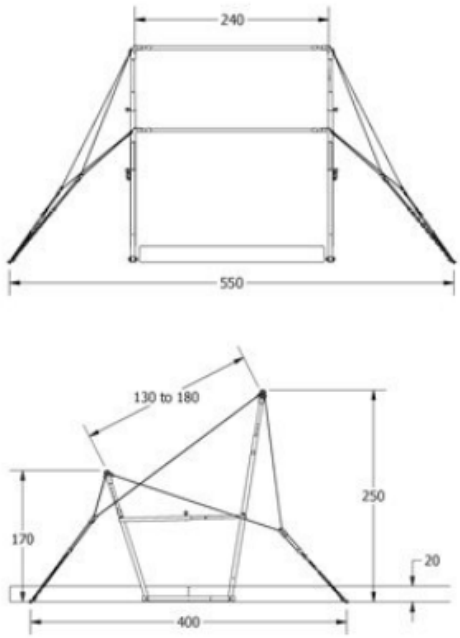

Figure 2. Multilevel Cross

The product specifications for the development of a multipurpose training tool for artistic gymnastics developed by researchers can be seen in the table below: Table 1. Specifications for the development of a multi-purpose training tool for artistic gymnastics on the single-bar and multilevel bars.

No.	Standard Tools	Tools developed
1		
2		

Figure 3. The design of the multilevel crossbeam tool

The image above is an initial design as a tool design that will be developed by the researcher, assuming the tool can be used for single crossbar and multilevel bars with an alternate use model, this is a design to accommodate the size of the hall which is limited in size, so that the design of the tool is designed to be used multipurpose and at the same time to overcome the limited size of the existing hall, with the specifications of the materials used as follows:

Figure 4. Design of the single crossbar tool

Table 6. Material Specifications for the Development of Multipurpose Training Tools for Artistic Gymnastics

No	Material	*Uneven Bars* Standard	*Uneven Bars* Developed
1	High support pole pipe diameter	5,5 cm	62 cm
2	Plate press thickness diameter	6 mm	6 mm
3	The length of the base construction of the press	1,2 m	2 m
4	The width of the basic construction plate press	-	2,54 m
5	Pipe quill diameter	4,3 cm	5 cm
6	Stabilizer Pipe	4,3 cm	
7	High bar height	2,45 up to 2,5 m	2,45 up to 2,5 m
8	Low bar height	1,5 m up to 1,70 m	1,5 m up to 1,70 m
9	Handle diameter of uneven bars	4,1 cm	4,1 cm
10	Stabilizer cable diameter	5,5 mm	Do not use stabilizer cables

With the development of a multipurpose training tool for artistic gymnastics on a single crossbar and a multilevel bar, athletes can do exercises when it rains, because these tools can be installed in buildings without using stakes which require a large area. Optimized kip performance on single bar. The characteristics of a simple goal-directed task, such as a grabbing hand gesture, have been well studied from the perspective of optimization principles. However, it remains unclear what characteristics or control mechanisms of these movements are shared with the movements more generally, (Yamasaki, Gotoh, & Xin, 2010). This paper focuses on gymnastic maneuvers on a single bar, referred to as a kip movement. The kip movements of the expert gymnasts are represented only by the three-link planar model, and attempt to be reproduced under three optimization criteria: the minimum angle criterion; reported minimum torque change criteria to describe multiple joint reach motion; and minimum effort criteria. Numerical analysis shows that 1. there is no criterion which considers that only the starting and ending points can reproduce the measured movements of the gymnast; however, 2. the minimum torque change criterion which assumes a starting and ending point, and the corresponding points can almost reproduce the measured motion, which is the best predictor of the three criteria with the way-point. The results may indicate that the reach of the hand and certain parts of the kip motion share a general characteristic roughly explained by the minimum torque change criterion.

Effect of optimization constraint on multilevel crossbar on dismount swing simulation in the research of Sheets AL and Hubbard M. Simulation of forward motion dynamics of multilevel crossbar on dismount swing preparation is optimized for observing errors in multilevel crossbar grip before dropping at dismount. Optimization constraints are classified as 1-anatomical/ physiological; limiting the maximum hand strength on the crossbar grip before dismount, maximum joint range of motion and torque, muscle activation/deactivation time and 2 geometrics; avoids low-bar contact, and requires minimum landing distance. The gymnast model includes the torso/head, arm, and two leg segments connected by a loop, compliant shoulders, and a frictionless ball-and-socket hip joint. Maximum shoulder and hip torque is measured as a function of joint angle and angular velocity. Movement is driven by maximum torsion scaling with a joint torsion activation function of time that approaches the mean activation of all muscles crossing the joint causing extension/flexion, or adduction/abduction. The force bar accelerates the center of mass while doing muscle work to flex/lengthen the joints, and increase the gymnast's mechanical energy. The optimal technique for generating angular momentum in the giant rear is accelerated before dismounting (Hiley & Yeadon, 2003). In men's artistic gymnastics numbers, the rear giant on a single bar is used to generate the angular momentum needed for the gymnast to dismount in a rotating manner. Mounting from where the gymnast is performing two cartwheels in a layout position (straight body) requires the greatest angular momentum. However, there appear to be two different techniques used by elite gymnasts when performing a giant circle of retarded before the two-round layout while dismounting. The "traditional" techniques have been replaced by those currently used

by the majority of elite gymnasts. To determine whether the scooped technique is better at generating angular momentum, a simulation model is used to optimize the angular momentum about the center of mass when released. The model was evaluated using data obtained from the video force analysis of an accelerated giant. Two optimals were found that are characteristic of the two giant circle techniques used by elite gymnasts. The traditional technique generates more angular momentum than the scoop technique although both techniques are capable of generating sufficient angular momentum for a layout of multiple dismount rotation. As a consequence, elite gymnast preference for scooped technique should be based on factors other than angular momentum production[21].

Determination of the dynamic elastic modulus of polymer materials under high strain loads using the Hopkinson technique (SHPB) of pressure on a stratified crossbar[22]. The associated factors, namely, the influence of the pressure imbalance in the specimen, the indentation of the stratified bar due to the specimen and the slope between the specimen and the stratified bar, are widely studied. The study of the crossbar material shows that for specimens the size of the specific elastic modulus and diameter of the size is very important for the degree of influence in this study. However, polymers with low modulus of elasticity can still be measured accurately regardless of the curvature shown. Numerical investigations of the tilt effect show that imperfect contact conditions greatly affect the accuracy of the measured modulus of elasticity. This problem can be fixed by the newly proposed vertical SHPB. This can significantly improve the contact conditions between the rod and the specimen and offer an acceptable accurate measurement of the dynamic elastic modulus of the polymer material. Measurement of dynamic force on a single bar using 3D motion capture[23]. The calibrated single-bar displacement is used as a measure for the force acting on the single bar itself during a dynamic gymnast look in artistic gymnastics. A single bar is loaded with a known force and the displacement is observed using the Vicon motion observation system. The calibration results are installed according to EulerBernoulli's beam theory. After calibration, the force can be directly measured by multiplying the displacement of a single bar with the specified fit parameter. This approach can also take into account the application of non-central force (two hands on the handle of a single bar) and the effect of single-bar inertia. The uncertainty in the measured strength was assessed plus an additional 1% for the unknown weight distribution between the hands.

Conclusion

With the development of a multipurpose training tool for artistic gymnastics on a single crossbar and a multilevel crossbar, athletes can exercise when it rains, because these tools can be installed in buildings without using stakes which require a large area. Optimization of kip performance on the bars single .. Numerical analysis shows that 1 there is no criterion which considers only the starting and ending points that can reproduce the measured movements of the gymnast; however, 2. the minimum torque change criterion which assumes a starting and ending point, and the corresponding points can almost reproduce the measured motion, which is the best predictor of the three criteria with the way-point. The results may indicate that the reach of the hand and certain parts of the kip motion share a general characteristic roughly explained by the minimum torque change criterion. Optimization constraints are classified as 1-anatomical/physiological; limiting the maximum hand strength on the crossbar grip before dismount, maximum joint range of motion and torque, muscle activation/deactivation time and 2 geometries; avoids low-bar contact, and requires minimum landing distance. The gymnast model includes the torso/head, arm, and two leg segments connected by a loop, compliant shoulders, and a frictionless ball-and-socket hip joint. Maximum shoulder and hip torque is measured as a function of joint angle and angular velocity. Movement is driven by maximum torsion scaling with a joint torsion activation function of time that approaches the mean activation of all muscles crossing the joint causing extension/flexion, or adduction/abduction. The force bar accelerates the center of mass while doing muscle work to flex/lengthen the joints, and increase the gymnast's mechanical energy. Therefore, the stratified bar constraints and forces inherently limit the performance by limiting the ability to carry out movement and reducing the energy of the system when releasing the grip on the multilevel bars. The calibration results are fitted according to EulerBernoulli's beam theory. After calibration, the force can be directly measured by multiplying the displacement of a single bar with the specified fit parameter. This approach can also take into account the application of non-central force (two hands on the handle of a single bar) and the effect of single-bar inertia. The uncertainty in the measured strength was

assessed plus an additional 1% for the unknown weight distribution between the hands.

Management of Occupational Hygiene Therapy on the Ability to Perform Self-Care on Deficient Self-Care Patients Who are Cared for in RSKD, South Sulawesi Province

Syahrir[1], Fatmawati[2]

[1]*Lecturers of University of Islam Makassar, Indonesia*

Abstract

Occupational therapy is a therapy that directs a person to participate in carrying out certain tasks that have been given or assigned, occupational hygiene therapy forms a person to be independent, not dependent on the help of others. So that clients with self-care deficits can do ADL such as eating, dressing, grooming, defecating, and getting pregnant independently. This study aims to determine the effect of occupational hygiene therapy on the ability to perform self-care for deficient self-care patients who are treated at RSKD, South Sulawesi Province. This research is a quantitative research with a quasi-experimental approach with pre-post test one group test which was conducted at the Hospital of South Sulawesi Province. The sample size in this study was 10 respondents. Based on the results of the study, it was found that the effect of personal hygiene occupational therapy on the ability to perform self-care in patients with self-care deficits, the p value of bathing needs: 0.004, the need to dress and dress = 0.004, eating and drinking = 0.004 and defecation = 0.006 using the Wilcoxon rank test. Occupational therapy needs to be applied to self-care deficit clients because this therapy teaches the introduction of existing abilities in a person so that clients can return to independence.

Introduction

Mental health is a feeling of being healthy and happy and being able to overcome life's challenges, being able to accept other people as they are and having a positive attitude towards oneself and others 1. About 35 million people affected by depression, 60 million people with bipolar disorder, 21 million affected by schizophrenia, and 47.5 million affected by dementia[2,3]. In Indonesia, with a variety of biological, psychological and social factors with a diverse population, the number of cases of mental disorders continues to increase which has an impact on increasing the burden on the country and decreasing human productivity in the long term. Riskesdas 2018 data shows the prevalence of mental emotional disturbance which is indicated by symptoms of depression and anxiety for ages 15 and over reaching around 14 million people or 6% of the total population of Indonesia. Meanwhile, the prevalence of serious mental disorders, such as schizophrenia, reaches around 400,000 people or 1.7 per 1,000 population[3,4]. According to Riskesda in 2018, South Sulawesi was among the top five people with mental disorders after Aceh Province and the special area of Yogyakarta, the prevalence of mental disorders in South Sulawesi was 2.7 per thousand people with a female prevalence ratio of 7.4 compared to 4.5 for men. Mental disorders begin with unresolved stress, this condition is a physical and psychological reaction to any demands that cause tension and disrupt the stability of everyday life[5]. Continuous stress conditions will cause individuals to suffer from schizophrenia, which is a condition where there is a serious mental disorder characterized by decline in communication due to loss of contact with reality and deterioration in work functions, social relationships or self-care from the previous level [6.]

Group activity therapy is carried out in a group manner, where each participant must have the same problem. While occupational therapy can be carried out in groups and individually so that the therapist can provide intervention to therapy participants in detail according to the needs of the client compared to using group activity therapy[7]. The further rehabilitation process in patients who experience cognitive decline, the inability to interpret stimuli so that reactions to stimuli are unnatural and who are easier to express feelings through activities and who are easier to understand the learning process in direct practice should be done individually[8].

Materials and Method

This type of research is a quasi-experimental quantitative study with a one group pretest posttest design approach carried out in RSKD South Sulawesi Province with a sample size of 10 respondents who were taken using purposive sampling method.

Results

In this study using the Wilcoxon Runk Test with a significance level of α = 0.01 this is because the observation data is not normally distributed which is determined by looking at the Shapiro-Wilk value of 0,000 so it does not meet the requirements for using the t test, if the p-value is obtained smaller than the α value, p <a = 0.01 then Ho is rejected or Ha is accepted. If the p-value obtained is greater than the value of α p> a = 0.01, then Ho is accepted or Ha is rejected. From the results of data processing carried out, it is presented in the form of demographic data on the characteristics of the respondents as follows:

Table 1. Distribution of the frequency of respondents based on education for deficient self-care patients who are treated at the Regional Special Hospital of South Sulawesi Province in 2020

Education Level	n	%
Basic	5	50.0
Junior high school	3	30.0
Senior high school	2	20.0
Total	**10**	**100.0**

From Table 1, it shows that the frequency of education of the most respondents was at the elementary level of education as many as 5 (50.0%) respondents and the least was in the high school education group as many as 2 (20.0%) respondents.

Table 2. Frequency distribution of respondents based on age in patients with deficit self-care who are treated in the ylang room at the Regional Special Hospital of South Sulawesi Province in 2020

Age	n	%
Early mature	3	30,0
Elder mature	6	60,0
Adult	1	10,0
Total	**10**	**100.0**

From Table 2, it shows that the age frequency of the most respondents is in late adulthood as many as 6 (60.0%) of respondents and the least in the early adolescent age group is 1 (10.0%) of respondents.

Table 3. Frequency distribution of respondents based on length of stay in clients with self-care deficits in the ylang room at the South Sulawesi Provincial Special Hospital in 2020

Length of stay	n	%
1 month	6	60,0
2 month	3	30,0
3 month	1	10,0
Total	**10**	**100.0**

From Table 3, it shows that the frequency of length of stay of respondents at most is in the length of stay of 1 month as many as 6 (60.0%) of respondents and the least is the length of stay of 3 months as much as 1 (10.0%).

Table 4. Frequency distribution of respondents based on the need for bathing before intervention in clients with self-care deficits in the ylang room at the Regional Special Hospital of South Sulawesi Province in 2020

Need for bathing before intervention	n	%
Fully assisted	7	70.0
Partially assisted	3	30.0
Total	**10**	**100.0**

From Table 4. The frequency distribution of respondents based on the need for bathing before the intervention in clients with self-care deficits in the cananga room of the Regional Special Hospital of South Sulawesi Province, showed that respondents who were less fortunate based on the need for bathing that were partially assisted were 3 (30.0%) of respondents and those who needed to be helpeda total of 7 (70.0%) respondents.

Table 5. Frequency distribution of respondents based on the need for bathing after intervention in clients with self-care deficits in the ylang room at the South Sulawesi Provincial Special Hospital in 2020

Need for bathing before intervention	n	%
Partially assisted	2	20,0
Self	8	80,0
Total	**10**	**100.0**

From Table 5. Frequency distribution of respondents based on the need for bathing after the intervention. In the self-care deficit in the ylang room at the Regional Special Hospital of South Sulawesi Province, it shows that respondents who need bathing are partially assisted by 2 (20.0%) of respondents and those who need a bath who are able to independently as many as 8 (80.0%) respondents.

Table 6. Frequency distribution of respondents based on the need to dress and dress before the intervention in clients with self-care deficits in the Kenanga room at the Regional Special Hospital of South Sulawesi Province in 2020

The need to dress and dress before the intervention	n	%
Fully assisted	8	80,0
Partially assisted	2	20.0
Total	**10**	**100.0**

From Table 6, the frequency distribution of respondents based on the need to dress up and dress before the intervention for clients with self-care deficits in the cananga room of the Regional Special Hospital of South Sulawesi Province shows that respondents who are based on the need to dress and dress assisted by a total of 8 (80.0%) respondents and Partially assisted were 2 (20.0%) respondents.

Table 7. Frequency distribution of respondents based on the need to dress and dress after the intervention in clients with self-care deficits in the ylang room at the Regional Special Hospital of South Sulawesi Province in 2020

Dress up and dress after intervention	n	%
Partially assisted	5	50,0%
Self	5	50,0%
Total	**10**	**100.0**

From Table 7, the frequency distribution of respondents based on the need to dress up and dress after intervention in clients with self-care deficits in the ylang room of the South Sulawesi Provincial Special Hospital in 2018 shows that respondents who need to dress and dress are partially assisted and who are able to be independent as many as 5 (50, 0%) of respondents.

Discussion

Needs a Shower: From the frequency distribution of respondents based on the need for bathing before the intervention to deficient clients of self-care in the Kenanga Room at the Special Regional Hospital of South Sulawesi Province, it shows that respondents who are less fortunate based on the need for bathing who are partially assisted are 3 (30.0%) respondents. From the data, it was found that respondents were not able to apply bathing twice a day in the morning and evening, and were unable to brush their teeth at least 2 times a day. Meanwhile, respondents with the need for bathing were assisted by 7 (70.0%) respondents. From the data obtained, the client was unable to apply the need for bathing 2 times a day, using shampoo, and the client was also unable to brush their teeth at least 2 times a day.

The client's inability is because some clients are patients with social problems with social isolation so that the client is lazy to do activities, the client just lies on his bed so that other needs are not done. Clients need special guidance from officers to direct so that their needs can be met. From the frequency distribution of respondents based on the need for bathing after the intervention on self-care deficits in the cananga room of the Regional Special Hospital of South Sulawesi Province, it shows that respondents who need bathing are partially assisted by 2 (20.0%) respondents. This is because the data obtained by the client is not able to apply bathing 2 times a day, is not able to brush their teeth twice a day and is not able to prepare toiletries independently, so that respondents still need guidance in fulfilling their bathing needs. The inability of the respondent to apply a bath twice a day is supported by a feeling of laziness to take a bath, and the respondent feels that he does not need to take a shower in the afternoon because he does not have activities outside the room. In addition, the inadequate change of clothes available in the room makes patients lazy to take a shower because there are no changing clothes for the afternoon available after the patient has bathed.

Meanwhile, 8 (80.0%) respondents who need independent bathing have been able to take care of their bath needs, but there is one need that has not been able to be implemented, namely bathing 2 times a day in the morning and evening. Respondents only showered in the morning because they did not feel smelly and dirty. In addition, the unavailability of toiletries in the room such as soap, toothbrush, toothpaste, shampoo and towels makes patients lazy to take a shower in the afternoon. The condition of the fully closed bathroom makes it difficult for officers to guide patients in the bathroom as well as the number of bathrooms that do not match the number of patients so that it takes a long time to complete bathing activities for patients in the ward. While the client's toiletries are in the treatment room, this is because there are patients who cannot be oriented in terms of recognizing toiletries so it is dangerous if they are placed in the patient's room ward or in the bathroom. Based on the results of the study, it can be seen that schizophrenic clients who experience self-care deficits before doing activity therapy, the perception stimulation group is less able to perform personal hygiene care with an average value of 8.05. This is due to the lack of motivation given to clients regarding personal hygiene care to be done at any time so that clients think that personal hygiene care is not so important to him based on research conducted[9-12].

As a nurse, what you can do is discuss it with patients, check the needs of patient hygiene practices and provide accurate and adequate information to patients. This illustrates that the level of independence of the need for bathing after after occupational therapy with the partially assisted category has increased to the independent category, and overall assistance has increased to the partially assisted category. The increase in patient independence is due to the patient's concern for himself and because the patient's understanding of what has been taught by nurses and researchers so that it can be applied properly by patients. Needs to dress up and dress. From the frequency distribution of respondents based on the need to dress up and dress before the intervention, clients with self-care deficits in the recall room of the Regional Special Hospital of South Sulawesi Province, it shows that respondents who are based on the need to dress and dress assisted are 8 (80.0%) respondents.

The data obtained from respondents are not able to do the need to button and zip their own clothes and are unable to apply combing their hair, this is because the client is still confused, unable to remember and restore the abilities he had before he was sick so that clients need special guidance from nurses or officers in the room . Meanwhile, the respondents who needed some assistance were 2 (20.0%) respondents, the client was only able to choose and prepare the clothes to be used, the suitability of clothes for the time, and to use sandals if they were prepared. The client's inability to fulfill other needs is influenced by the client's awareness that he has not fully recovered so that the client still sometimes experiences disorientation towards reality, so that the client needs special guidance from the nurse or officer in the room to restore his basic abilities. From the frequency distribution of respondents based on the need to dress and dress after the intervention in clients with self-care deficits in the Kenanga Room at the Regional Special Hospital of South Sulawesi Province, it shows that respondents who need to dress and dress are assisted in part by 5 (50%) respondents, the data is obtained that the client has not able to choose and prepare clothes to be used, and not able to adjust the clothes to be used with the time of use.

The client's inability to orientate towards reality is still lacking even though the client has received special guidance from a nurse or officer in the room, this is due to the length of time the client has had mental disorders, so it requires a long time and continuous guidance during rehabilitation. There were 5 (50.0%) respondents who had been able to be independent, the data was obtained that overall they were able to make grooming and dressing needs, but there is one need that has not been able to be applied, namely the mismatch between the clothes you want to use and the time. The need for clothes at the hospital is provided in the same container between one patient and another patient with a sufficiently minimal number of clothes, so that the patient is clothed with shared clothes, making it difficult to assess the patient's independence in sorting and wearing clothes according to time. In the activity of implementing occupational therapy, the researcher prepares his own clothes with several kinds of clothes which are then chosen by the patient so that the researcher can assess the patient's independence in terms of dressing, for the purposes of dressing the client is also in the treatment room. the recognition of dress up tools so that they are dangerous if placed in the patient ward.

The results of this study are in line with research conducted by Prasetyo, 2018 concerning the application of personal hygiene occupational therapy in

schizophrenic patients with nursing problems with self-care deficits at the Menur Mental Hospital, Surabaya. In 6 days, the client was cooperative, the appearance was neat, the client looked confident, there was eye contact, theclient was able to self-care independently. So that the more frequent personal hygiene occupational therapy is done, the client will always be more accustomed to being independent in terms of self-care, especially in terms of appearance. 1. Needs to eat/drink From the frequency distribution of respondents based on the need to eat/drink before the intervention to clients with self-care deficits in the Kenanga room at the Regional Special Hospital of South Sulawesi Province, it shows that respondents who need to eat/drink who are assisted are 6 (60.0%) respondents from the data obtained by clients. unable to apply washing hands before eating and after foodand taking food from the container and putting it in the mouth. Loss of memory and confusion that is felt due to mental disorders experienced causes a reduction in the patient's basic abilities in small things such as feeding food into the mouth, so that when the patient eats, the patient's food is scattered. Meanwhile, 4 (40.0%) respondents were partially assisted, the client was only able to take the food that had been provided by himself, eat in the space provided, and be able to chew the food. The client's inability to implement other needs such as washing hands is due to only one wastapel in the room, so it requires a long queue to wash hands, this causes respondents to be lazy to wait for washing hands besides the habit patterns that have been implemented make respondents accustomed to eating without washing their hands first .

Independence is the ability or situation in which individuals are able to manage or overcome their own interests without depending on other people. The independence of an elderly person can be seen from the quality of life itself, where the quality of life can be assessed by the ability to carry out daily activities. The independence referred to in this study is the independence of patients in taking care of themselves such as eating, dressing, defecating/urinating, and bathing in reaction with fellow patients. Occupational therapy or occupational therapy is the science and art of directing one's participation to carry out certain predetermined tasks. This therapy focuses on the introduction of abilities that still exist in a person, maintenance and improvement aims to form a person to be independent, not dependent on the help of others. The purpose of occupational therapy is to restore mental function to create certain conditions so that clients can develop the ability to be able to relate to other people and the surrounding community, as well as restore physical function, increase movement, muscles, joints, and teach ADL such as eating, dressing, defecating and so on[14-19].

By giving directions to clients to help adjust themselves, improve their abilities, provide various activities for clients to try to find out their mental and physical abilities, habits, social skills, direct talents and hobbies to be used after the client returns to the community, it is hoped that the client can become more independent. This study explains that self-care occupational therapy has a positive impact on changing the client's ability to meet daily needs independently, this is because okupai therapy focuses on routine problems carried out by respondents in the form of directions that are carried out repeatedly so as to help clients change their behavior from being unable to become independent. However, the application of this therapy must be done repeatedly in terms of direct guidance to patients. The facilities that support the implementation of this activity greatly contribute to the development of the respondent's capacity. So that consideration of facilities is very important before doing therapy to patients.[19-21]

Conclusion

1. The results obtained prior to occupational therapy show that most of the respondents were assisted partly in terms of bathing needs and overall assistance in terms of grooming and dressing needs, food/drinking needs and defecation needs.
2. The results were obtained after occupational therapy, most of the respondents were able to be independent in terms of bathing needs and eating/drinking needs and most of them were partially assisted in dressing and dressing and defecation needs.
3. There is an effect of occupational hygiene therapy with the ability to perform self-care for deficient self-care patients who are treated at RSKD, South Sulawesi Province.

Abstract

The aim of this research is to explain the effect of massage effriction therapy and frirage therapy in helping creatine kinase levels in patients who have experienced injuries I and II with high and low stress levels. The method in this research is quasi-experimental with factorials. The treatments are effriction massage therapy and frirage massage. The two types of therapy that are used are a combination of the two massage method. Effriction massage is massage therapy that is dominated by efflurage and there is pressure to deep tissue. Frirage massage is a massage therapy that is dominated by the thumb and moves to grind but not deep due to scouring combined with efflurage. Both types of therapy are used in this study to obtain maximum results in lowering creatine kinase levels. Effriction therapy and frirage therapy were intervened with a duration of 15 minutes with the criteria for the sample who had level I and grade II injuries, and high and low stress levels. physical assessment test instruments for grade I and grade II injuries by looking at the results of the MRI lab, CT scan or by using a drower test. For the stress level, the instrument used is DASS to determine the level of stress. To measure creatine kinase levels by laboratory tests in collaboration with the pharmaceutical chemistry laboratory in Semarang. The conclusion of this study is that effriction massage therapy and frirage massage therapy can reduce creatine kinase so that it can be used for the therapy of grade I and grade II injuries, high and low stress levels, especially effriction massage therapy as a therapy that has better effectiveness than frirage in reducing creatine levels kinase for cases of knee injury, because one group in the effriction group experienced a significant reduction Keywords: Massage Therapy, Injury Level, Stress Level, Creatine Kinase Levels.

Introduction

Along with the development of this sport it has become a lifestyle that is not only practiced by professional athletes, but also by the general public. One of the sports is used as a means to improve and maintain body fitness. There are many types and alternative choices of sports that can be done by sports players, usually people exercise according to their hobbies and preferences for certain sports. By doing regular exercise, it can indeed nourish the brain[1]. This is due to the smooth circulation of oxygen flowing to the brain. The brain always produces new cells every time humans enter the growth and development phase. Since humans were born, their brains have never been the same and are always changing. When the brain is assigned different tasks, it will form new connections between brain cells. Synapses or junctions between two nerve cells will reconnect. Physical exercise involves the five human senses. That is why it can provide the brain with more information to integrate [2]. In addition, regular and controlled exercise can improve blood circulation, stimulate the dopamine hormone to increase its secretion so that the brain will get a signal to always feel good. Exercise is good for cardiovascular function which is good for the heart. A good heart will keep

the brain in good shape, because it reduces the risk of blockage so you avoid strokes, and increases energy use. A large increase in energy use with varying exercise doses will lead to physiological adaptations for the body with exercise records starting with low intensity to high intensity which are systematically programmed [3]. Physical exercise performed with high intensity and long enough duration can cause changes to occur at the cellular level[4]. Changes in the body in carrying out various kinds of metabolism will also produce various kinds of waste products, one of which is creatinine and is followed by an increase in the enzyme creatine kinase[5]. Creatine kinase is a molecular chemical enzyme produced from muscle metabolism, for creatine kinase tips. CK-M.Creatine kinase is transported through the bloodstream to the kidneys. Creatine kinase levels are determined by the amount of muscle mass (protein catabolism rate), in addition to how our body's metabolic activity, for example, increases when we are sick (heat/ infection) and triggers an increase in stress in the body, the increase in stress is in the form of metabolic stress or stress. mechanics. The stress that occurs in the body will trigger damage to muscle tissue structures and an inflammatory reaction. Damage to muscle tissue that occurs can cause an increase in serum creatine kinase (CK) levels and pain due to inflammatory reactions. The mechanism of increased creatine kinase is due to creatine produced during skeletal muscle contraction through the breakdown of creatinine phosphate [6]

Creatine kinase levels are predictors of biomarkers that are often studied to determine the degree of structural damage to muscle tissue. A person's creatine kinase activity can be influenced by age, gender, muscle mass, physical activity and weather or climate conditions[7].Total serum creatine kinase activity was recorded to have increased 24 hours after physical exercise and would decrease when athletes rest [8]. One of the important things that need attention in sports injuries is recovery for muscles that have damaged tissue or inflammation in the muscles[9]. The mechanisms that occur in the body after injury are the initial critical events in the inflammatory process that occur within hours of injury. The initial critical event in the inflammatory process is the accumulation of white blood cells, namely neutrophils, at the site of injury. Practical injuries based on their lightness can be divided into three parts, namely: (1) Level I injuries are injuries that are not followed by significant damage to body tissues, causing movement disorders in the recovery process, and The pain caused is negligible during activities and will heal on its own after a period of rest. (2) Level II injury is the level of tissue damage that is more significant, affects the athlete's performance, complaints can be in the form of pain, swelling, impaired function of signs of inflammation, for example muscle width, grade II muscle strain, sprain, tendons, torn ligaments (sprain grade). (3) Grade III (serious injury) is a serious injury, which is characterized by tissue damage in the body, for example torn muscles, ligaments or tendon breaks or fractures or fractures. Recovery is useful for giving the body the opportunity to adapt after an injury.Several method are used in an effort to speed up recovery in an injury, one of which is the first by stopping this exercise which is passive recovery, ice compresses are the first treatment when a new injury occurs. So it can be said that passive recovery is carried out at the beginning of an injury with the aim of maintaining performance, stabilizing acid-base balance, and reducing fatigue [10]. The next method is massage therapy which aims to be restorative for the injured. Before being treated by a professional when an acute inflammatory injury occurs, it is usually neglected and considered as no problem because the predicted level of injury is grade I and II. Even though the neglected injury actually makes the sufferer not free to do sports both in training and in competitions and sports injury sufferers experience stress [11]. after the 2x24 hour injury, it turns out that they do not experience optimal recovery so as to recover Injuries experienced by people engaging in sports require professional help[12].Professional treatment, one of which is massage therapy to restore the condition of the muscles, the injuries suffered are given treatment with massage therapy, repositioned and it is hoped that stress reduction will occur because the injuries experienced are handled properly to help the recovery process [13] The method used to provide massage treatment to injuries are few. In general the techniques used are efflurage, petrissage, tapotement, vibration techniques with a treatment duration of more than 15 minutes to reduce post-exercise pain. Not for injury recovery. For the treatment of injury, the technique used is a combination of existing techniques, namely the Swedish massage technique on the grounds that when providing treatment at least 2 combined techniques can provide time efficiency in trecillnent, so effriction and frirage techniques are selected[14].

The use of efriction was chosen because it is a combination of fluurageficiton in the implementation of the treatment, there is rubbing with the palms of

the hands, there is speed and massage pressure in the surface area that is being treated. Meanwhile, frirage is a combination of friction and efflurage, but the dominant treatment is the pressing of the thumb and there is no speed in rubbing the surface of the treated area. Frirage is a combination of massage techniques or manipulation of friction (scour) and effleurage (rubbing) which are carried out simultaneously in doing massage[15]. The hope of massage therapy that is carried out with the duration of treatment time is that athletes and sportsmen will not return to the same injury in the near future [16].Based on the facts in the field, it was found that the prevalence of injuries was 86% in sportsmen obtained in the preliminary study, and 73.5% of these injuries did not heal completely (Litbang KONI DIY, 2008). In some cases, injuries make a sportsman forced to retire early from the world of performance sports. Tennis player Angelique Wijaya is one example of a case of stopping a sports career due to an injury that did not heal completely. In America, approximately 20% of children and adolescents who participate in sports are injured each year. One in four cases of injury that occur is a serious injury (Konin, 2009). Massage therapy as a method of recovery is believed to be able to prevent muscle damage or wider tissue damage [17] .Massage interventions are carried out when the acute period of injury has passed, ie 3-6 days after injury . When the intervention was carried out, the response that occurred from the massage intervention was swelling of pain in the part that was receiving massage treatment, besides that there was also sties in the muscles. Although this therapy caused inflammation during massage therapy, after the intervention was carried out there was a change, namely a comfortable feeling marked by a decrease in pain when instructed to move the injured part and the wider ring of motion [18.]. Based on the above background and the research conducted by the researchers, there has been no research on the effect of massage on injuries that have a level of injury and experience stress that has been carried out in Indonesia, especially in sports players. Therefore, the researcher tries to find out how massage, injury level and stress level affect creatine kinase in sports players who experience injury[19].

Method

This study consisted of three kinds of factors or variables, which examined their effects on the dependent variable, namely the results of creatine kinase levels. The independent variables include the type of effriction and frirage therapy. While the attribute variable is the stress level, namely the level of injury I and II. Each independent variable has two levels, namely: 1) injury level: injury level I and II, 2) stress level: high and low category. This study used an experimental method with a factorial design. Therefore, the design in this study is a factorial experimental design in block design because the experimental units in the block are relatively homogeneous and the number of experimental units in a block is the same as the many treatments being studied. This study uses a 2 x 2 factorial design. x 2 because it consists of 3 independent variables and each independent variable consists of 2 levels[20]. Based on the literature review and the problems described above, the research hypothesis is as follows:

1. There is an effect of effriction therapy with injury level I with high stress levels on creatine kinase.
2. There is an effect of effriction therapy with level II injury with high stress levels on creatine kinase.
3. There is an effect of injury level I effriction therapy with low stress levels on creatine kinase.
4. There is an effect of effriction therapy with level II injury with a low stress level on creatine kinase.
5. There is an effect of Frirage Therapy with injury level I with high stress levels on creatine kinase.
6. There is an effect of Frirage Therapy with injury level II with high stress levels on creatine kinase.
7. There is an effect of frirage therapy with injury level II with high stress levels on creatine kinase.
8. There is an effect of frirage therapy with injury level II with high stress levels on creatine kinase.
9. There is an interaction of effriction massage therapy, frirage massage therapy at level I injury level and high stress level on creatine kinase level.
10. There is an interaction of effriction massage therapy, frirage massage therapy at level I injury level and low stress level on creatine kinase level.
11. There is an interaction of effriction massage therapy, frirage massage therapy at level II injury levels and high stress levels on creatine kinase levels
12. There is an interaction of effriction massage therapy, frirage massage therapy at level II injury levels and low stress levels on creatine kinase levels.

The population of this study were people who were active in sports or athletes who suffered injuries,

namely levels I and II, and who experienced low and high stress. The sample in this study were people who suffered injuries with homogeneous characteristics, namely injuries caused by sports activities, with almost the same level of injury, the attribute variable age was 18-35 years, male gender. The sampling technique was purposive sampling. The samples that had met the inclusion and exclusion requirements were 40 athletes. From this number, 40 are taken, then put into groups based on the criteria required by each group. Of these 40, a psychological test was carried out to determine the level of stress and to see the completeness of the required data, namely by bringing the CT scan or MRI or Xray results, the data stated that there was no broken ligament in the knee, if there was no supporting data for the athlete or athlete who was injured. performed a test with a drower test with the results that there was no shaking, no swelling was still stable but there was pain around the knee. There are 3 variables in this study, namely the independent variable that is manipulated, the attribute variable and the dependent variable. To avoid differences in the interpretation of terms on the variables contained in the study, it is necessary to describe the definitions of each variable in this study[21].

a. There are 2 independent variables that are manipulated, namely (a) In this. study, the independent variable (independent) consists of (1) massage therapy with the effriction and frirage method. This therapy method is intended as a therapeutic method that will be applied as an integral part of this research. The use of two therapeutic method using effriction and frirage therapy method is intended as a medium for different therapeutic programs to be grouped into research objects. (b) The form of the load is in the form of free weigth and machine weight.

b. The attribute variables in this study are Idan II injury level, and stress levels in the form of low and high stress levels. The intended stress level is the overall result of the selection of tests from athletes who have been selected as objects in this study.

c. The dependent variable in this study is creatine kinase

This level of stress can be measured by many scales. One of them is to use the Depression Anxiety Stress Scale 42 (DASS 42) or more which is summarized as the Depression Anxiety Stress Scale 21 (DASS 21) by Lovibond & Lovibond (1995). Psychometric Properties of The Depression Anxiety Stress Scale 42 (DASS) consists of 42 items and Depression Anxiety Stress Scale 21 consists of 21 items. The DASS is a 42-item questionnaire that includes three self-report scales designed to measure negative emotional states of depression, anxiety and stress. Each of the three scales contains 14 items, divided into subscales of 2-5 items with content equivalent ratings. The Depression Scale assesses dysphoria, hopelessness, devaluation of life, self-depreciation, lack of interest/involvement, anhedonia, and inertia[22]. The Anxiety Scale assesses autonomic arousal, skeletal muscle effects, situational anxiety, and subjective experiences affecting anxiety. The Stress Scale (item) sensitive to non-specific chronic levels of arousal. It assesses difficulty relaxing, nervous arousal, and irritability/restlessness, irritability/over-reactivity and impatience[23]. Respondents were asked to use a 4-point severity/frequency scale to rate the extent to which they had experienced each country during the past week. Where the research was conducted; 1) a sports injury massage therapy site, checking the level of injury, distributing a questionnaire to measure stress and taking blood samples at the Ngijo Sports Injury Massage clinic: the study population was taken from people who came for massage therapy at the Ngijo Sports Injury Massage therapy clinic who had a knee injury in 2019. To analyze the results of blood samples to determine serum creatine levels, it was carried out at Kimia Farma Semarang laboratory. The study began with a pre-test, in data collection starting in September and ending in December 2019 by conducting a direct post-test at one time when getting patients when getting patients from September to December and until the desired number of sample targets were met. Explanation of the research problem to the research subjects, then proceed with sampling by purposive sampling. Data was processed using SPSSversion 25 software. The difference in measurement results between before and after the intervention in the effriction massage therapy group and the frirage massage therapy group and analyzed using the paired t-test. Measurements after recovery between the effriction therapy group and the effriction massage group were analyzed using an independent t-test. The significance level was set at $p < 0.05$.

Result and Discussion

This study was conducted on 48 respondents who were divided into two groups of stress levels, namely high stress levels and low stress levels. Each implementation of massage therapy is always carried out

pre-test and post-test because the pres-test and post-tenst and massage interventions are given directly at one time. Respondents were verified as the target population when they had a therapy schedule, at the time of scheduling there was already a screening process so that someone who was injured would be the study sample. At the time of the study, researchers used sportsmen or athletes, it was expected that injuries were an effect of the sport they were doing. The results of this study were to look at serum creatine levels after massage therapy was carried out on athletes or athletes who had experienced Idan II level injuries and those with high stress and low stress. **Effect of Effriction Therapy with Injury Level I with High Stress on Creatine Kinase** Analysis of research data to determine the effect of effriction therapy with injury level I and high stress levels in this group with a total sample of 6 people who were given intervention in the form of effriction therapy for 15 minutes, the significance was 0.043. The test results are known to be smaller than 0.05 (0.043 <0.05) so that the hypothesis is accepted, meaning that there is a significant effect of massage effriction therapy on high level I injuries at high stress levels. From these results it can be interpreted that massage effriction therapy significantly reduces creatine levels in grade I injuries with high stress levels. Based on the data, the creatine kinase level in the first level injury group and the high stress level of the pre-test, all samples were in normal condition, namely the target of 130U/L, after being given the effriction massage therapy intervention, there was a decrease and in normal conditions, when analyzed by t test between pre test and There was a significant reduction in post test, meaning that massage effriction therapy helped the process of decreasing creatine kinase significantly in the injury level I group with high stress levels. Effriction massage therapy at the time of intervention even though it gives a painful effect at the time of massage therapy. In the section given effriction massage therapy intervention. So it can be concluded that massage effriction therapy can be given to patients who have level I injury and with high stress conditions

Effect of effriction therapy with injury grade II with high stress levels on creatine kinase.: Analysis of research data to determine the effect of effriction therapy with injury level II and high stress levels with the number of samples in the group with a sample size of 6 people who were given intervention in the form of effriction therapy for 15 minutes, that the significance was obtained 0.188. The test results are known to be greater than 0.05 (0.188> 0.05) so that the hypothesis is rejected, meaning that there is no significant effect of massage effriction therapy on level II injuries at high stress levels. The creatine kinase levels in this group were normal, i.e. they did not cross the reference limit for creatine kinase, but between the pre-test and post-test there was no increase or decrease in creatine kinase, even though at the time of massage effriction therapy intervention, there was a decrease in pain perception received by patients who were given therapeutic intervention.

Massaseeffriction, meaning that although there was no decrease in the creatine kinase pain received by the sample at the time of intervention was not part of the tissue damage at the time of injury, this was evidenced by the absence of an increase in creatine kinase levels in the blood at the time of the post test for the group with grade II injury and high stress levels. **Effect of injury rate I effriction therapy with low stress levels on creatine kinase** Analysis of research data to determine the effect of effriction therapy with injury level I and low stress levels in the group with a sample size of 6 people who were given intervention in the form of effriction therapy for 15 minutes, it was known that the significance was 0.061. The test results are known to be greater than 0.05 (0.061> 0.05) so the hypothesis is rejected, meaning that there is no significant effect of massage effriction therapy on high level I injuries at low stress levels. Effriction massage therapy that was intervened in the group with low stress level I injury did not experience a significant reduction in creatine kinase levels. This means that the creatine kinase level in the injury level I group and the low stress level under normal conditions, namely in the category in reference so that between the pre test and post test does not experience a significant decrease, if it is analyzed statistically, other influencing factors need to be studied in depthbecause it can it is assumed that with low stress levels in this group the kneeinjuries occurring are negligible and the likelihood of an increase in injury from grade I to grade II has a high potential. **Effect of effriction therapy with low stress level II injury to creatine kinase** Analysis of research data to determine the effect of effriction therapy with injury level II and low stress levels in the group with a sample size of 6 people who were given intervention in the form of effriction therapy for 15 minutes, the significance was 0.089. The test results are known to be greater than 0.05 (0.089> 0.05) so that the hypothesis is rejected, meaning that there is no significant effect of massage effriction therapy on high level II injuries at low stress levels. In the

effriction intervention group with injury level II and low stress levels there was also a decrease but not significant because in the pre test the creatine kinase level was obtained in normal conditions and after the intervention massage therapy, there was a decrease but not significant so that if analyzed there was no significant decrease in kratin levels. kinase. So that during the intervention process of massage effriction therapy, if there is pain during the intervention it can be assumed that the pain that arises is not due to inflammation in the muscle tissue or in the joints, so looking at creatine levels that are still in a normal state means that massage therapy can still be intervened even though it does not experience it. a significant reduction in creatine levels.

Effect of frirage therapy with injury level I with high stress levels on creatine kinase Analysis of research data to determine the effect of frirage therapy with injury level I and high stress levels in this group with a total sample of 6 people who were given intervention in the form of frirage therapy for 15 minutes, that the significance was 0.056. The test results are known to be smaller than 0.056 (0.056> 0.05) so that the hypothesis is rejected, meaning that there is no significant effect of frirage massage therapy on level I injuries at high stress levels. The creatine kinase level in the group that received the frirage massage therapy intervention did not decrease significantly, although it was not significant between the pre-test and post-test, the creatine kinase level in the reference group was in the normal category. The difference with effriction massage therapy, frirage massage therapy is only on the surface and takes a long time because based on observations of frirage massage therapy, according to the researcher, it is assumed that the technique is intended for parts of the body with a low level of muscle tissue thickness, such as the shoulder so that the creatine kinase level is decreased in the group. this is not optimal. **Effect of frirage therapy with injury grade II with high stress levels on creatine kinase** Analysis of research data to determine the effect of frirage therapy with injury levels II and high stress levels in the group with a sample size of 6 people who were given intervention in the form of frirage therapy for 15 minutes, that the significance was 0.188. The test results are known to be greater than 0.05 (0.188 <0.05) so that the hypothesis is rejected, meaning that there is no significant effect of frirage massage therapy on level II injuries at high stress levels. The creatine kinase levels in this group were normal, which did not exceed the creatine kinase reference limit, but between the pre-test and post-test there was no increase or decrease in creatine kinase, even though at the time of the frirage massage therapy intervention there was no pain perception received by the patient at the time of the intervention. Frirage massage therapy, because basically frirage massage therapy is only a rubbing that rubs and does not cause pain perception in patients who are treated with massage. This means that even though there is no decrease in creatine kinase and do not feel the pain received by the sample, there is no inflammation like during an injury during an acute condition, this is evidenced by the absence of an increase in creatine kinase levels in the blood at the time of the post test for the group with level injuries. II and high stress levels.

Effect of frirage therapy with injury level I with low stress levels on creatine kinase Analysis of research data to determine the effect of frirage therapy with injury level I and high stress levels in the group with a sample size of 6 people who were given intervention in the form of effriction therapy for 15 minutes, it was known that the significance was 0.079. The test results are known to be greater than 0.05 (0.079 <0.05) so that the hypothesis is rejected, meaning that there is no significant effect of frirage massage therapy on high level I injuries at low stress levels. The creatine kinase level in this group was normal, that is, it did not cross the reference limit for creatine kinase, but between the pre-test and post-test there was no increase or decrease in creatine kinase, even though at the time of the frirage massage therapy intervention there was no pain perception received by the patient at the time of the intervention. Frirage massage therapy, because basically frirage massage therapy is only a rubbing that rubs and does not cause the perception of pain in patients who are treated with massage. This means that even though there is no decrease in creatine kinase and do not feel the pain received by the sample, there is no inflammation like during an injury during an acute condition, this is evidenced by the absence of an increase in creatine kinase levels in the blood at the time of the post test for the group with level injury. I wish low stress levels.

Due to the possibility that in this group with low stress levels, it is assumed that the sample who suffered knee injuries ignored the injuries they experienced because during the activity it was not too disturbing and was considered to be able to recover on its own, it turned out that they did not immediately recover and eventually needed therapy to help the recovery process from the injury suffered. **Effect of Frirage Therapy with Low**

Level II Injury Stress on Creatine Kinase Analysis of research data to determine the effect of frirage therapy with injury level I and low stress levels in a group with a sample size of 6 people who were given intervention in the form of effriction therapy for 15 minutes, it is known that the significance is 0.091. The test results are known to be greater than 0.05 (0.091> 0.05) so that the hypothesis is rejected, meaning that there is no significant effect of frirage massage therapy on high level II injuries at low stress levels. In this group the intervention with frirage massage therapy with injury level II and low stress levels decreased but not significant because in the pre-test, creatine kinase levels were found in normal conditions and after intervention, frirage massage therapy decreased but not significant so that if analyzed there was no significant decrease. cratin kinase levels. So that when the interventional process of frirage massage therapy does not occur pain during the intervention, it can be assumed that there is no expansion of muscle tissue or ligament damage in the joints after the acute period, so looking at creatine levels that are still in a normal state means that massage therapy can still be intervened even though it has not decreased. creatine levels significantly. To determine the effectiveness of each intervention and to find out the difference in a significant reduction in the effect of the intervention, it can be seen in the following table:

Table 1 Factorial test of the effect of massage therapy, injury levels and stress levels on creatine kinase

Tests of Between-Subjects Effects					
Dependent Variable:Creatin_kinase					
Source	**Type III Sum of Squares**	**Df**	**Mean Square**	**F**	**Sig.**
Corrected Model	1307.250[a]	7	186.750	4.692	.001
Intercept	330.750	1	330.750	8.310	.006
JT	420.083	1	420.083	10.555	.002
TC	290.083	1	290.083	7.289	.010

Corrected Total	2899.250	47			
a. R Squared =,451 (Adjusted R Squared =,355)					

Based on the table of important values, it can be concluded as follows: The effect of all independent variables on the type of massage, level of injury, level of stress and levels of keratin kinase. The level of injury concurrently against the dependent variable (keratin kinase levels). If Significance (Sig.) <0.05 (Alfa) = Significant. Based on the table, the significance (Sig.) Of the Corrected Model shows 0.001 means that the model is valid independent, the dependent variable can change its value. If Significance (Sig.) <0.05 (Alfa) = Significant. Based on the Significance Table (Sig.) Of the Intercept, it shows 0.006 means that the Intercept is significant. The error value of the model, the smaller the model the better. The value of multiple determination of all independent variables with the dependent. Based on the R Squared Table shows 0.451 which is close to 1, which means strong influence.

Conclusion

The conclusion of this study is that effriction massage therapy and frirage massage therapy can reduce creatine kinase so that it can be used for the therapy of grade I and grade II injuries, high and low stress levels,

especially effriction massage therapy as a therapy that has better effectiveness than frirage in reducing creatine levels. kinase for knee injury cases, because one group in the effriction group experienced a significant reduction. The effect of all independent variables on the type of massage, level of injury, level of stress and levels of keratin kinase. The level of injury concurrently against the dependent variable (keratin kinase levels).

Detection of Anti-GAD65 Antibodies in Sera of Diabetic Patients Using a Home-Made Latex Agglutination Kit

Alaa S. Alattabi[1], Dhamiaa M. Hamza[1], Khalid Khalil Alaaraji[1], Sawsan M. Jabbar[1], Abeer Thaher Naji AL-Hasnawi[1], Ali Mansoor Jasim[1]

[1]Assist. Prof., Kerbala University, College of Medicine

Abstract

Objectives: Compare sensitivity of anti-GAD65 result detected by ELISA with that one detected by home-made latex agglutination kit.

Patients and Method: Thirty seven patients were enrolled in this study from January, 2019 to March, 2019. The sample had been taken from patients attended diabetic unit in Imam Hussain medical city in kerbala. Informed consent was taken from each participant in the study. Serum samples were tested by ELISA technique (GAD65 ELISA Kit, CUSABIO BIOTECH CO., LTD. USA) and by home-made latex agglutination for anti-GAD 65.

Results: Data from the current study showed that readings of the home-made latex test are consistent with those detected by ELISA as a confirmatory test. When analyzed, results showed sensitivity 94.44%specificity 78.95%, positive predictive value 80.95,negative predictive value 3.75%, positive likelihood 4.49, negative likelihood 0.07.

Conclusion: This home-made latex agglutination kit sensitive as ELISA could be used as a reliable test to detect anti GAD65 in diabetic patients.

Introduction

Diabetes mellitus is a long standing metabolic disorder due to insufficient insulin secretion or no response for insulin result in increased blood glucose level leading to multiple signs and symptoms[(1,2)]. From etiological aspect Diabetes mellitus divide into four classes, class 1 diabetes mellitus,class 2 diabetes mellitus,gestational diabetes and other class of diabetes. The most common classes of diabetes are class 1 and class 2[(3,4)]. Regarding class latent autoimmune diabetes in adult (LADA), clinically similar to class 2 diabetes but still has shared character with class 1 diabetes which has most autoantibodies present in class 1 diabetes[(5,6)]. Age of onset is commonly start after age of 35 years, at the beginning there is no need for insulin treatment[(7)]. The latent autoimmune diabetes in adult constitute around ten to thirty percent of classes 2 diabetes also refer as one and half class of diabetes or class 1.5 diabetes[(5,8)]. One of these antibody is **Glutamic acid decarboxylase autoantibodies (GADA)** which is neither beta cell nor islet specific, GADA firstly discovered in the serum of patients complaining from stiff man syndrome which is a rare neurological disorder[(9)]. In the neurons and pancreatic beta cells the glutamic acid convert to g-aminobutyric acid (GABA) by enzyme Glutamic Acid Decarboxylase[(10)]. Which can be measured to evaluate human disease[(11)] by different method like ELISA . Using latex particles coated with IgG is well known test currently applied for immunoassay investigation. In this study we compare sensitivity of GAD 65 result detected by ELISA with that one detected by home made latex agglutination kit.

Patients and Method:

Thirty seven patient were enrolled in this study from January, 2019 to March,2019 all patients were attended diabetic unit in Imam Hussain medical city Ethically, all consents from patients and kerbala health director had been taken .

Homemade latex agglutination test kit preparation:

A homemade latex agglutination test kit for the detection of anti-GAD 65 antibodies in serum was developed as follows:

1. **Latex beads preparation:** These were purified from a latex kit for testing C-reactive protein (CRP). Simply, the beads were separated from the CRP antibody by elevating the pH (up to 9) by adding 1 M NaOH solution to the latex-antibody complex of the CRP kit content. Thereafter, incubation for 1 hour at 37 ^{0} C was done. This was shown to be enough to unbind the antibody from the latex beads. In order to purify the beads, mixture was centrifuged 10000 Xg for 30 minutes. Then, we got a clear supernatant and a pellet of beads which were harvested by discarding the supernatant. This was followed by three times wash-spin step with PBS and the beads were suspended in PBS to be read ready to bind the new antibody.A test was done for CRP using the positive control of CRP kit content and the reading was negative. This step was done to ensure that no anti-CRP antibody remnant was left behind.
2. **Preparation of latex-antibody solution:** The detection antibody of anti-GAD 65 was ordered from (Abcam). Beads were mixed with the antibody (1 microgram/ml final conc.), pH was optimized at 7, and the mixture was incubated at 37^{0}C for 20 hours. After that, the mixture was ready for use as latex agglutination test reagent for the detection of anti-GAD 65 antibodies and stored at 4^{0}C. **[(**Hideki et al. 2000), with some modifications]$^{(12)}$.

Homemade latex agglutination test kit evaluation: A homemade latex agglutination test kit for serum detection of anti-GAD 65 antibodies was evaluated together with a commercially available enzyme-linked immunosorbent assay (ELISA) kit for their use for detection of anti-GAD 65. All patient serum samples were tested by ELISA technique (GAD65 ELISA Kit, CUSABIO BIOTECH CO.,LTD.USA) and by home-made latex agglutination for anti-GAD 65.

Statistical Analysis: To confirm the home-made latex kit results with those obtained by ELISA. Indicators like specificity, sensitivity, predictive values and likelihood determination were obtained when readings of both kits were analyzed using the biostatistic software Graph Pad Prism and Bayes Theorem Online Calculator.

Results

Data from the current study showed that readings of the home-made latex test are consistent with those detected by ELISA as a confirmatory test. Number of patients that showed positive anti-GAD65 result for latex technique were 21 of 37 patients while those positive GAD65 tested by ELISA technique were 18 of 37 patients as showed in table (1). Number of patients that showed positive serum for anti-GAD65 antibody by both technique latex and ELISA were 17 patients while those showed positive serum for anti-GAD 65 antibody by latex technique only and negative for ELISA were 4 patients and only one patients positive serum for anti-GAD 65antibody by ELISA technique only as showed in table (2) . Sensitivity 94.44%, specificity 78.95%, positive predictive value 80.95%, negative predictive value 93.75%, positive likelihood 4.49, negative likelihood 0.07, accuracy 86.49%.

Table (1): Seropositivity for Anti- GAD 65 antibody

Anti-GAD65 +ve by ELISA	Anti-GAD 65 -ve by ELISA	Anti-GAD65 +ve by latex	Anti-GAD65 -ve by latex
18	19	21	16

Table (2): Seropositivity for anti-GAD 65 antibody by latex and ELISA technique

	Latex+ve anti-GAD 65	Latex-ve GAD 65	P value
ELISA+ve GAD65	17	1	0.00001
ELISA-ve GAD 65	4	15	

	Latex+ve anti-GAD 65	Latex-ve GAD 65	P value
Sensitivity of latex/ELISA	94.44%		
Specificity	78.95%		
Positive likelihood ratio	4.49		
Negative likelihood ratio	0.07		
Positive predictive value	80.95		
Negative predictive value	93.75%		
Accuracy	86.49%		

Discussion

This homemade rapid latex test provide fast results, less expensive than ELISA and can easily be applied in routine laboratories in order to detect anti-GAD 65 antibodies thus facilitating the diagnosis of diabetes mellitus with a relatively high level of reliability

Conclusion

This home-made latex agglutination kit sensitive as ELISA could be used as a reliable test to detect anti GAD65 in diabetic patients.

Recommendation: It is highly recommended to follow this technique in order to prepare homemade latex agglutination test kits for the detection of other important diagnostic and prognostic markers in diabetes and even other clinical conditions.

Ethical Clearance: The Research Ethical Committee at scientific research by ethical approval of both environmental and health and higher education and scientific research ministries in Iraq

Effect of Polycythemia on Serum Lipid Profile and Oxidative Stress

Zainab Qasim[1], Muhammad Al-Yasiri[1]

[1]*Assistant Lect., Biology Department, College of Education for Girls, DhiQar University, Iraq*

Abstract

Polycythemia is generally known as a disorder that affects the stem cells in the bone marrow and is characterized by a high and excessive production of red blood cells. The current study was designed to investigate and investigate the relationship between the serum lipid profile and oxidative stress in polycythemia patients., The study included examining 85 blood samples from both gender, males and females, for patients coming to Shatra General Hospital. During the study period, all of (Hb, PCV, MDA, TC, TG, HDL, LDL, and VLDL) were examined for both patients and control groups.

The current study showed an increase in the incidence of polycythemia in males, while it decreased in females, and the study showed that the incidence of polycythemia increased with age until it reached its peak in the third age group 41-50 years, then the percentage gradually decreased to a minimum in the fifth age group 61-70 years .

The results of the study recorded a significant increase P <o.o5 in both the concentration of hemoglobin Hb and the packed cell volume PCV in patients with polycythemia, both real and secondary, when compared with the control group. Also, the results of the present study showed: a significant decrease P <0.05 in cholesterol concentration in the group of true polycythemia compared with the control group. A significant increase P <0.05 in concentration of triglycerides (TG) was higher in the true polycythemia group and a high significant P <0.05 in the secondary polycythemia group compared with the control group.

The results indicated that there was a significant decrease P <0.05 in LDL concentration in the true polycythemia group, and a significant increase of P <0.o5 in the secondary polycythemia group compared with the control group. The results of the study also recorded a high significant decrease P <0.05 in the true polycythemia group and a significant decrease P <0.o5 in the secondary polycythemia group compared to the control group. The results also showed a significant increase P <0.05 with the concentration of VLDL in the group of true polycythemia and high Significant p <0.05 in the secondary polycythemia group compared with the control group.

The results showed a significant increase P <0.05 in MDA concentration in polycythemia patients compared with the control group.

Keywords: *Polycythemia, lipid profile, oxidative stress.*

Introduction

Polycythemia: Polycythemia is generally defined as a disorder of the stem cells in the bone marrow characterized by the abnormally high and excessive production of red blood cells[(1)].

Polycythemia is a Greek term synonymous with Erythrocytosis,and literally translates to many cells in the blood[(2)]. Polycythemia is an uncommon clinical discovery, and one of its most important features is an increase in the number of red blood cells, as well as an increase in the concentration of hemoglobin (Hb) .and packed cell volume (PCV)[(3,4)].

Corresponding Author:
Zainab Qasim
Assistant Lect., Biology Department, College of Education for Girls, DhiQar University, Iraq
e-mail: ssarizvi06@gmail.com

Blood cells are formed by the process of erythropoiesis, and this process is controlled by the feedback mechanism, as erythropoiesis is inhibited when,the number of blood cells exceeds the normal limit, and the process stimulates when a decrease in the number of, red blood cells occurs as in anemia or in the case of lack of oxygen and this control depends on, the hormone Circulating in the blood called erythropoietin, which is secreted primarily by the kidneys, where the bone marrow receptors respond to it, stimulating the production of red blood cells in it, which soon leaves, it into the bloodstream to start its cycle and function in .the gas transport, and thus the red blood cell count in the blood remains,almost constant and the capacity of Transporting oxygen in the blood. is always sufficient for the body's needs, although,red blood cells are affected by many factors. such as age, gender, nutritional status, health status, and height above sea level[5]

Polycythemia is classified into two types:

1. **Relative Polycythemia:** The relative polycythemia has been called: (Pseudo-polycythemia) is a condition in which. an increase in the size of PCV cells occurs while the total mass of red blood cells (RCM) remains within normal limits. and this occurs as a result of fluid deficiency and dehydration that lead to :a decrease in blood plasma compared to; cells as in the case of dehydration, diarrhea, vomiting and use Diuretics, capillary leak syndrome,; and severe burns[6].

2. **Absolute polycythemia:** It means: the occurrence of a primary or secondary increase in. the proportion of the volume of packed cell volume PCV, and there is a real increase in the mass of red RCM [7]., and it is of two types:

A. **Primary polycythemia (Polycythemia Vera):** True polycythemia (PV) is due to intrinsic factors of red cell precursors and bone marrow with increased numbers of red blood cells, as well as leukocytes and platelets. The disease begins with a latent thrombotic stage .and is associated with an increased incidence of venous thromboembolism [1].

   It was found that there is a mutation that causes;true polycythemia vera disease, which occurs in a gene called (The Janus kinasez "JAK" 2),in exon 14 of chromosome 9, and this mutation was;discovered in approximately 95% of patients with .polycythemia vera and about 50% of people with Essential thrombocytosis and primary; myelofibrosis [2].

   There was no accurate understanding of these thrombotic tendencies and the level of hematocrit (PCV) was, the only laboratory factor that showed a clear association with thrombosis and; clinical symptoms to a large extent of increased erythropoiesis [3].

B. **Secondary polycythemia:** Erythropoietin; plays an essential role in controlling the production of red blood cells and .is under the influence of partial pressure of oxygen gas (PO2). This hormone;has a primary role in the excessive production of red blood cells (Polycythemia) by increasing the sensitivity of;the bone marrow to this hormone or An increase in its production by the cells; in the kidneys due to the increase in the, effectiveness of these cells, regardless of the partial pressure of oxygen, Secondary erythrocytosis occurs as a result of; some diseases such as congenital heart disease, chronic respiratory disease, smoking, and living at altitudes where. oxygen is lacking [1] . On the other hand, secondary polycythemia has a lower risk of blood clotting; despite higher hematocrit levels [4] .

   Polycythemia; can also increase blood viscosity, however there are no standard indicators of; the disease to predict vascular events. The oxidative stress that has been detected in many patients occurs due to an imbalance, between the generation of active oxygen species. and other free radicals and antioxidants, the blood becomes more viscous; and less able to flow through the blood vessels and organs of the body, and this slow, blood flow is responsible for much of Symptoms of this disease[2].

Aim of Study: In light of the above,, we decided to conduct the current study in order to investigate the effect of polycythemia on the serum. lipid profile and oxidative stress by studying. the following criteria:

1. Measuring. the serum lipid profile represented by CHO, TG, HDL, LDL and VLDL.
2. Measuring of. serum MDA as biomarker for the oxidative stress.
3. Measuring, the packed cell volume (PCV) ratio.
4. Measurement of hemoglobin Hb level in the blood..
5. Identify the largest infection rate .among different age groups.
6. Comparing the infection rate between the two, gender and investigating the causes.

Materials and Method

1. **Blood Samples:** Blood samples were, collected from Polycythemia patients during their visit, to Shatra General Hospital/Laboratory Unit. (85) samples, were obtained from these patients distributed between. two sexes during the research period, their ages ranged between (20 - 70) years., and they were examined in the hematology and biochemistry laboratories.;;

   For the period from November./2017 to June/.2018, when 5 ml of blood was taken for each sample., 2 ml of the blood sample drawn in a test tube containing an anticoagulant. were placed for them to be tested for hemoglobin (Hb). and the percentage. of packed cell volume (PCV) in the hematology laboratory, 3 ml were placed, in an anticoagulant-free test tube. Serum was obtained by placing these tubes in a centrifuge; at a speed of 3000 rpm for 15 minutes. The serum was separated from the. thrombus by a micro pipette. Serum was placed in the labeled Eppendorf tubes,. For the purpose of performing serum lipid profile (VLDL, LDL, HDL, TG, TC) and oxidative stress index .(MDA) tests, the same amount of blood was drawn from;healthy people (40) samples and the same tests were performed. for them for comparison purposes as they are control samples.

2. **Hemoglobin and PCV Measurement:** Hemoglobin and packed cell volume, (PCV) were measured using a blood tester Coulter Horiba The Emerald Company of French origin.

3. **Measurement of serum Lipid profile.**

   3-1. **Measurement of Total Cholesterol (TC):** The total cholesterol concentration was measured in the blood serum samples by using a colorimetric reflectance spectrophotometric method,.. according to the method of [8] . By following the in.,structions attached to the measuring. kit prepared by Randox - UK, which contains several solutions,. The concentration of, total cholesterol in the blood serum is measured after it has been oxidized and hydrolysed, by enzymes, as the index., quinonemine, consists of,hydrogen peroxide H2O2 and 4-aminoantipyrine in the presence, of phenol and peroxidase.. The amount of Quinonemine formed with a red pigment,gives the cholesterol concentration.

   3-2. **Measurement of Triglycerides (T.G):** The concentration of T.G was measured in the serum samples,by colorimetric reflectance spectrophotometry; according to the method[9]., by following the instructions attached. to the test kit for measuring the concentration of, T.G, imported from Randox UK, this kit contains several solutions, The principle. of measuring the concentration of T.G in serum is based on the hydrolysis of. enzymes to glycerol.

   3-3. **Measurement of High-density lipoprotein (HDL):** HDL concentration. was measured directlyin serum samples. by colorimetric reflectance spectrophotometry. by following the instructions attached to the. test kit for measuring, the concentration of. HDL, imported from Randox UK, this kit contains. many solutions and reagents.

   3-4. **Estimation of low-density lipoprotein (LDL) and very low-density lipoprotein (VLDL):** Its concentrations were calculated based on the Friedewald equation and according. to [10] as follows:

   LDL. = TC - (HDL+VLDL)

   VLDL, = TG/5

4. **Estimation oxidative stress:**

   4-1. **Malondialdehyde (MDA) assay:** The MDA concentration .(nmol/ml) in serum samples, for patients and control was measured .as biomarker for the oxidative stress, which is, Lipid Peroxidation Product. in human serum, it was determined by using the, method which described by [11].

5. **Determining the incidence of Polycythemia among males and females:**

   (Percentage of Polycythemia incidence)% =
   (Class number/The total number)*100

6. **Divide Polycythemia patients into five age groups:**

- The first age group. (20-30) years.
- The second age group, (31-40) years.
- The third age group, (41-50) years.
- The fourth age group, (51-60) years.
- The Fifth age group, (61-70) years.

7. **Statistical analysis:** Statistical data,analysis was performed on SPSS 17.0 to determine the mean, standard deviation., and other variables . *p* value less than 0.05 was considered statistically significant.

Results

Polycythemia relationship with gender: The current study showed an increase in the percentage of polycythemia infection. in males, which was 67.46%, while it decreased in females to 32.54%.

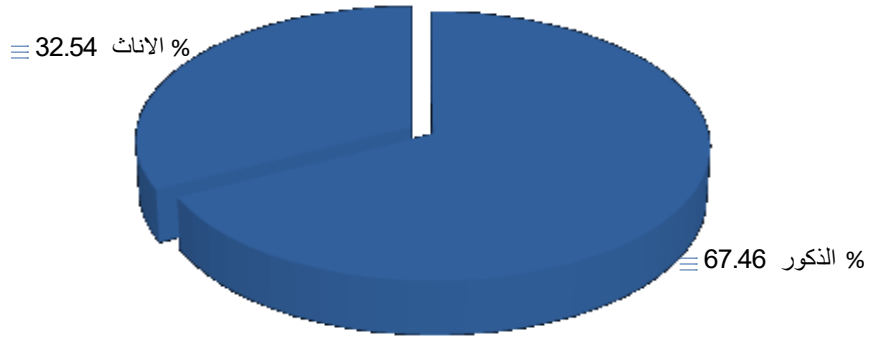

Figure 1: Polycythemiaincidence, depending on gender.

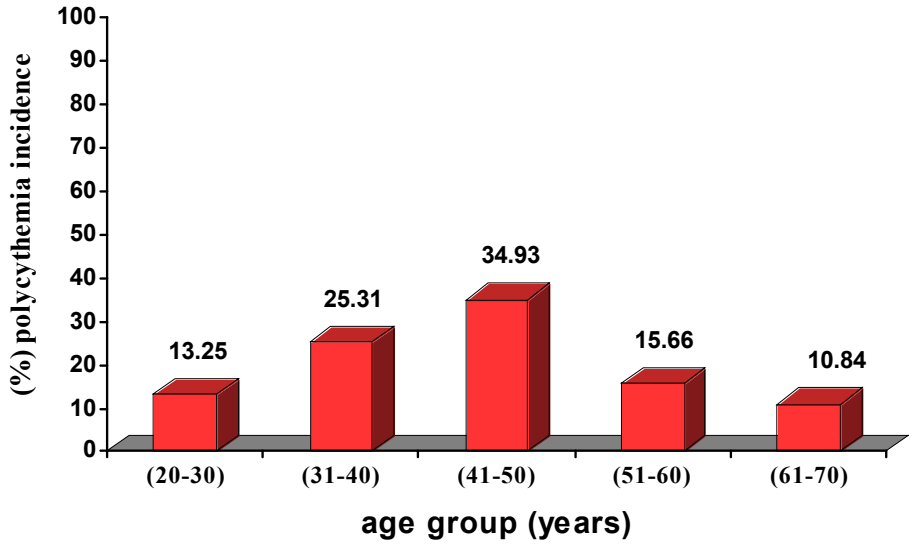

Figure 2: Distribution of age groups in polycythemia patients.

Polycythemia relationship with age: The current study showed,that the incidence of polycythemia .increased with age until it reached its peak in the third age group (41-50) years., and the rate was (34.93), then, the percentage gradually decreased to the lowest level, in the fifth age group (61-70) years,, and it was (10.84).

Effect of, polycythemia on concentration of hemoglobin and the PCV: The results of the current, study recorded a significant increase (P <0.05) in the hemoglobin concentration (Hb) in patients with true and secondary polycythemia,: PV group (2) and non-PV group (3), so the hemoglobin concentrations were. 17.48 ± 1.30, 17.15 ± 1.24 Respectively, compared to; the control group (1), where the Hb concentration was, 14.39 ± 1.06.

The results. also showed a significant increase (P <0.05) in (The packed cell volume (PCV) in patients. with true and secondary polycythemia, group (2) and group (3), so the PCV percentage, was 56.70 ± 2.42, 55.68 ± 2.32, respectively, compared with the control. Group (1), which amounted to 41.84 ± 1.61, as shown in Table (1) below.

Table (1): Effect of polycythemia on concentration of hemoglobin. and the PCV:

Studied Parameters Groups	Hb (g/dL)	PCV (%)	Number of samples
(1) Control group	14.39±1.06 [b]	41.84±1.61 [c]	40
(2) PV group	17.15±1.24 [a]	56.70±2.42 [a]	40
(3) Non- PV group	17.48±1.30 [a]	55.68±2.32 [b]	45
LSD	0.34	0.59	-

- The values represent the mean ± the standard deviation.
- The letters a, b, c indicate a significant difference (P <0.05) between the studied groups depending on the value of LSD.

Effect of polycythemia on serum Lipid profile: The, results of the current study showed through Table (2) that there was a significant decrease (P <0.05) in total cholesterol, TC concentration in group (2) it was 159.20 ± 22.59 compared; with the control group 193.02 ± 5.92, while the values of group (3) were 197.27 ± 15.96 An approach to a control (1).

The results; also recorded a significant increase (P <0.05) with the concentration of triglycerides TG in group (2) 148.59 ± 43.27 and a high, significant increase (P <0.05) in group (3) 179.56 ± 61.71 compared, to the control group (1) 119.83 ± 10.77.

The results indicated; a significant decrease (P <0.05) with LDL concentration in group (2) 92.45 ± 21.67 and a significant increase. (P <0.05) in group (3) 124.77 ± 44.52 compared; with the control group (1) 113.69 ± 27.76.

The results of the study,also recorded a high significant decrease (P <0.05) of HDL concentration in group (2) 42.02 ± 10.35;and a significant decrease (P <0.05) in group (3) 51.41 ± 6.60 compared, to the control group (1) 56.49 ± 2.18.

The results also showed, that there was a significant increase (P <0.05) with VLDL concentration in group (2) 29.86 ± 8.06 and; a high significant increase (P <0.05) in group (3) 35.92 ± 9.42,compared with the control group (1) 24.03 ± 4.53.

Table (2): Effect of polycythemia on serum Lipid profile:

Groups Studied Parameters	(1) Control group	(2) True polycythemia (PV group)	(3) Secondary polycythemia (Non- PV group)	LSD
TC (mg/dL)	193.02±5.92[a]	159.20±22.59[b]	197.27±15.96[a]	5.11
TG (mg/dL)	119.83±10.77[c]	148.59±43.27[b]	179.56±61.71[a]	14.78
LDL (mg/dL)	113.69±27.76[b]	92.45±21.67[c]	124.77±44.52[a]	10.67
HDL (mg/dL)	56.49±2.18[a]	42.02±10.35[c]	51.41±6.60[b]	1.91
VLDL (mg/dL)	24.03±4.53[c]	29.86±8.06[b]	35.92±9.42[a]	2.64

- The values represent the mean ± the standard deviation.
- The letters a, b, c indicate a significant difference (P <0.05) between the studied groups depending on the value of LSD.

Effect of polycythemia on Oxidative stress: The results of the current, study showed through Table (3) that there was a significant increase (P <0.05) in the MDA concentration,(nmol/ml) for a group of polycythemia patients, it was; (0.49 ± 0.04) compared to the control group that amounted to (0.07 ± 0.01).

Table (3): Effect of polycythemia on Oxidative stress

Groups Studied Parameter	(1) Control group	(2) Patients group	p value[a]
MDA (nmol/ml)	0.07 ±0.01 [b]	0.49 ± 0.04 [a]	<0.05
Number of samples	40	85	-

Values are,expressed as mean ± SD.
a,b For significant comparison, between control and Patients groups.

Discussion

Polycythemia relationship with gender: Figure (1) shows that the percentage, of polycythemia infection in males increased to 67.46%, while; it decreased in females to 32.54%. The reason for this may be attributed to smoking,as this phenomenon is more common among males than in females.

There is also a relationship, between smoking and an increase in blood viscosity, as smoking causes a significant, increase in the total hemoglobin concentration in smokers compared to nonsmokers. This may be attributed to the, fact that smoking .leads to a decrease in the volume of blood plasma, which causes an increase in the mass of,red blood cells as a result of poor blood supply with oxygen and the lack of,hemoglobin binding With oxygen (Hb-O), thus causing blood poisoning and increasing; its viscosity, the condition worsens with the increase in the duration. and number of smoking. These results are identical to those of[12].

Smoking in all its; forms is considered one of the biggest pests that afflict society and has been described, by the Centers for Health Control and Prevention in the United States as the only preventable. and most important threat to human; health in developed .countries and is the most important cause of premature death worldwide [13] .

As polycythemia is an increase in the number of red blood cells in the blood that usually affects adults over the age of fifty, but it may affect people; in the age group between,fifteen to ninety, and it is more in men compared .to women. It is the abnormal,increase in the number of red blood cells; The percentage of PCV hematocrit reaches more than 52%,in men and more than 47% in women. Which leads to an increase in blood viscosity and the consequent,risks of complications [7].

Polycythemia relationship with age: The current study indicates through Figure,(2) that the incidence of polycythemia**,**increased with age, until it reached its. peak in the third age group (41-50) years old, as the rate was, (34.93), after which the percentage gradually decreased; to a minimum in the fifth age group (61-70) years, it was (10.84). The reason for this may be due to taking some medications, as it was observed that the hemoglobin level increased,significantly when diuretics were taken,, which leads to dehydration,. Also, an increase in the level was observed in severe burns. And stress[14], high blood pressure, and also during long-term tobacco. smoking, as well as the increase, in psychological pressures and difficulties of life and the increase in responsibilities, in this particular age group and the accompanying. psychological and physical stress[15] .

This increase. is true or primary when it includes an increase in the number of white blood cells and platelets in addition' to an increase in red cells, then it is called;(polycythemia vera), This occurs as a result of infection with some diseases such as congenital heart; disease and chronic respiratory disease, as well as smoking,, and living on altitudes where oxygen is lacking[1]. The cause of polycythemia; may also be a defect in the production of the hormone Erythropoietin, which. regulates the production of red blood cells, as in the case of various,body tumors such as those affecting the kidneys, liver, lung, brain and uterus, And the people at risk. of developing erythropoiesis are smokers and those with heart or lung disease And people exposed, to psychological,and physical stress, and people with a family history; of infection[2].

As for the. gradual decrease in the incidence rate after this group, it may be due to the increase in deaths as an inevitable result after suffering, the afflicted person with many;diseases that exhausted his health and;claimed his life[6].

Effect of polycythemia on concentration of hemoglobin and the PCV: The results; of the current study recorded through Table No. (1) the presence of a significant, increase (P <0.05) in both the concentration

of hemoglobin. (Hb) and the PCV packed cell volume, in patients with both types of real and secondary compared to the control group because these two indicators. are the most important characteristics of polycythemia As well as increasing the number of red blood cells., this is in agreement with a study presented by [7].

Polycythemia vera is, a myeloproliferative disorder, when the. body intensively produces red blood cells without. affecting the hormone erythropoietin,. While secondary polycythemia, is characterized by an increase in hemoglobin due to the effect. of that hormone[2].

Effect of polycythemia on serum Lipid profile: Table (2) shows that there, was a significant decrease (P <0.05) in the total cholesterol TC concentration. in group (2) true polycythemia, compared with control group,(1) While a non-significant increase was found in group (3) secondary polycythemia;compared to control group .

This is in agreement, with the study Fujita, H. *et al*.[16] where polycythemia PV is classified as necrotic tumors of the bone, marrow that reduce the level of cholesterol, as a result of the. increased demand for cholesterol by the damaged cell membranes in the bone. marrow [17].

Also, there is a relationship; between the free cholesterol and the red blood cell count RBC, Hb and PCV, It is expected, that the cause of the lack of cholesterol associated with polycythemia vera is the;retention and isolation of cholesterol spread coinciding, with an increase in RBC numbers, This does not occur in secondary,polycythemia due to an increase in all blood components without exception. and not RBC alone as in the case of polycythemia vera [16].

The results; also recorded a significant increase (P <0.05) in the .concentration of triglycerides TG in group (2) and a high significant increase (P <0.05) in group (3) compared, to the control group (1). The reason for this may be due to smoking as well, as many indicated, From studies; to the presence of an increase; in the concentration of serum fats in the blood of smokers[12].

The reason for this increase may be attributed to the fact that smoking works on the presence of different; mechanisms that lead to a change in the level of fats, the .most important of which are: Nicotine stimulates the,sympathetic nerves in the adrenergic gland, which leads to an increase, in the secretion of hormones (Epinephrine and norepinephrine), which leads to an increase; in the lipase enzyme and the concentration; of free fatty acids (FFA) in the plasma, and this leads to an increase in the secretion of (TC) and triglycerides, in the bloodstream[18].

The results indicated; a significant decrease (P <0.05) in the concentration of low-density lipoprotein LDL,in group (2) and a significant increase (P <0.05) in its concentration. in group (3) compared with the control group (1). The cause of the high fat may be the, consumption of diets rich in fat and cholesterol as well as a diet low in fiber and grain content.[14].

As for the reason for the decrease in group (2), it may be attributed to the decrease in the cholesterol level of people with true polycythemia due to the presence of a close;association between them [19] .

The results of the study; also recorded a high significant decrease (P <0.05) in the concentration of, HDL lipoprotein in group (2) and a significant decrease (P <0.05) in group (3) compared,with the control group (1) and the reason may be that lipid metabolism can be It is altered by acute and chronic. infections that participate in increasing,plasma concentrations of cytokines, Studies have shown that a number of cytokines, such as tumor necrosis factor (TNF-α) and interleukin (IL-1β) are believed; to have effects on lipid metabolism and blood change dynamically [20].

Lipolysis increases in adipose tissue, as is the removal of triglycerides neutralized,cholesterol (TG) and low-density lipoproteins (LDL) due to the decrease in the .activity of the lipoprotein lipase enzyme. Thus, any case,raises the level of,cytokines (TNF-α) and interleukin (IL-1β).) In the blood .that has the potential;to cause lipid-raising [14].

The main features; of this catabolic state are lipid peroxidation, elevation of free fatty acids, elevated. cholesterol, level of neutrophilic triglycerides (T.G), and level of low-density,lipoproteins (LDL) [14].

The increased concentration; of LDL in the blood of these,patients leads to the possibility of its deposition in the arteries unites with calcium, and leads to narrowing and hardening of .the arteries, and consequently the occurrence of thrombosis,and arteriosclerosis [19].

High-density .lipoproteins levels (HDL) in the current study showed a significant decrease compared with,the control group. The reason for this may be

attributed to the oxidative stress occurring in the;patients as a result of lipid peroxidation, which is,evident by the high concentration of MDA, and this is consistent with the .findings of Hamza et. al. [21], which promotes lipolysis in .adipose tissues, and the plasma concentration of; free fatty acids increases as it moves to the liver and muscles, and in the liver. some free fatty acids are oxidized; and most of them are returned The process of esterification into (TG) increases. the level of (TG) in the blood and the level of HDL decreases [20].

The results; also showed a significant increase ($P < 0.05$) with the .concentration of very low density, lipoprotein (VLDL) in group (2) and a high significant increase ($P < 0.05$) in group (3) compared with the; control group (1). The reason for this may be attributed to the increase. In triglycerides, because there is a close relationship. between them, according to the equation[21]:

VLDL = TG/5.

It was found that; a high level of triglycerides neutralized .cholesterol (TG) leads to an increase in the .level of very low-density lipoprotein (VLDL) because they contain a large proportion of triglycerides neutralized to cholesterol and thus lower, levels of high-density lipoproteins associated with cholesterol, HDL-C[14].

Effect of polycythemia on Oxidative stress: The results of the current study showed a significant increase in malondialdehyde, (MDA) concentration in polycythemia,patients compared with the control .group, which expresses the presence of oxidative; stress status as the final,product of lipid peroxidation., This is in agreement with results presented by Pérez - Rodríguez L, *et al.*[14] that .demonstrated,that lipid peroxidation index levels,(plasma levels of MDA and hydroperoxidase) contrast with levels of circulating lipids (triglycerides and cholesterol) .

We studied MDA as an oxidative .stress parameter in polycythemia patients and found that there is a close correlation. between the lipid profile and the increased oxidative stress, which believed that, lead to conventional cardiovascular risk factors, and that the increase in lipid;peroxidation is due to the oxidative stress that occurs when peroxides override the antioxidant mechanism and the dynamic balance between oxidants and,antioxidants is disturbed[15].

Several studies have confirmed the .presence of a change in the serum lipid profile during oxidative stress, as well as; a relationship between atherosclerosis and coronary heart disease in patients .with polycythemia [1].

Oxidative stress is caused by an increase. reactive oxygen radicals inside cells, Which in turn,leads to lipid peroxidation, Thus causing cell damage and then death, determination of serum MDA level gives an indication of lipid peroxidation levels[14].

A study presented by Vener *et al*. [6] show that the patients with polycythemia they have an increase in oxidative,stress and that this increase was associated with a high level of,homocysteine.

It has been suggested that increased, oxidative stress may be correlated with vascular .events in as well as the mutagenesis such as JAK2V617F .mutation in PV patients [1].

Aliyazicioglu Y, *et al.* [22]shown. that JAK2V617F mutation played a major role in the pathogenesis of .myeloproliferative diseases, particularly PV, while some studies suggest, that JAK2V617F mutation .may not be the initiator of the disease, It has been found that oxidative stress, parameters were similar in patients who were negative and positive,for the JAK2V617F mutation[2]. They considered that it is late;genetic event can occur in patients with myeloproliferative disease, and The role played by free radicals which causing DNA damage and cellular oxidative,damage pathways[14].

Conclusions

1. The incidence of polycythemia is more common in males compared to females.
2. The age group (41-50) years is,the most likely to have polycythemia.
3. Increased hemoglobin Hb concentration; and compressed cell volume in patients with polycythemia, both true,and secondary types, PCV.
4. Decrease in cholesterol,concentration .in true polycythemia patients compared with the control group.
5. An increase in the concentration .of triglycerides TG in patients with polycythemia.
6. Decreased concentration of HDL for people with polycythemia.

7. The high concentration of low-density lipoprotein (LDL) in patients with secondary polycythemia .and lower in those with true polycythemia.
8. The high concentration of MDA in patients with polycythemia.
9. There is a strong correlation;between oxidative stress and the lipid profile.

Recommendations:

1. Refrain from smoking .because smoking,leads to an increase in the non-oxidized .hemoglobin,to more than 10% of the total hemoglobin rate, and this is accompanied by an increase in the number of .red blood .cells to compensate for the inability of the cells to transport oxygen.
2. Conducting a PCV analysis, the volume of compressed cells, as well as knowing, the percentage of hemoglobin in the blood, and constantly testing the complete blood picture;for patients with polycythemia to avoid the deterioration of the disease and try to correct it.
3. The existence. of a special record for every .family that has people with this disease to know the extent of the possibility of,transmitting it genetically.
4. Donating blood from time to time for people; with polycythemia.
5. Using aspirin under. the supervision of a doctor to reduce blood clotting and increase, its liquidity, and thus reduce the incidence of stroke or coronary heart disease.
6. The patient is advised to drink sufficient quantities of water regularly to maintain. the normal amount of fluids in the body and maintain. the health of the kidneys.
7. We advise the patient. to follow healthy eating method rich in antioxidants and to return to the food pyramid. And leave or reduce the. eating of red meat.

Abstract

Background: This study is concerned with determining the severity of preeclampsia according to the value of serum albumin .Materials and Method : 100 women were divided into 4 groups according to their blood pressure [control (n=22), gestational hypertension (n=25), mild preeclampsia (n=29), severe preeclampsia (n=24)].Concerning about comparison of serum albumin level for each woman . Also the following informations were taken in consideration: age, gestational age, parity, systolic blood pressure and diastolic blood pressure .Results : comparing serum albumin level between the groups shows a significant difference ($p<0.05$). Analysis of data shows a significant difference in age between control and severe preeclampsia ($p=0.04$) . The difference in gestational age was significant between control and other groups ($p<0.05$) and a statistically significant difference in systolic and diastolic blood pressure between the groups ($p<0.05$). Conclusion: This study showed that serum albumin level is lower in mild and severe preeclampsia in comparison with normal and hypertensive cases.

Keywords: *Pregnancy; Preeclampsia; Severe preeclampsia; Serum albumin.*

Introduction

Preeclampsia is a hypertensive disorder with multisystem involvement, usually occurs after 20 weeks of gestation(1). Hypertension approximately occurs in 12-22% of pregnancies(2) . The general prevalence of preeclampsia in pregnancy is between 2-8 % of all pregnancies(3) .Incidence of eclampsia in Baghdad; Iraq according to World Health organization research in 2010 was 20.28%(4). Perinatal mortality rates are increased 2- to 3- folds in hypertensive mothers and early onset preeclampsia is associated with a 4- folds increased in stillbirth risk(1) . During the past two decades, the incidence of preeclampsia has increased by 25% in the united states(5).

Preeclampsia is characterized by an elevated blood pressure equal to or more than 140/90 mmHg on two separated occasions in a previously normotensive woman, accompanied by proteinuria (300 mg in 24 hours) and blood pressure normalizes by six weeks postpartum(6) . Severe preeclampsia is diagnosed in the presence of these criteria: -(1) systolic blood pressure greater than 160 mmHg or diastolic blood pressure greater than 110 mmHg (2) thrombocytopenia – platelet counts less than 100,000µL-; (3) epigastric pain or liver transaminase levels twice normal;(4)pulmonary edema;(5)retinal hemorrhages or papilledema(1).

Hypertensive disorders of pregnancy include : gestational hypertension, preeclampsia, eclampsia and chronic hypertension(7). Gestational hypertension characterized by raised blood pressure of ≥ 140/90 mmHg without proteinuria (<300mg per 24 hours) . Preeclampsia is defined as raised blood pressure of ≥ 140/90 mmHg on two separated readings, that is first discovered in the second trimester of pregnancy and proteinuria ≥ 300 per 24 hours . Eclampsia is preeclampsia

superimposed by convulsions . Chronic hypertension is a hypertension diagnosed before pregnancy[3].

The mechanisms of hypertension in pregnancy are largely unknown[2]. The pathophysiology of preeclampsia is thought to be placental[3]. Women with abnormal pregnancies e.g. hydatiform mole,suggesting that the presence of trophoblast tissue provides a trigger for the illness . Biopsies of placental bed reveal a patchy trophoblastic invasion in preeclampsia. The cause is not known but may reflect abnormal adaptation of maternal immune system[6]. The specific risk factors that predispose to preeclampsia:

1) First pregnancy

2) Preeclampsia in any previous pregnancy

3) family history of preeclampsia

4)Age ≥ 40 years

5)Body mass index ≥ 35

6) Multiple pregnancy

7) Proteinuria ≥0.3g/24 hour or diastolic blood pressure ≥ 80 mmHg at booking visit

8)preexisting diseases including e.g. renal disease, diabetes, antiphospholipid syndrome,chronic hypertension and autoimmune disease[6,8].

Prevention of preeclampsia is best started before 16 weeks gestation in which most of the transformation of the spiral arteries occurs,to avoid the maternal and perinatal complication[9] .

1. Dietary changes and exercise: Interventions include aerobic exercise and weight loss,reduce salt intake,increase potassium intake, zinc supplementation and magnesium supplementation[3,9].
2. Trial of aspirin: A trial of aspirin(150 mg) might be effective in prevention of preeclampsia if used at week 16 till the end of 32 weeks of pregnancy[3].
3. Vitamin D may have a protective role against preeclampsia [9] .
4. Antioxidant vitamins: A high dose of antioxidants e.g. vitamins E and C can be used for preeclampsia prevention [3].

Complication of preeclampsia[10]:

A. Maternal Complication

1. Seizure
2. Hypertensive encephalopathy or cerebral edema due to vasospasm and hypoxia
3. Intracranial hemorrhage
4. Renal dysfunction
5. Retinal detachment
6. HELLP syndrome (defined as : hemolysis, elevated liver enzyme levels and low platelet levels) .
7. Placental abruption
8. Systolic and diastolic myocardia dysfunction and pulmonary edema .
9. DIC and hemorrhage
10. Death

B. Perinatal Complication: Including stillbirth or neonatal death, bronchopulmonary dysplasia, oligohydramnios and fetal growth restriction, it has been estimated that 9-20 % of stillbirth is directly related to hypertensive disorder of pregnancy. Preeclampsia is a significant contributor to iatrogenic preterm birth and neonatal morbidity[11].

Material and Method

This cohort study was done in Al Samawah maternal and child teaching hospital, enrolled between August 2018 and November 2018 .Total 100 women,age between 17-26 years who participated in the study were divided into 4 groups:

1. Control group; 22 women having no hypertension.
2. 25 women with hypertension and no protein in urine.
3. 29 women with mild preeclampsia.
4. Severe preeclampsia group consist of 24 women.

This study was approved the medical ethics committee of the college of medicine university of Al Muthanah . In the selected cases we exclude chronic illnesses such as chronic kidney diseases, chronic hypertension and diabetes mellitus.

We are concerned about the age,weeks of gestation, systolic blood pressure and diastolic blood pressure for each woman in this study . A blood samples were aspirated for the estimation of serum albumin level and the reference value is 3.40 g/dl – 4.8 g/dl . For estimation of albumin in urine, a random urine specimen was collected and a dipstick urine measurement for albumin was done . To evaluate the distribution of blood pressure and serum albumin we divided the groups into 2 subgroups according to the age : G1(17-21) years and G2 (22-26) years.

Results

The results of the distribution of blood pressure and serum albumin are shown in Table (1). There was no significant difference between the age groups (p>0.05) for all our involved groups.

Table (1): Distribution of systolic,diastolic blood pressure and serum albumin according to age groups for control, Gestational hypertension, mild preeclampsia and sever preeclampsia groups.

Sever Preeclampsia			Mild Preeclampsia			Gestational Hypertension			Control			Age groups (years)
Serum albumin g/dl	DBP	SBP	Serum albumin g/dl	DBP	SBP	Serum albumin g/dl	DBP	SBP	Serum albumin g/dl	DBP	SBP	
2.855± 0.050	113.56± 3.358	163.44± 2.651	3.136± 0.087	103.50± 2.309	152.56± 1.788	3.44± 0.04	94.75± 3.38	142.58± 2.021	3.621± 0.111	79.00± 1.12	114.75± 4.35	G1 17-21
2.841± 0.044	116.60± 3.680	166.40± 3.776	3.167± 0.078	104.46± 2.634	153.23± 2.242	3.415± 0.053	97.15± 2.57	144.38± 2.181	3.616± 0.112	78.10± 0.99	115.9± 3.87	G2 22-26
0.649	0.857	0.212	0.463	0.445	0.468	0.065	0.431	0.90	0.979	0.750	0.102	P value

*Represents a significant difference at p≤0.05 using independent sample T test. Data are expressed as Mean ±SD .SBP=Systolic blood pressure (mmHg).DBP=Diastolic blood pressure (mmHg).

Maternal Characteristics Analysis: The clinical characteristics of 100 pregnant women are shown in Table (2). There were no significant differences in age between control group and gestational hypertension (p= 0.65), control group and mild preeclampsia group (p=0.9) . But there was a significant difference between control group and severe preeclampsia group (p =0.04).

The analysis of parity shows no significant between control and gestational hypertension, mild preeclampsia and sever preeclampsia (p= 0.84, p = 0.51 and p= 0.23 respectively) .

Gestational age analysis shows the following results; the differences between control and the other groups were significant (p < 0.05).

Table (2): Comparison of maternal characteristics between control,gestational hypertension, mild and sever preeclampsia groups.

Number	Control	Gestational hypertension	Mild Preeclampsia	Sever Preeclampsia	P value
	22	25	29	24	
Age (years)	21.091±1.477	21.320±1.2819	21.034±2.3827	22.125±1.4283	a-0.111 b-0.65 c-0.9 d-0.04
Parity	0.818±0.795	0.76±0.83	1.00±1.10	1.167±1.12	a-0.47 b-0.84 c-0.51 d-0.23
Gestational age (weeks)	39.045±0.7854	37.8±0.7638	36.00±0.8018	36.00±0.978	0.000

*Represents a significant difference at p ≤ 0.05 using ANOVA. Data are expressed as Mean ± SD./=statistical analysis is not implemented. a-represents the total difference between the groups, b-represents the difference between control and gestational hypertension, c-represents the difference between control and mild preeclampsia,d-represents the difference between control and sever preeclampsia. NS = not significant.

Serum albumin and blood pressure analysis: The results are shown in Table (3) . The analysis shows a statistically significant difference in serum albumin level between control,gestational hypertension,mild preeclampsia and sever preeclampsia ($p<0.05$)

There was a statically significant difference in systolic and diastolic blood pressure between control and the other groups ($p<0.05$).

Table (3): Comparison of serum albumin,systolic and diastolic blood pressure between the studied groups.

	Control	Gestational Hypertension	Mild preeclampsia	Sever preeclampsia	P value
S. albumin g/dl	3.61±0.109	3.42±0.048	3.15±0.0831	2.84±0.046	0.000
Systolic blood pressure (mmHg)	115.27±4.18	143.52±2.256	152.86±2.38	165.29±3.64	0.000
Diastolic blood pressure (mmHg)	78.59±1.14	96.00±3.17	103.931±2.46	115.458±3.79	0.000

*Represents a significant difference at $p \leq 0.05$ using ANOVA. Data are expressed as Mean ± SD.

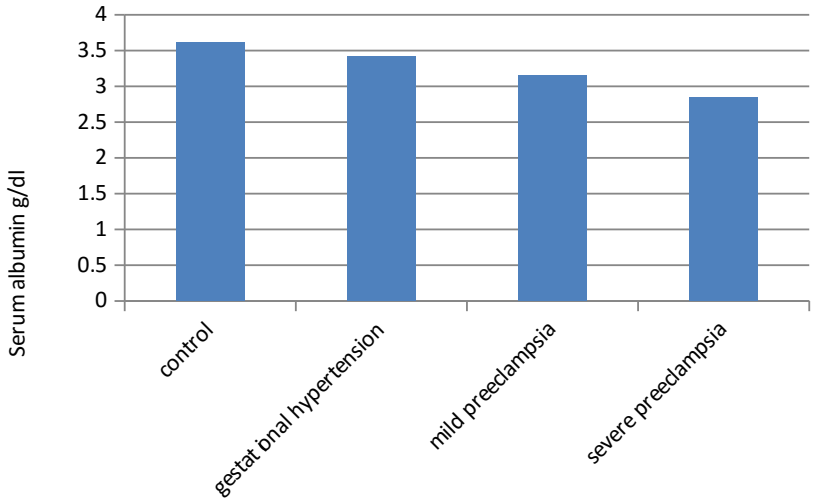

Figure (1): Bar chart shows serum albumin level in each group

As shown in Figure (2); women with mild and sever preeclampsia will give birth preterm.

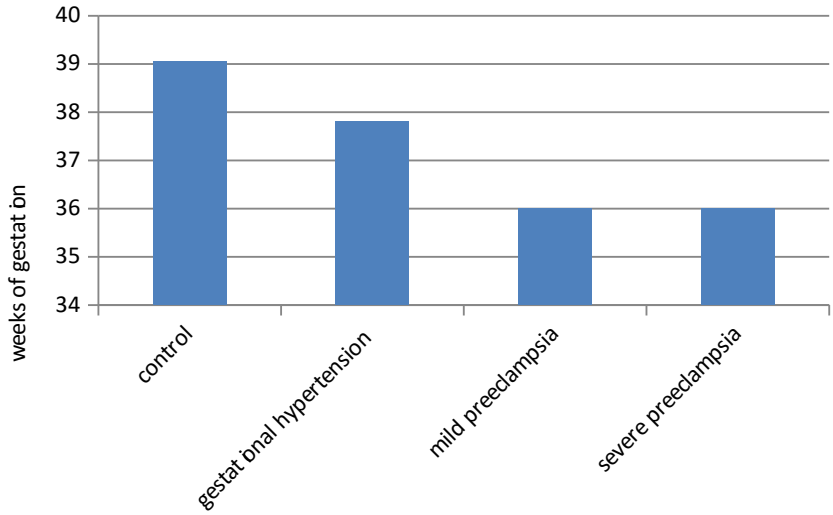

Figure (2): Bar chart shows gestational age in each group

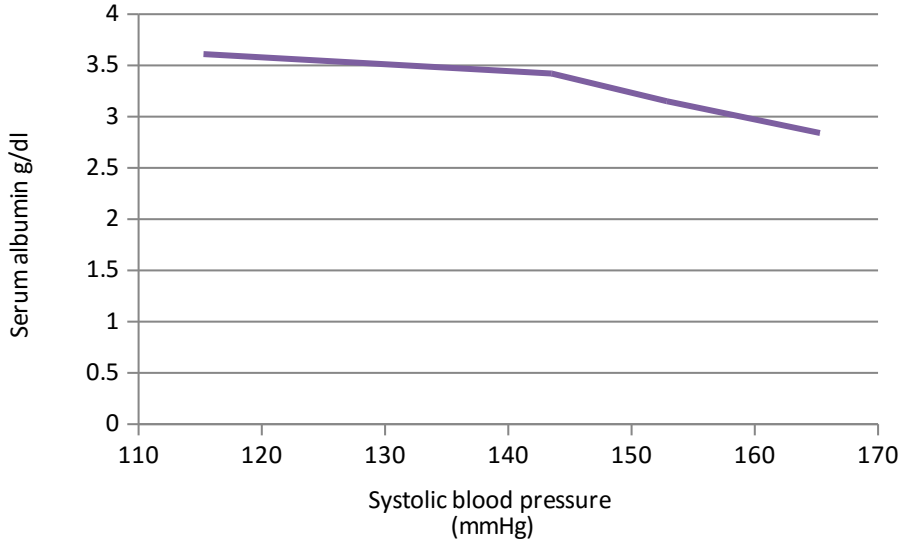

Figure (3): The correlation between systolic blood pressure and serum albumin level

Discussion

Preeclampsia remain a leading cause of maternal morbidity and mortality . This study has shown a significant relation between severe preeclampsia and low gestational age either due to iatrogenic termination of pregnancy or due to preterm labour . This agreed by Cruz, et al[12] and Chen H,et al[13]. This study found that serum albumin level is significantly related to the severity of preeclampsia . This agreed by Gojnic, et al [14] where 60 patients diagnosed as preeclampsia and nearly all severe cases had albumin values below 3g/ dl .According to this results parity is not related to the severity of preeclampsia . This is agreed by a study done by Basima Al Ghazali, et al[15] where 100 patients were divided into 4 groups and found that no significant difference in parity when comparing between the groups.

Conclusion and Recommendation

This study showed that serum albumin level is lower in mild and sever preeclampsia comparing with normal and hypertensive cases. Prediction of severity of hypertensive disorders in pregnant women is possible with serum albumin level and they should have their Serum albumin level measured .

Ethical Clearance: The Research Ethical Committee at scientific research by ethical approval of both environmental and health and higher education and scientific research ministries in Iraq.

Conflict of Interest: The authors declare that they have no conflict of interest.

Abstract

Amebiasis is an important cause of diarrheal disease worldwide and has been associated with childhood malnutrition. *E.histolytica diagnosed* usually by microscope, which consider as traditional diagnosis and are neither sensitive nor specific detection of *Entamoeba histolytica*(1). Real-time PCR assay developed for sensitive and specific detection of the intestinal Protozoan parasites *Entamoeba histolytica* directly from human feces(2). The RT-PCR assay was able to detect as little as 0.1 parasite per g of feces(3). The current study based on Phosphoglycerate kinase gene (PGK) is a major enzyme used in glycolysis, in the first ATP-generating step of the glycolytic pathway so the PGK is an enzyme that catalyzes the reversible transfer of a phosphate group from 1,3-bisphosphoglycerate (1,3-BPG) to ADP producing 3-phosphoglycerate (3-PG) and ATP(4). In our study, depend on PGK as target for Real time PCR assay for detection the trophozoite stage of *E.histolytica* in stool samples of infected persons.

In the current study, a total of 300 human fecal samples were collected from children (less than one year-15 year) that suspected to infection with *amoebiasis* which admitted to hospitals and primary care centers in the city center, Al-Hindiya district and Nahiat Al -Hurr (100 samples from each region) during the period from February 2019 to January 2020. Fecal samples processed by direct wet smear and formalin ethyl acetate concentration method followed by iodine staining and was microscopically examined for *E.histolytica*. Microscopically positive samples were then subject to Real-time PCR. This is the first study in Iraq using the Phosphoglyceratekinase gene as target for molecular techniques to determine the presence of *E. histolytica* trophozoites.in stool samples.

Keywords: *Entamoeba histolytica, Real-Time PCR, Phosphoglycerate kinase gene.*

Introduction

Entamoeba histolytica is an intestinal protozoon of humans. Several species of the genus *Entamoeba* infect humans, includes: *Entamoeba histolytica,, Entamoeba coli, Entamoeba dispar. Entamoeba polecki, Entamoeba gingivalis and Entamoeba hartmani*(5). Among these, only *E. histolytica* considered as pathogenic organism for human and the disease it causes is called amoebiasis or amoebic dysentery(6). *Entamoeba histolytica* is an enteric parasite, its normal habitat in the human intestinal lumen and has the capacity to invade the epithelium. Amoebic dysentery occurs when *E. histolytica* trophozoites invade the walls of large intestines and multiply in the mucosa, forming ulcers. Most frequent manifestations of infection are dysentery, weight loss, fatigue, flatulent stomach, colitis, and abdominal pain. A common outcome of invasion of the amoeba into tissues is liver abscesses, which can be fatal. *E.histolytica* has ability to secretes tissue lytic enzyme, histolysin which caused damage to the mucosal epithelium(**6**), which digest the intestinal wall tissue of the infected individual hence the Latin name, is to (tissue) lytica (destruction)(7).

The traditional laboratory diagnosis of Entamoeba infections via microscopic examination of stool samples, fresh or fixed. The pathogenic amoeba, *E. histolytica* is indistinguishable from *E. dispar* and *E. moshkovskii*, the non-pathogenic species(8). It has also been shown that the sensitivity and specificity of microscopy is less optimal in differentiating the various species of Entamoeba (9).

Real-time PCR is a very attractive methodology for laboratory diagnosis of infectious diseases because of a lack of requirement for post-PCR analysis, resulting in shorter turnaround times and reduces the risk of amplicon contamination[10]. This reflects evident progress in diagnostics, in which the contaminated of amplicon consider as the major reason of false-positive results in PCR assay[11] Also the real-time PCR is a quantitative method and capable of identified the parasites number in various samples[12].

The human parasite *E. histolytica*, depends only on glycolysis for its ATP supply because it lacks the Krebs cycle and oxidative phosphorylation pathways[13,14]. The glycolytic enzymes of the parasite are highly divergent from the enzymes present in the human host; they include an AMP-inhibited hexokinase [15,16], and the non-allosteric and pyrophosphate-dependent enzymes phosphofructokinase ATP–PFK-1 and pyruvate kinase in the host [17].

The importance of glycolysis for parasite survival and the differences found in the glycolytic enzymes compared with those of the human host, make this pathway a suitable target for molecular techniques such as RT-PCR assay [18].

Materials and Method

1. **Sample collection:** Fecal specimens included in this study were from children admitted to hospitals and primary care centers in the center of the city, Al-Hindiyah district and Nahiat Al -Hurr (100 samples from each region collected from children aged less than one year to 15 years) during the period from February 2019 to January 2020. All positive samples that detected microscopically were stored at −70°C until used in RT-PCR assay.

2. **Conventional Microscopy:** One drop of fecal suspension transferred to a microscope slide with a cover slip. Each slide examined as a direct mount at 40- magnification and presence or absence of *E.histolytica*trophzoites were recorded. For further confirmation, formal–ether concentration technique was performed [19].

3. **DNA extraction:** Genomic DNA was extracted from trophozoites . The trophozoite's DNA extracted using AccuPrep® Stool DNA Extraction Kit (Bioneer, Korea) according to the manufacturer's instruction with some modification and used as template for RT-PCR assay. Extraction of genomic DNA from *E.histolyticatroph.* was carried out according to our previous published paper [19].

4. **RT-PCR amplification:** One set of primers was design to use against the coding region of the Phosphoglycerate kinase gene (in *E.histolytica*trophozoites)a 119bp fragment was amplified using the forward primer (ACCCAA GCT GGT GTTTTGAC)and the reverse primer (AG TTCA AGT GATGC TCC T CCTC)To amply the DNA by used of the forward and reverse primers which designed by NCBI site.

5. **RT-PCR protocols:** Real-Time PCR was performed for detection of trophozoites stage of *E.histolytica* by using the primers and TaqMan probe specific for Phosphoglycerate kinase gene In the DNA technique was carried out according to method described by[3].

6. **Real-Time PCR master mix preparation:** Real-Time PCR master mix prepared by one-step Reverse Transcription and Real-Time PCR detection kit (AccuPower Rocket ScriptRT-PCR PreMix, Bioneer. Korea), and done according to company instructions.

   The RT-PCR master mix reaction components that mentioned in were added into standard qPCR tube containing (8 wells strips tubes which containing Rocket Script reverse transcriptase and TaqMan probe premix). Then all strips tubes vortexing for mixed the components and centrifuge for 3000 rpm for 3 minutes in Exispin centrifuge, after that transferred into Exicycler Real-Time PCR thermocycler[3].

7. **Real-Time PCR Thermocycler conditions:** Real-Time PCR thermocycler conditions was set up according to primer annealing temperature and RT-PCR Taq Man kit instructions.

   Thermal cycles were applied to inspect the Real-Time PCR and relying on instructions AccuPower® 2X GreenStarTM qPCR Master Mix as well as by calculating the degree Tm prefixes using the device MiniOpticon Real-Time PCR systemBioRad/USA.

8. **Real-Time PCR Data analysis:** RT-PCR data analysis performed by calculation the threshold cycle number (CT value) that presented the positive amplification of gene in Real-time cycle number (20).

Statistical Analysis: The results were analyzed statistically by Chi-squared test, significant results were

attributed to probability values $P < 0.05$ by using SPSS program.

Results

This study included 300 stool samples of diarrhea collected from children suspected infected with *E.histolytica,* the microscopic detection appeared 194 positive samples(100 samples from Kerbala center showed 55 positive samples (55%), 100 samples from Al-Hindiyah district showed 62 positive samples(62%) and 100 samples from Nahiat Al –Hurr appeared 77 positive samples(77%)

Table 1. Frequencies and percentages of Socio-demographical characteristics (N. of positive samples=194/300)

Socio-Demographical Characteristics	Groups	F	Percentage (%)
Gender	Male	107	55.2
	Female	87	44.8
Age Groups	< 1 year	23	11.9
	1- 5	67	34.5
	6-10	72	37.1
	11-15	32	16.5
Region	Kerbala center	55	28.6
	Al-Hindiya	62	32
	Al -Hurr	77	39.7
Education Levels	Nursery school	23	11.9

	Primary school	78	40.2
	Secondary school	21	10.8
	School dropout	23	11.9
*F. =frequency			

Comparison of microscope diagnosis with RT-PCR assay: The microscopic examination results of showed for 300 stool samples showed that only 194 samples contained the Trophozoite stage of *E.histolytica*in the percentage (64.7%) while (35.3%) of the samples were negative for the parasite. The molecular examination by RT-PCR of the same samples revealed that the positive samples was 243 and the percentage was (81%) while the percentage of samples negative was (19%). (Table:2)

Table (2) Infection percentage of parasitic *E.histolytica* by microscopic examination and RT - PCR results.

Negative (%)	Positive (%)	Method of examination
106(35.3%)	194(64.7%)	Microscope
57(19%)	243(81%)	RT-PCR

Molecular identification using the Real Time – PCR assay: The results of molecular examination by using of RT-PCR appeared that the number of positive samples are 243(81%) from 300 suspected infected samples, depending on this technique the distribution of infection with *E,histolytica* in three region illustrated in table(3).

Table (3): The percentage of the infected with *E.histolytica* in the city center, Al-Hindiya and Al – Hurr which diagnosed by RT-PCR assay.

Region	Positive samples	Percentage
Karbala center	63	25.9%
Al-Hindiya	86	35.4%
Al -Hurr	94	38.7
Total	**243**	

The used of RT-PCR assay in the specific detection of *E.histolytica* showed a fluorescence of SYBER Green dye which appeared very clear through formed of amplification plot to the positive samples during the cycle 30 as shows in the fig. (1).

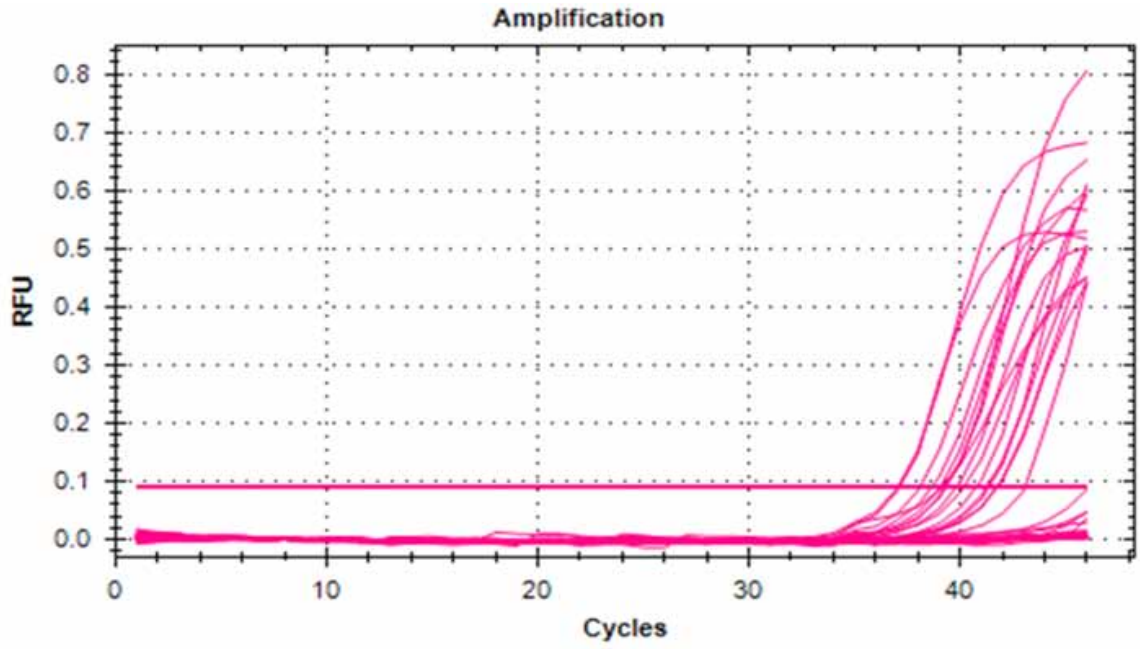

Figure (1): Amplification Plot of Phosphoglycerate kinase gene, in which the fluorescence of the dye SYBER Green represent samples positive located above of threshold while the negative samples located below the threshold.

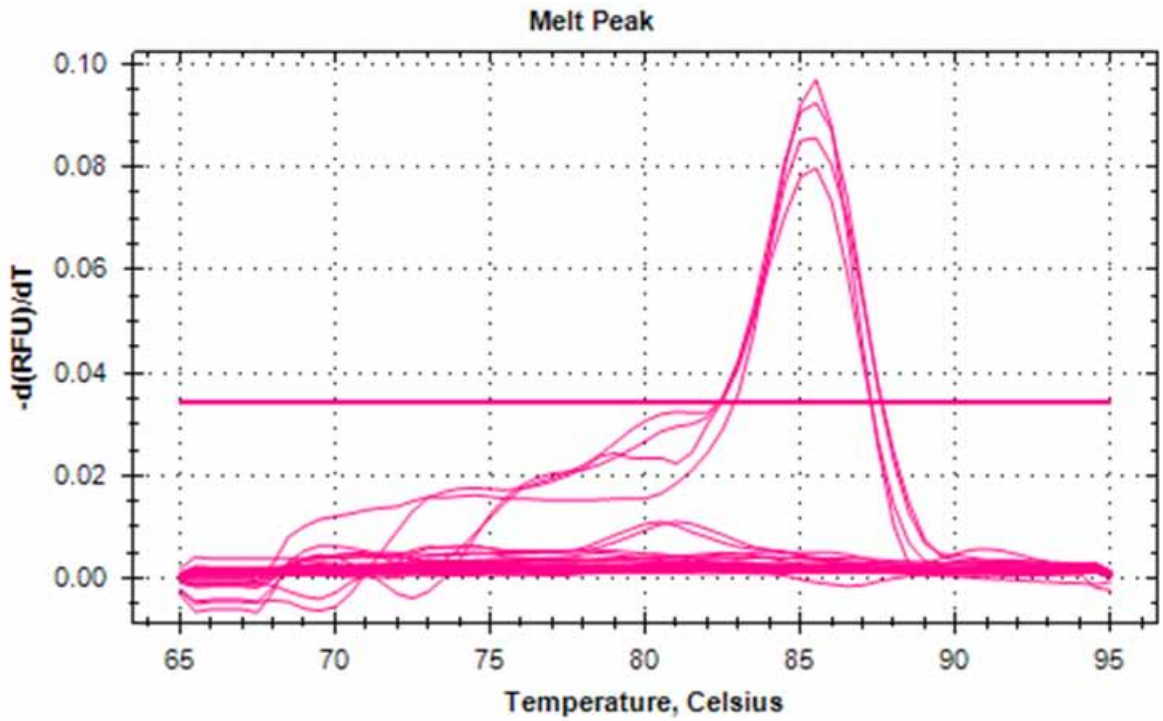

Figure (2): Melt peak curves from real-time PCR amplification of Phosphoglycerate kinase gene. Positive samples indicated in the curves (shown above of Threshold, and negative samples shown under the threshold).

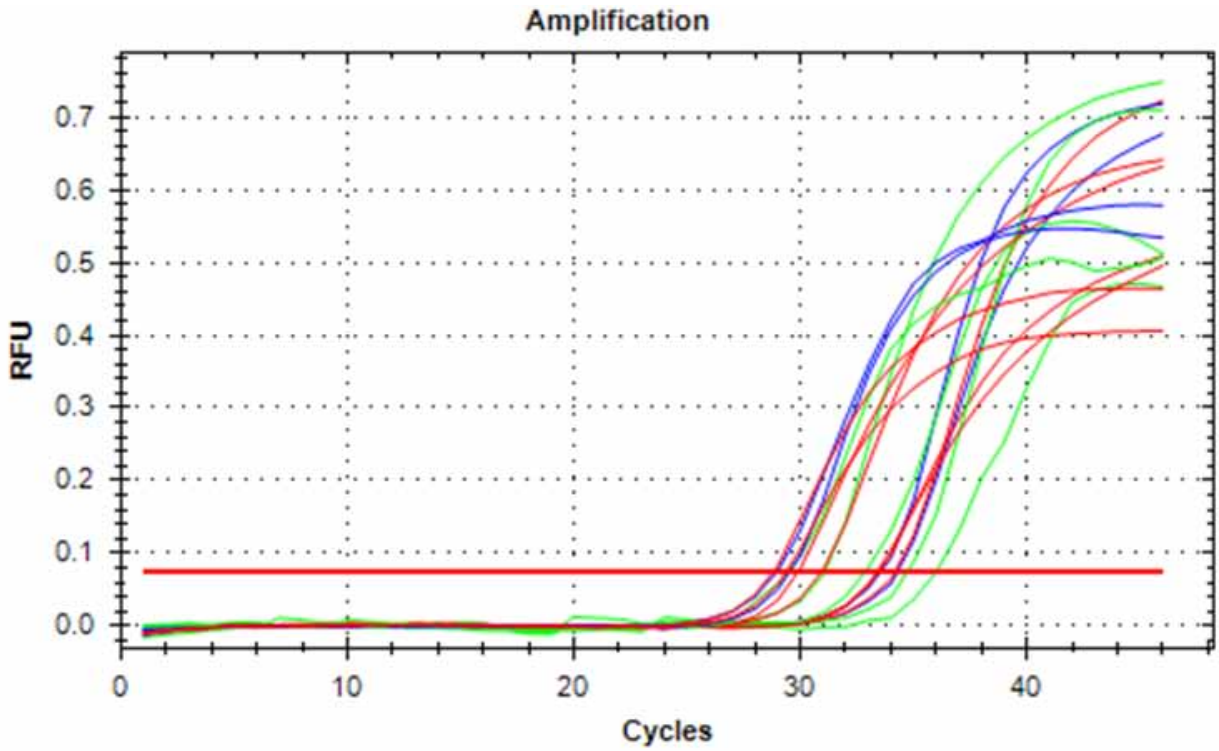

Figure (3): Amplification plot of Phosphoglycerate kinase gene appeared the positive samples of *E.histolytica* trophozoites in the three region: *The center of the city(Red curves), Al –Hurr (Blue curves) and Al-Hindiyah (Green curves).

Discussion

Amoebiasis is a human disease caused by species of protozoa *Entamoeba histolytica,* which causes widespread morbidity and mortality worldwide distribution occurred diarrheal disease and abscess in several parenchymal tissues such as liver, lung, and brain. The true prevalence of infection is unknown for most countries due to the difficulty to characterize *Entamoeba histolytica* from other non-pathogenic amoebas, which have, resemble morphology, like *Entamoeba moshkovskii* and *Entamoeba dispar*[21].

Socio-demographic characteristics: The current study appeared the prevalence of *E.histolytica* was 64.7%. From the diarrheal samples that collected from suspected infected patients. This prevalence considered high rate when compared to other survey studies conducted in other countries in the world, for instance, a study in Nigeria show the prevalence of *E.histolytica* infection in the 183 child examined 78 (42.62%) were infected with *Entamoeba histolytica*[22]. Also a survey was carried out in Pakistan to determine the prevalence of human amebiasis. During the study, 1360 fecal samples were examined 295 (21.69%) were infected with *E. histolytica* [23]**.**

In other study results showed that the prevalence of *E.histolytica*was (2.2%) in 576 fecal samples were collected from children suffering from acute diarrhea in Saudi Arabia[24] .also our results is closely related to[25], where it was 53.18% in her study to diagnose *E.histolytica*in patients with gastrointestinal symptoms in an endemic region in Turkey. While our results were higher than results of Erbil (2.33%)[26] and in Babylon (17.4%)[27]. They are several reasons of the high prevalence of the *E.histolytica* may be due to direct transmission by contaminated food and water, insufficient attention to hygiene[28]. The difference of the results in the present study compared to other studies may be due to the difference in the sewer efficiency, personal hygiene, the density of population, geographical location, the number of test samples, the different duration of the study, different in the living style and different ages[29].

In the current study found the prevalence rate of *E. histolytica* in males (55.2%) was higher than females

(44.8%) and there is no significant relationship (p< 0.05). These results may due to that, males are more susceptible than females to infections, because males generally exhibit reduced immune responses and increased intensity of infection compared to females [30]. These differences are usually duo to physiological and ecological factors, which is usually hormonal in origin. Ecological factors include differential exposure to pathogens because of sex-specific behavior or morphology [31]. Other close cause of variation in ability to infection between two sexes is due to differences in endocrine-immune interactions. Male sexually mature are often more susceptible to infection, because sex steroids, specifically estrogens in females and androgens in males, modulate several aspects of host immunity. In addition to affecting host immunity, sex steroid hormones also alter genes and behaviors that influence susceptibility and resistance to infection. Thus, males may be more susceptible to infection than females not only because androgens reduce immune competence, but because sex steroid hormones affect disease resistance genes and behaviors that make males more susceptible to infection[32].

The highest prevalence of infection according to the age was (37.1%) in the age group (6-10) years. The difference between the age groups in term of infection distribution in this study was statistically significant (P > 0.05) while the results of research done in Erbil province find the highest infection rate was in the age (4-6) [32]. Another study revealed the relationship between age and *E. histolytica*, there was a highest prevalence (30.82%) in age group of (1 day to 15) years [33]. while a study results in Kenya appeared no significant association between prevalence of *E.histolytica*and age[34]. Also our results in agreement with [35] who confirmed that children in northern Pakistan under 15 years of age are very susceptible to infection *by E histolytica*. They obtained 27% prevalence of the disease in children under 15 years of age perhaps the reason is duo to they are less care for hygiene compared to adults, also the high incidence of Parasitic infection among school children may be due to the poor sanitary conditions in the most of the schools [36],also they do not take care of their personal hygiene and not washing hands before eating,while some studies showed a reduced in risk for infection with intestinal diseases among children who follow health instruction[37] .

The current study aims also to compare infection rates among three regions in holy Kerbala province, the first region was the Kerbala center, the second region was Al-Hindiya and the third region was Al-Hurr.

The findings of this study, the highest rate of infection was (39.7%) in Al-Hurr region compared to the Kerbala center (28.6) and Al-Hindiyah (32%) was statistically not significant (P<0.05) and this variation may be due to many interacted factors like, low education of mothers, sanitary service, improper water supply because *E. histolytica* can be transmitted orally by drinking water and it is one of the environmental contaminants of the water supply [38] also malnutrition and absence of regular hygiene toilets, which significantly increases susceptibility to *Entamoeba histolytica* in children, in addition to environmental, economic and social factors are also playing a role in this matter [39].

Comparison of microscope diagnosis with RT-PCR assay: Fecal samples collected from suspected infected children with *E.histolytica* which first subjected to microscope that showed 194 positive samples then subjected to PCR analysis. Prevalence of *E. histolytica* was found to be 64.7%(194/300) samples based on microscopy versus 81% (243/300) according to the results of RT- PCR. Remarkably, all samples positive by microscopy were also positive by RT-PCR which was more sensitivities than the microscope detection. The data show that prevalence of *E. histolytica* in Kerbala is higher when specific diagnosis method are used instead of traditional microscopy, allowing to differentiate between morphologically identical human amoeba's species. Microscope detection has always been used to diagnosed of *E. histolytica* in fecal samples. Despite its inability to distinguish and differentiate *E. histolytica* from the morphologically identical nonpathogenic species *E.moshkovskii* and *E. dispar* . This has resulted in the unnecessary treatment of a large number of individuals with anti-amoebic drugs as well as providing an inaccurate picture of the epidemiology of the organism and the disease [40].

The REAL-TIME assay have been shown to be directly comparable in terms of sensitivity and robustness, capable of detecting 10 parasite genomes but not one, unaffected by the presence of DNA derived from the host or the other test species [41]. In our study we depend on different gene Phosphoglycerate kinase gene is a major enzyme used in glycolysis in E.histolytica trophozoites,the researches regarding on this gene was rare,so we used this gene to improved if It could be adopted as diagnostic gene so we searched and used this

gene as a target of RT-PCR and the results showed a high sensitive of this technique to detected this gene in trophozoites stage .

Conclusions

The following conclusions were conducted from the present study:

1. Although the routine tests such as clinical examination, macroscopic and microscopic diagnosis important, but it is unable to qualitative diagnosis of intestinal amoeba species and differentiated among them.
2. Using of the molecular method such as REAL-TIME PCR which characterized by highly accuracy, but these method expensive economically compared to routine method.
3. The use of specific primers in RT-PCR for diagnosis of Phosphoglycerate kinase gene are proven for diagnosis of *E.histolytica* trophozoites that isolated from stool samples of suspected children infection with *E.histolytica*.

Determining the Endpoint of Sediment Titrations by Smartphones

Muhaned Mohammed Eteya

Assistant Lecturer, Department of Chemistry, Thi-Qar Education Directorate, Thi-Qar, Iraq.

Abstract

In this research work, we have used the image processing technique for determining the end of sodium sulphate with standard barium chloride in precipitation titration. The white precipitate of barium sulphate produced by the reaction of barium chloride and sodium sulphate was dispersed in deionized water by magnetic stirrer and its images were taken by mobile phone camera. The resulting pictures were analyzed by Photoshop Software which shows that the intensity of magenta colour has maximum sensitivity by changing the mass of barium sulphate. Therefore; magenta colour was selected as the optimum colour. Also, to depict the calibration curve of sulphate anion, different concentrations of sulphate were prepared in buffered solutions and by addition of barium chloride to them, the intensity of magenta colour was calculated. The results show that the calibration curve was linear in the range of 5-75 $mg.L^{-1}$ of sulpahte with a correlation coefficient of 0.973. Finally, by titration of different real samples such as Tap, river and mineral waters containing sulphate anion with standard barium chloride, the variation of magenta colour was recorded and the concentration of sulpahte anion was determined.

Introduction

Sedimentary Titration: Sedimentary titration is one of the strongest titration techniques, which belongs to the middle the year is 1800 AD. The endpoint in these titrations is based on sudden changes in the physical properties of the solution. There are many method for determining the endpoint in titration method, among which we can mention three common and widely used method. Determining the endpoint by a sudden change in the conduction of voltage or current between two electrodes and the determination of the endpoint is determined visually by changes in the color of the solution made by the detector. And determining the endpoint by changing the absorption of light by titrant or analyte[1]. It should be noted, however, that this method does not apply to sedimentary titrations it is essential to select a standard method or method for determining the concentration of ions in solutions.

Hence, for anions such as halides, gravimetric and sedimentation titration method can be used. However, it should be noted that in general, the gravimetric method can be used only when the solution contains only analytes and is free of disturbing species. For example, when several halide ions are present in the system, the gravimetric method can only obtain the total concentration of ions but can not differentiate between them[2]. In contrast to this method, with the deposition titration method, partial halide ions can be measured separately by sedimentation titration method (due to the difference in their solubility in water). Therefore, sedimentation titration techniques are superior to gravimetric techniques. Since the co-precipitation process occurs frequently in sedimentary method and it is also difficult to detect the endpoint of sedimentary titrations in dye solutions, potentiometric method are mainly used to detect endpoints in sedimentary titrations[3]. In decomposition chemistry, Riley et al.[4,5] for the first time used a small amount of dye solution

instead of a detector in titration method. Based on this, different method based on color intensity changes were used for acid and base reactions[6–10] and metal detectors[7,7,9,11–16].

Today, one of the most important anions to measure is the sulfate ion. Sulfate is one of the major anions in drinking water and may be present in natural waters in concentrations ranging from a few milligrams to several thousand millilitres per litre. The presence of sulfate in drinking water can give it a bitter taste and very high amounts can cause gastrointestinal upset in humans[17].

Determining the correct concentration of sulfate ions in each water source is one of the basic tests in assessing chemical quality. Therefore, measurements that can determine valid data according to the conditions of each laboratory and available water sources are important. Measurement of sulfate ion concentration in drinking water samples is often done by two method of turbidity measurement and iodometric titrations, each of which has certain advantages and disadvantages.

The experimental method of measuring sulfate: To calculate the actual amounts of sulfate anion in the samples and compare with the proposed method. The following technique was used. One of the most common method is turbidity measurement to measure sulfate in the range 1- 40 mg per litre is suitable. Sulfate ion in the acidic environment by chlorobarium. The standard is in the form of insoluble barium sulfate and the amount of light absorbed by the solution. Barium sulfate suspension is measured using a standard sulfate concentration curve is calculated[18].

And there is a way too simple and inexpensive way to measure sulfate anion in ‹ samples in this study of a new method. Different blue has been used. After preparation of barium sulfate from the reaction of barium chloride and sodium. A certain mass of it is dispersed in 1 ml of distilled water and sulfate by the phone camera. The smart is photographed from the solution. The intensity of the purple colour was determined through image analysis. Barium sulfate shows the greatest changes with mass change. So purple too optimal title selected. By recording changes in the intensity of purple colour according to the change in the concentration of sulfate anion, it was determined that the curve calibration is linear in the range of 5-75 mg/L and has a relative standard deviation of 743%. By examining the effect of other ions, it was found that this method can measure sulfate in surface water samples. Finally, this method was used to measure sulfate in river and mineral water. Samples of different waters such as city water.

Reagents and working solutions:

Chemicals used: Deionized water was used in all stages of the experiment to prepare samples. Sodium salt/solution with a concentration of 1000 mg/L of sulfate ion was prepared by dissolving 0.1485 sulfates of German mercury in 100 ml of deionized water. Barium chloride from acetate company) of German mercury was prepared. To make a buffer from magnesium chloride salts (Merck Germany) Sodium German Merck (and Potassium Nitrate) Sigma Aldrich USA (with acetic acid) German Merck (used).

Used devices: Samsung Note 3 camera was used to capture images. Also from the application Company Designed and built and shown in Figure 1.

Figure 1. The internal layout of the lightbox used to capture images

Basis of the method: As mentioned in the previous chapter, this project is based on determining the endpoint of sedimentary titrations. It is concentrated by 9.16 g of barium chloride and 5.32 sodium sulfate by smartphones. For this purpose. We weigh sodium sulfate and then perform the following steps:

Add 250 ml of distilled water to sodium sulfate and 250 ml of distilled water to barium Chloride. Add sodium sulfate solution to barium chloride solution and then stir for two the watch. After mixing the mixture, leave it for 24 hours to get a white deposit the deposition is $BaSO_4$. After precipitation $BaSO_4$ should be stored at 40 °C for 72 hours to be ready to use. The buffer solution was prepared according to the following instructions. 3 g of $MgCl_2$ ، 0.5 g of 0.1 g of KNO_3 sodium acetate salt and 2 ml of 99% acetic acid solution in a 100 ml jouette balloon to prepare the desired buffer. To 0.001 g of barium sulfate precipitate 1 ml to optimize different parameters, it was first added distilled water and in a small cell (5 ml) was stirred for 2 minutes with a stirrer, then the intensity of purple colour was processed to examine its changes. It should be noted that to measure sulfate in real samples, the titration method is used. The buffer solution is added then by adding 0.5 ml of sample 0.2 in which different volumes of distilled water and barium chloride record the intensity of purple colour in the resulting turbid mixture.

Discussion of Results and Optimization

Optimization of various parameters:

Optimizing the intensity of different colours: Turquoise ، Yellow ، Mix of three colours red, green, blue ، Blue ، Green ، Different colours including red-purple and black to find the colour with the highest sensitivity to the mass of barium sulfate were studied, the results of which are shown in Table 3- 1. As it is known purple colour because it is more intense for different amounts of barium sulfate, Was selected as the optimal colour. As a result, this colour was used in the measurements.

Table 3-1. The slight intensity of different colors for barium sulfate

Sample number	g	K1	Y2	M3	C4	Sample RGB5	Sample B6	Sample G7	Sample R8
1	0.001	255	217.1	222.72	210.38	197.78	196.457	199.788	197.347
2	0.002	255	219.69	230.35	211.13	219.393	217.64	222.042	218.544
3	0.003	255	236.31	239.65	234.9	231.257	228.731	233.11	231.882
4	0.004	255	236.24	247.38	241.28	231.787	228.416	233.825	232.676
5	0.005	255	252.48	254.84	254.46	224.272	221.493	226.478	224.633

Indicates the intensity of black, indicates the intensity of yellow, indicates the intensity of purple shows, indicates the intensity of turquoise, indicates the colour combination of three colours, Shows the intensity of blue, Shows the intensity of green, Shows the intensity of red.

Optimization of vial volume and distilled water: Different masses of barium sulfate are used to optimize the volume of the vial and distilled water Medium and large by in vials with small volumes (0.001–0.005 g) range 1 and 2 ml volumes of distilled water were dispersed and photographed by the camera. Graph of purple colour intensity by mass of barium sulfate in volume 1ml (Figures 2), large (5 ml) Medium (10 ml) Distilled water in small vials (15 ml).

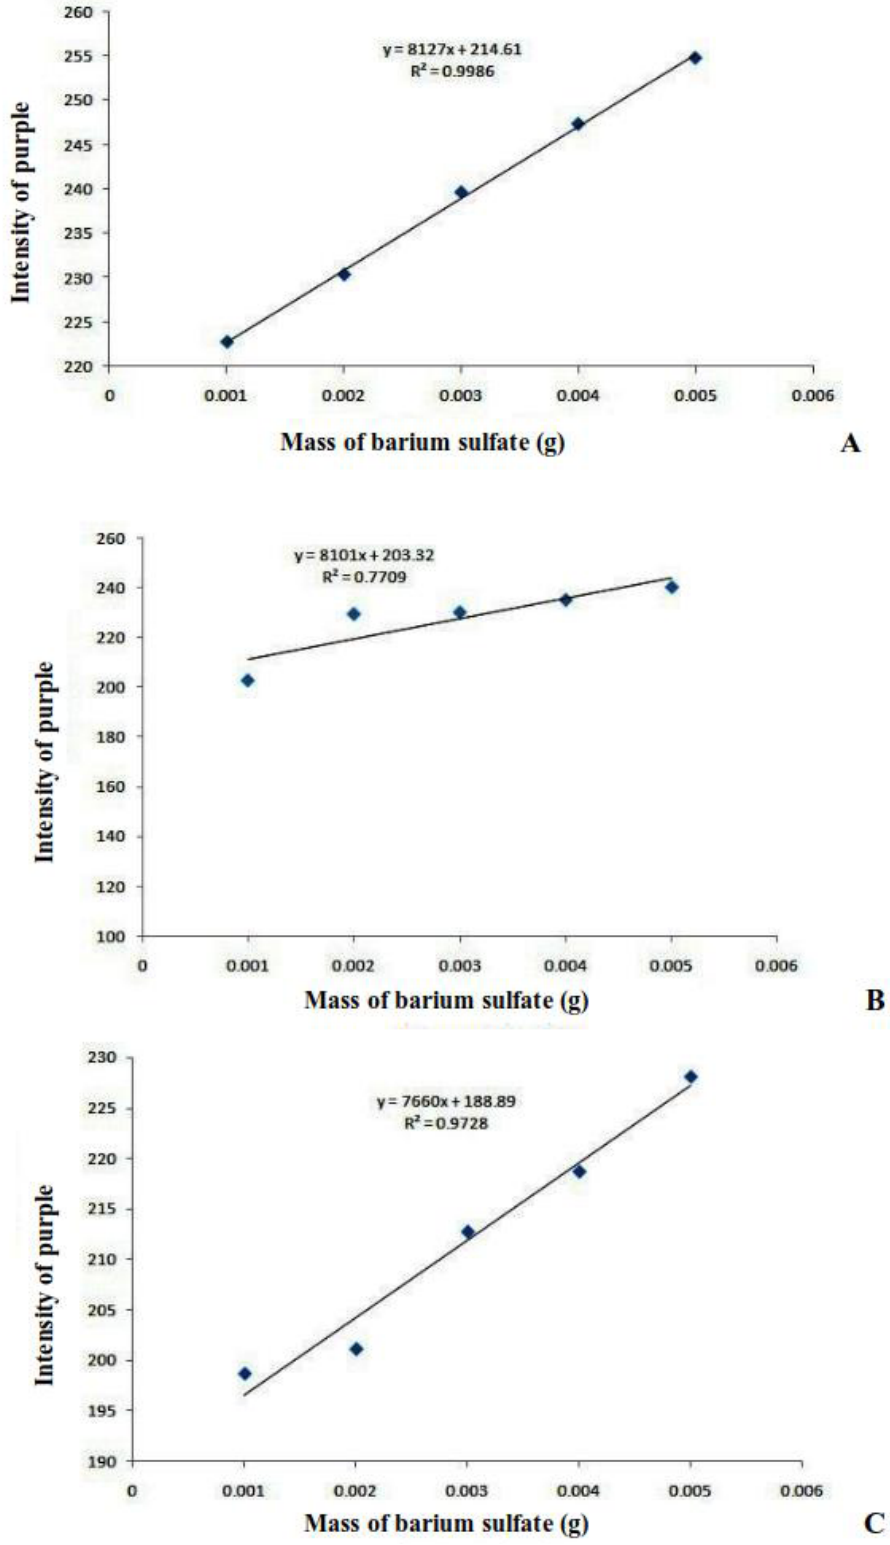

Figure 2. Image analysis results in containers (1) 5ml (2) 10ml (3) 15ml litres containing 1 ml of distilled water

Mass Optimization $BaCl_2$: Its different masses in the range 0.1- 0.5 of were investigated to optimize the weight of barium chloride. As shown in Table 2-3, the intensity of purple colour in of barium chloride was selected as the optimal mass/range and therefore became 0.1.

Table. 3-2. Results related to the change of purple color intensity with the change of barium chloride mass. 50 ml of Samples containing sulfate ions: 45 mg/L

Barium chloride mass (g)	0.1	0.2	0.3	0.4	0.5
Intensity of purple	164.81	164.38	164.84	165.77	165.45

Optimization of used lamps: Because purple dye has the highest sensitivity to measure sulfate green and blue at intervals of ‹ white ‹ to optimize the lamp used by different types such as yellow 10 cm and close 5 cm were examined. Results in (Figures 3) blue is shown at a distance of 5 cm (Figure 4, 5,6). As can be seen, has a wider range of color intensity change and uniformity with changing the volume of barium chloride is. As a result, use a blue lamp at a distance of 5 cm for further measurements took.

Disturbing ions: To evaluate the applicability of the method in real samples, different ions such as aluminium (Al^{+3}) Cobalt (Co^{+2}), copper (Cu^{+2}), in a solution containing sulfate ions at a concentration of 1000 mg/L were reduced by barium chloride to 1000 mg/L. The titration curves in Figures 7 to 8, 9 are shown. Also, the percentage of relative error of the disturbing ions mentioned in Table 3-3 shows that a very good percentage of relative error is observed in most cases.

Table 3-3. Results of disturbance ion analysis in the measurement of sulfate ions. Sulfate ion concentration 35 mg/L and the concentration of disturbing ions is 200 mg/L

Disturbing ions	The color intensity in the absence of disturbing ions	The color intensity in the presence of disturbing ions	Relative error percentage
Al^{+3}	158.39	168.83	6.6
Cu^{+2}	141.3	136.52	3.4-
Ca^{+2}	179.26	169.83	5.3-

Titration Method: In this method, first, the sample is titrated with barium chloride and through the volume of the endpoint of sulfate concentration in the sample we calculate.

River Water: To measure the sulfate ion, the titration method was used, the diagram of which is shown in Figure 10 is the amount of sulfate obtained/ shown. Given that the final volume is 0.70 it is 37 mg/L, which is in very good agreement with the actual amount (38 mg/L)

Mineral Water: Figure 11 Spike mineral water titration curve with a specified amount of sulfate (500 mg/L) shows the endpoint in volume 0.74. The concentration of sulfate in the mineral water sample is 30 mg/L, which is compared to the amount Real (31 mg/L) is in great agreement.

Water City: Figure 12 shows the spiked titration curves of city water. Given that the point is the amount of sulfate obtained in this method is 76 mg/L final 0.78 ml. Which is in good agreement with its actual amount (80 mg/L).

Conclusion

In this project, a new processing-based method has been used to measure sulfate anions in aqueous samples. By diluting different masses of barium sulfate in distilled water, it was found that changes in the intensity of purple color show the greatest sensitivity and was selected as the optimal color. By optimizing various parameters such as vial volume and distilled water, barium chloride mass and type and distance of the lamp, it was determined that the calibration curve is in the range of 5-75 mg/L linear. One of the main advantages of this method is that it does not require advanced devices, and since photography is done using a simple smartphone camera, it makes the application of this method easy and low cost. Also, the effect of disturbance study of other ions showed that only disturbing species are measured in fluoride and carbonate ions. Also, this method was used to measure barium sulfate and also sulfate anion in city water samples, and mineral water by standardization method and sediment titration.

Mammogenesis Effect of Hot Aqueous Extract of *Mentha spicata* Leaves on Mammary Tissue of Ovariectimized Rabbits

Sinaa Jaboury Al-Bazii[1], Ashwaq Kadhem Obeid[2], Rana Majeed Hameed[3]

[1]Assistant Professor, Department of Anatomy, Medicine College, Kerbala University, Kerbala, Iraq, [2]Assistant Professor, Department of Biology, Education College for Pure Sciences, Kerbala University, Kerbala, Iraq, [3]Assistant Professor, Department of Biochemistry, Medicine College, Kerbala University, Kerbala, Iraq

Abstract

Background: Plants are highly rich in phytochemicals being used to treat various conditions, and a rich source of polyphenols is Spearmint (Mentha spicata L). Such polyphenols have demonstrated multiple bioactivities. This study aims to investigate the effects of the intake of hot-aqueous extracts of spearmint leaves on mammary gland development and growth

Method: Thirty six female rabbits were divided into two main groups (18 rabbits/group): (virgin and lactating). Each group was further subdivided into three subgroups (Control, Ovariectomized (OVX) and Spearmint, (6 rabbits/group).All three groups tissues were examined for histological, histochemical and biochemical enzymatic analysis.

Result: Spearmint-treated ovariectimized virgin animals demonstrated an increase in the size of lobules that affected the alveolar bud. In the ovariectimized lactating group treated with spearmint, it was shown that the lobules were enlarged and produced more branching alveoli. The stain (PAS) and ALP showed positive reaction in the spearmint group treated with lactation.

Conclusion: The hot methanol extract of the spearmint Mentha spicata leaves have a beneficial effect on mammary gland growth and development.

Keywords: *Mentha spicata, Ovariectomy, mammary gland virgin, lactating,rabbit.*

Introduction

The mammary glands are complex tubuloalveolar glands which main function is to produce and secrete milk, it plays a major role in human nutrition either through oral feeding or via the food industry[1]. Mother's milk plays an significant role in neonatal survival, proper development and growth[2]. Mammary glands begin to develop in females at puberty and achieve maximum functional status after pregnancy. Ovarian steroids (estradiol and progesterone) play a crucial role as regulators of the different stages of mammogenesis and mammalian development[3]. Menopause is defined as the point in time after consecutive months of amenorrhea and refers to changes occurring in the hypothalamic-pituitary-ovarian axis [4].

Many females actively looking for alternative menopausal medications such as herbal nutritional supplements in attempting for reliefng the weakness, depression anxiety, extreme fatigue, joint pain and insomnia[5]. Herbal plants are an important source of herbal care and often form the basis of indigenous or traditional healing systems, which are still commonly used by the majority of populations in many countries[6,7]. The Lamiaceae family of Mentha is widely distributed in Europe, Asia, Africa, Australia and North America[8,9]. Extracts of this genus are traditionally used foods and

Assistant Professor, Department of Anatomy, Medicine College, Kerbala University, Kerbala, Iraq
e-mail: sinajabouri@gmail.com

are highly valued due to the presence of large amounts of antioxidant such as phenolic bioactive compounds[10]. Bazii *et al*, 2013 showed that the *Mentha spicata* leaves have mammagens activity without any toxicityeffect[11], Probably, it is because of the anti-androgen spearmint action, which increased serum oestrogen levels, luteinizing hormone (LH) and follicle stimulating hormone (FSH)[12,13]. Accordingly, The aim was to shed light on the stimulating ability of spearmint in the mammary tissue of ovariectimised rabbits.

Material and Method

Animals preparation: Thirty-six healthy virgin and lactating female rabbits from the ages of approximately 5-12 months old were used. The animals were housed 4/cage in a facility with a constant temperature of 22°C with consistent humidity and 12/12 hours light/dark cycle in Animal Housing Department/vet. Collage/ Karbala University. The rabbits were fed on green vegetables and tab water ad libitum. All female rabbits were divided into two main groups (18 rabbits/group): The G1 group contained the virgin rats. While the G2 group examined the lactating rabbits. Each group was further divided into three subgroups (6 rabbits per sub group):The control group was intubated tap water orally while the bilateral ovariectomy group were intubated orally with 5.25 ml/kg b.w [14], serving as spearmint group for the duration of one month.

Preparation of the hot Aqueous Extracts: Spearmint leaves had been bought from the local market. Soaking method was used to produce plant extracts[15].

Surgical operation: After routine preparation of the site of operation (midline region), the general anesthesia was induced with diazepam in dose 1mg/kg b.w. after 10 minutes as a preanesthetic. Then xylazine was injected in doses of 10 mg/kg b.w. while ketamine, in 50 mg/ kg b.w. Both injections were performed intramuscularly according to open operation [16]

Tissue sampling and processing: The tissue samples obtained from the mammary gland of all rabbits from both groups were anesthetized with chloroform directly after being sacrificed. Routinally stained histological slides with hematoxyl, eosin stain and the Periodic Acid Schiffs Stain Was achieved through the procedure that described by Lawrence [17]

Alkaline Phosphatase Activity: Most mammary gland ALPs are in the myoepithelial cells, Epithelial secretory cells have low levels of ALP activity, which could play a role in milk secretion. This enzyme relates to mammaryfunction and may be concerned with nutrient transport. Therefore the activity of ALP was measured to demonstrate the alkaline phosphatase activity based on modified procedure described by[18.]

Results

Histological Studies:

Virgin Rabbits: In the Control group Haematoxyln-eosin stained tissues illustrated the lobules were packed with alveolar buds and intralobular ducts. While small lobules scattered among huge amount of adipose tissue were examined in the OXV group. In Spearmint group there was an increase in the size of lobules when compared with the OVX group Fig.1(a,b and c) respectively.

Lactating Rabbits: The histological examination in OXV group showed an increase in the lobular size with corresponding decrease in the adipose tissue. The alveoli and ducts were dilated and filled with secretory products. Figure 2band2c illustrated thespearmint group which showcased that lobules were increased in size, packed with branching alveoli and filled with secretory products. In the OXV and Spearmint groupsgreatly, narrow lobules containing little branching and non-dilated alveoli in compared withControl group(Fig.2a).

Periodic Acid Schiffs Staining: Staining with Periodic Acid Schiffs (PAS) stain gives identical features to those stained with Hematoxylin and Eosin stain, these results included:

Virgin Rabbits: The histological examination of mammary gland sections in control, OXV and Spearmint groups showed negative reaction to the PAS stain as illustrated in (Fig.3a, b, and c)respectively.

Lactating Rabbits: Positive reactions to the PAS stain were noticed in the histological sections of mammary gland that were obtained from the Control group. Similar results were reported in the mammary tissue of lactating rabbits treated with OXV and Spearmint as seen in (Fig.4a, b, and c)respectively.

Alkaline Phosphatase:

Virgin Rabbits: Mammary tissue sections of rabbits treated with hot aqueous extract of Spearmint, OXV and Control group were showed negative expression of

ALP activity around the intralobular ducts (i.e. positive activity of ALP in the myoepithelial cells) as illustrate on (Fig.5a, b and c).

Lactating Rabbits: Microscopic examination to sections of mammary gland of rabbits in spearmint showed moderate activity of ALP of the myoepithelial cell (Fig.6c). On the other hand, the mammary tissue of lactating rabbits of control group showed more dense activity to ALP (Fig.6a) compared to OXV group which showed weak expression (Fig.6b).

Discussion

Histological results showed a decrease in the size of the lobules and alveoli of mammary gland with less dilation in OVX virgin rabbits when compared to the sham group, this suggested that synthesize estrogen by the ovaries was very low in concentration of OVX animals due to the development of the mammary gland during the adult period[19]. Ovariectomized lactating rabbits showed decreased in the mammary parenchyma with an increase in the connective tissue. In contrast, the alveoli were rudimentary in ovariectomized animals when compared with the Control group, that might be because the estrogen produced by ovaries is very low in levels of ovariectomy rabbits[20]. Ovariectomy showed an impact on epithelial cell and induced a deep morphological disorganization of the mammary tissue[19]. The current study revealed that the intubation of female rabbits of all groups with 5.25 ml/kg b.w of hot aqueous extract of spearmint caused expansion in the size of lobules and number of alveoli, especially during lactation stages when compared with OXV group. These results revealed that the spearmint treated group had the ability to induce mammogenesis in virgin and lactating rabbits. Some studies concluded that in addition to estrogen and progesterone hormones, entire differentiation of the rabbit mammary gland development requires additional action of prolactin. The terminal stage of mammary gland development, lobuloalveolar growth is regulated by the production of prolactin hormone[21,22]. During early pregnancythe prolactin regulation the stimulation of ovarian progesterone in addition to assist in maintaining the required levels of progesterone [23,24]. Prolactin and progesterone up-regulation of PR expression suggest that those hormones can interact synergistically to regulate the alveolar growth. The prolactin stimulation compounds may raise the prolactin secretion via dropping levels of prolactin inhibitory factors[25,26], such compounds are found in spearmint. Carvon is one of the compounds that resembles the chemical structure of dopamine (prolactin inhibitory compound) and competes with dopamine receptors which leads to prolactin secretion[27,28]. The results also revealed that spearmint had estrogen like effects. The estrogen hormone play important role in Proliferation of luminal epithelium, their differentiation and survivalin mammary glandduring pregnancy, lactation and virgin stages through its receptor ERα[29]. In addition, progesterone receptor and cycline D1 are the downstream estrogen receptors. The progesterone receptor regulates the cyclin D_1 that has positive

feedback on is required for transcriptional activity of ERα in mammary gland development. On other hand, the progesterone receptor required for epithelial differentiation and morphogenesis[29,30].

Moreover, the mammary stem cell might be ER positive[31]. This cell has the capability to produce whole mammary gland tissues; where the primary mammary stem cell leads by different processes to produce different cells found in the mammary parnchyma[32,33]. Accordingly, when estrogen hormones binded to estrogen receptor in stem cells of mammary gland that will induction the growth in mammary tissue constituent[34.]. The proliferation effect of spearmint in mammary gland tissue may result from the ability of spearmint to decline the level of androgen hormone that causes suppression in growth of mammary gland with increase in estrogen hormone level[35]. Additionally, the hyperactivity of the experimental mammary gland in this study proposed to be due to biotransformation of saponin compound into sex hormones, where spearmint is capable of inducing[36]. The ALP enzyme plays an important role in the transport mechanism of phosphate, cell division, phosphorylation and dephosphorylation of other substances[37],the mammary gland tissue of rabbits treated with spearmint hot aqueous extract seems to be strongly activated by the ALP enzymes in all physiological stages. This finding supported by the growth and development of mammary glands which attributed to an increase in the proliferation of mammary gland cells in rabbits[22].

Conclusion

The hot aqueous extracts of spearmint Mentha spicata leaves have Mammogenesis effect of mammary glands during virgin and lactating stages in ovariectomized rabbits.

Abstract

After delivery uterine function usually exposed by bacterial contamination of the uterine lumen. This study was conducted on 21 cows of Holstein-Friesian breed, aged between 4-6 years, with parity of 2-4 times suffered from postpartum metritis. The disease diagnosed according to the clinical symptoms and vaginal examination. Animals divided into 3 equal groups. 1st group treated with $PGF_2\alpha$ 20 mg/im., 2nd group treated with 2% lugol's Iodine Intra Uterine, while the 3rd group treated with lotagen 2% I.U. The results showed that the treatment with $PGF_2\alpha$ give high efficacy rate 100% (7/7) than that with lugol's Iodine 57% (4/7) and with lotagen 71% (5/7). There was a significant difference ($P \leq 0.05$) in treatment with $PGF_2\alpha$ as compared with other treatments, it was concluded from this study that $PGF_2\alpha$ give the best results in postpartum metritis treatment.

Keywords: *Postpartum metritis, dairy cows, $PGF_2\alpha$ lugol's Iodine, lotagen.*

Introduction

Metritis defined as inflammation of whole layers of the uterus. It is most commonly occurres in the postpartum period of dairy cattle within 10-14 days after parturition [(1)]. Postpartum (pp.) contamination of the uterus with bacteria regarded as a causative criterion for infection [(2,3)], It causes a great economical loss to the farmers especially in multiparous dairy cattle as a results of decrease of reproductive performance due to delayed uterine involution, increase calving interval, open days, number of service per conception [(4–6)]. There are many factors makes the cows more susceptible to metritis. These factors includes; Immune response, genetic factors, management factors, infections factors and nutritional and metabolic factors [(5)] There are several method to treat postpartum metritis reported by several authors [(7–15)]. Postpartum metritis is commonly treated with hormones or antibiotics or antiseptics alone or in combination[(4,10,12)]. The hormonal treatments include; $PGF_2\alpha$, oxytocin and oestrogens[(9,12,13)]. The antiseptics includes lugol's Iodine solution, Bovidine and lotagen[(12,13,16)]. The antibiotic therapy includes; oxytetracycline, gentamycin, chloramphenicol and penicillin- streptomycin[(4,12,13,16)]. The study was aimed to investigate the response of treatment of postpartum metritis in dairy cattle with the $PGF_2\alpha$, Lugol's Iodine and lotagen.

Materials and Method

The study was conducted on 21 cows of Holstein-Friesian breed aged between 4-6 years with parity of 2-4 in numbers, suffered from postpartum metritis, presented in the farm of coll. Vet. Med., Baghdad University. The postpartum metritis was diagnosed according to the clinical signs (mucopurulent discharge expelled through vagina) and vaginal speculum. Animals were divided into three equal groups. The 1st group (T_1) were treated with prostaglandin $PGF_2\alpha$ (Lutalyase, Upjohn co. USA). 20mg/im. The 2nd group (T_2) were treated with 50ml Lugol's Iodine 2% (stock solution; 8 gm pot. Iodied; 4 gm crystal Iodine in 100 ml distal water) Intra Uterine (I.U.), three times per a week (one day and another). The 3rd group (T3) were treated with 2% Lotagen (Bioveta, a. s., Ukrainian,) I.U., three times per a week (one day and another). Animal showed normal estrus without vaginal discharge within 10-14 days after the treatment

regarded as positive response. Statistical analysis using chi-square.

Results and Discussion

The main goal of treatment of postpartum metritis was to eliminate bacterial infection, stimulate uterine defense mechanism and increase hyperemia of the uterus. Also treated drug showed increase uterine muscle contraction to clear and evacuate uterine content[12–14,16]. The pharmacological therapy should not cause adulteration of milk and having antibacterial activity and do not cause a resistance[12,13]. Table -1 showed the effect of different method to treat postpartum metritis and the response and efficacy of each medication. There was a significant different (P≤0.05) between treated groups in the response to the treatment. $PGF_2\alpha$ which used in T_1 showed an efficacy of 100% (7/7) while the treatment with Lugol's Iodine and Lotagen showed an efficacy of 57.1% (4/7) and 71.1% (5/7) for T_2 and T_3 respectively. The higher response obtained with $PGF_2\alpha$ in treated animals might be due to the fact that $PGF_2\alpha$ cause luteolysis to the corpus luteum that leads to decrease progesterone which inhibits uterine defense mechanism (UDM), oestrogen secretion that stimulate UDM., and $PGF_2\alpha$ stimulate myometrial contraction that evacuate the uterine lumen from lochia, blood clot, cellular debris, exudate, pus and remnant of fetal membranes. Also $PGF_2\alpha$ induce phagocytosis by attraction of leukocytes[12,13,17]. Similar observation has been made by several workers[12,14,16,18]. It has been reported that the $PGF_2\alpha$ the most effective drug for metritis[19], while others showed no improvement of the subclinical metritis[20,21]. It has been observed that administration of 25 mg/im of Dinoprost (synthetic $PGF_2\alpha$) had an effect on reduction of the size of the uterus[22]. The low response in T_1 and T_2 which treated with lugol's Iodine and Lotagen respectively it might be due to that intrauterine infusions treated with these antiseptics leads to irritation and necrosis of endometrial wall and may cause damages to the endometrial glands. Similar results have been reported by many authors [12,13,16,23], or it might cause inflammatory reactions that leads to fibrosis of endometrium[23]. It has been observed that the use of lugol's Iodine intrauterine have no beneficial effect on reproductive performance in cows with reproductive problems[24]. It has been explained that the use of 1% lugol's Iodine solution intrauterine in cows showed improvement against uterine infection due to its bactericidal and the slight hyperemia to the uterine mucosa that increased blood circulation and enhance the uterine defense mechanism[23,25]. Also the chemotherapeutic with intrauterine infusion with chemicals might lead to unwanted effects to the uterus and damage of the oviduct may be occurred[16].

Table 1. Effect of different treatments on pp. metritis in dairy cattle.

Type of treatment	No. of animals	Positive response	Efficacy %
(T_1) $PGF_2\alpha$ 20mg I.M.	7	7	100% a
(T_2) Lugol's Iodine 5%I.U.	7	4	57.1% b
(T3) Lotagen 2% I.U.	7	5	71.4 %b
Total	**21**	**-**	**76.19**

Different small manuscripts mean significant difference at (p≤0.05).

Conclusion

It could be concluded from this study that $PGF_2\alpha$ injection have a beneficial effect on treatment of postpartum metritis.

Human Rights and Legal Protection of Persons with Disabilities in Aviation Industry in Indonesia

Adya Paramita Prabandari[1], Elfia Farida[1], Rahayu[1]

[1]*Lecturer at Diponegoro University, Indonesia*

Abstract

Various matters relating to persons with disabilities are often overlooked and often lead to discrimination against them in various fields of life. Likewise, in Indonesia there is often discrimination against persons with disabilities in various aspects of life, including in aviation. For this reason, it is very important to analyze the protection of the rights of persons with disabilities in Indonesian aviation. The method used is a normative juridical method using a statute approach and conceptual approach to analyze secondary data obtained through library research. The government as a duty bearer is fully responsible for ensuring good and accessible service quality and providing facilities for persons with disabilities in flight. Likewise, airport and airline operators as air transport service providers should have SOPs of services that are in accordance with Government policy in order to provide maximum and equal services for persons with disabilities, as a form of protection for the rights possessed by persons with disabilities.

Keywords: *Protection, rights of disabilities, aviation, Indonesia.*

Introduction

Globalization is a very rapid and fundamental change in the structure of human life that has occurred since the beginning of the 21st century, and brings enormous changes in various fields, including the field of transportation. The development of transportation technology is very rapid, where the current movement of people, capital, and goods, both between countries and between regions in various parts of the world takes place more quickly with the support of aircraft transportation modes. Modes of aircraft transportation are not only used by people with normal conditions, but are also carried out by people who have different abilities and conditions from normal and reasonable of people with disabilities. In Indonesia, problems relating to persons with disabilities are often ignored and often lead to discrimination against them in various fields of life. Likewise in civil aviation, where there are several times discrimination against persons with disabilities carried out by airlines, even the case reaches the legal domain[1].

In aviation industry, there are some incidences discriminating persons with disabilities in flight, although WHO has stated that disability is a human condition, and is not a type/form of disease[2]. In addition, another form of discrimination carried out by airlines against persons with disabilities is the obligation to bring a companion for persons with visual impairments and other persons with disabilities, due to the notion that aircraft are not directly accessible for people with mobility disabilities[3]. Persons with disabilities, as members of the community and Indonesian citizens, truly have the same position, rights and obligations as other Indonesian citizens, although it cannot be denied that persons with disabilities have physical and/or mental disorders that can interfere or constitute obstacles to carrying out activities like people without disabilities. This paper explores the protection of persons with disabilities in Indonesian aviation by using human rights perspective.

Research Method

The research method used in this paper is a normative juridical method[4], using a statute approach and

conceptual approach[5]. The data used are secondary data obtained through library research. The data is processed and analyzed using qualitative analysis method and then presented in the form of systematic writing.

The Perspectives of Human Rights of People with Disabilities: Article 1 of the Convention on the Rights of Persons with Disabilites describes that persons with disabilities include those who have long-term physical, mental, intellectual or sensory impairments which in interaction with various barriers may hinder their full and effective participation in society on an equal basis with others. Meanwhile, according to the International Classification of Functioning, Disability, and Health, disability is defined as problems in the body function or structure such as a significant deviation or loss, a reduction, an increase, or an excess[6]. People with disabilities can be classified some, which are mobility and physical impairments, spinal cord disability, acquired brain injury, vision disability, hearing disability, cognitive or learning disabilities, psychological disorders and invisible disabilities.

Human rights are rights possessed by humans, solely because he is human. Humans have human rights not because they are given to them by the community or based on positive law, but merely based on their dignity as human beings[7,8]. Human rights are fundamental rights in human beings. The institutionalization of human rights began with the enactment of various human rights instruments in various countries in the form of laws and declarative instruments containing provisions on human rights, including: Bill of Rights) in England in 1688; Declaration of Independence in 1776; and Declaration des Droits de l'homme et du Citoyen in France in 1789[9]. These instruments are the starting point for the discussion of human rights instruments so that they finally produce the Universal Declaration of Human Rights (UDHR) which is a document of international recognition of human rights prepared by the UN Human Rights Commission. This declaration was accepted by United Nations General Assembly Resolution Number: 217A (III) on 10 December 1948.

In the First Paragraph of the Opening of the UDHR it was stated that while recognition of the inherent dignity and of the equal and inalienable rights of all members of the human family is the foundation of freedom, justice and peace in the world. This is an affirmation that human rights are the basis of freedom, justice and peace in the world. Furthermore, Article 3 of the UDHR states that everyone has the right to life, liberty and security of person. The human rights inherent in every human being affirmed in Article 3 of the UDHR are of course also inherent in persons with disabilities. As part of humanity and having the same human rights as other people who do not have barriers and disabilities, an important milestone in the recognition, respect and protection of human rights is the ratification of the Convention on the Rights of Persons with Disabilities (CRPD) on December 13 2006 in the 61st Session of the UN General Assembly with resolution A/RES/61/106. This convention came into force on May 3, 2008. CRPD is a convention based on the concept of modern equality that has developed in various phases of equality law with different ideas of equality[10].

The purpose of CRPD is to promote, protect, and ensure the full and equal enjoyment of all human rights and fundamental freedoms by all persons with disabilities, and to promote respect for their inherent dignity. States are required to report regularly about the implementation of the rights of disabled people to enable the Committee to monitor the implementation of the Convention from time to time[11]. For this reason, the States Parties to this convention have obligations which include guarantee and promote the full realization of all human rights and fundamental freedoms for all persons with disabilities without discrimination in any form that is based on disability; prohibit all discrimination based on disability and ensure equal and effective legal protection for persons with disabilities against discrimination based on any reason; adopt policies that are immediate, effective, and appropriate to increase awareness of the whole community, including at the family level, regarding persons with disabilities, and to maintain respect for the rights and dignity of persons with disabilities; and to combat stereotypes, prejudices, and harmful practices concerning persons with disabilities, including those based on gender and age, in all aspects of life; take appropriate policies to ensure access for persons with disabilities, on an equal basis with others, to the physical environment, transportation of information and communication, including information and communication technology and systems, and to other facilities and services that are open or available to the public, both in urban and rural areas.

Legal Protection of Persons with Disabilities in Indonesian Regulations: In human rights law, the State or Government has a duty bearer covering 3 (three) obligations, that are obligation to respect, obligation

to fulfill and obligation to Protect[9]. With regard to human rights owned by persons with disabilities and the Government of Indonesia as a duty bearer, the Government of Indonesia on February 28, 1997 has enacted Law No. 4 of 1997 concerning Disabled Persons, which among others regulates the rights and obligations of persons with disabilities, equality of opportunities owned by persons with disabilities in every aspect of life, as well as criminal provisions for offenders and administrative sanctions.

Along with the development of the times and the evolution of thought in society, especially in medicine, in the international world the term and concept of impairment, then changed to disability, which is considered more complex and comprehensive than impairment[12]. Furthermore, impairment is instead a component of disability, in the Disability Component Categorization such as impairment, limited activity and participation, individual characteristics and environment and individual effects[13,12]. Impairment is only one component of the four categories of disability components. In this case, the social environment is also a component that plays a role in creating social and cultural barriers for persons with disabilities to be able to live equally as members of the community. The community also has the responsibility to remove these barriers so that the mobility of persons with disabilities becomes more spacious and more free to be able to access and utilize the potential resources around them for the development of their potential to be able to realize their independence.

Changes in the mindset and concept of impairment to use the term "disability" in the international community inevitably lead to changes in the policy orientation of the Government of Indonesia. This was proven by the participation of Indonesia as one of the signatory States that signed the Convention on the Rights of Persons with Disabilities on March 30, 2007, and then ratified it with Law Number 19 of 2011 concerning Ratification of the Convention on the Rights of Persons with Disabilities which took effect on November 10, 2011. This was followed by the enactment of Law No. 8 of 2016 concerning Disabled Persons, which replaced Law No. 4 of 1997 concerning Disabled People because it no longer complies with the paradigm of the needs of persons with disabilities. In addition, the Government also includes elements of protection for persons with disabilities in various laws and regulations in Indonesia, including those relating to aviation.

In various laws and regulations regarding aviation and air transportation, the Government of Indonesia has included rules regarding services and handling for persons with disabilities. First, Law No. 1 of 2009 concerning Aviation stated that the holder of a commercial air transportation business permit is obliged to serve prospective passengers fairly without discrimination on the basis of ethnicity, religion, race, class, and economic and social status. This article regulates the right of persons with disabilities to receive services in the form of special treatment and facilities from commercial air transport businesses. Services in the form of special treatment and facilities include at least to provide priority to additional seats; provision of facilities for boarding and alighting from aircraft and facilities while in the aircraft; the availability of personnel who can communicate with people with disabilities; and the availability of manuals on flight safety and security for aircraft passengers and other facilities that can be understood by persons with disabilities. Additional treatment and facilities are free of charge. Services in the form of special treatment and facilities for passengers with disabilities or sick people are intended so that they can also enjoy proper transportation services. Moreover, Article 239 stipulates that persons with disabilities are entitled to receive services in the form of special treatment and facilities from an airport business entity or airport operating unit.

Second, the protection is specified in Minister of Transportation Regulation No. PM 98 of 2017 concerning Accessibility for Persons with Disabilities and Sick People in Transportation Facilities and Infrastructure. The Regulation regulates that public transportation service providers are required to provide accessible service facilities and infrastructure for service users with special needs such as assistive devices to move up and down from and to transportation facilities, audio/visual information about travel that is easily accessible, priority seating and easily accessible toilets, and the provision of specific signs or instructions in the service area at the means of transportation. Transportation service providers are also required to provide information centers and personnel equipped with relevant training in order to help service users with special needs. Minister of Transportation Regulation No. 38 of 2015 concerning Domestic Air Transport Passenger Service Standards regulates to persons with disabilities that passengers with special needs are passengers because of their physical condition and/or special requests for

passengers who need special facilities and treatment, such as persons with disabilities, elderly people, children, pregnant women and sick people. The air transport service providers in providing services for air transport passengers must have a reference in the form of air transport passenger service standards. The service standard starts at the time of entering the airport gate until the passenger exits from the airport gate after the flight. Domestic air passenger service standards at airports must contain the following components: safety services; security services; reliability service; comfort service; convenience services; and equality services. Even indicators and benchmarks for the fulfillment of the equality service components have been provided in Attachment I to this Ministerial Regulation. The service standards for domestic air transport passengers while on board aircraft that contain the same components as the domestic air passenger service standard components at airports. The air transport passenger service provider is required to prepare a standard service document in accordance with the specified components, and the document must be approved by the Director General of Civil Aviation.

In addition, Minister of Transportation Regulation No. 77 of 2015 concerning Airport Facility Standardization and Certification regarding passengers with special needs regulated in Article 9, stated that airport facilities for passengers with special needs must be able to provide services to passengers with special needs with or without the help of others, safely and comfortably. However, there is still a variety of discrimination against persons with disabilities in Indonesian civil aviation and other public sectors.[14,15] This is often caused by a lack of socialization and information received and understood, both by airport officials and airline staff (ground-staff and cabin crew), regarding the rules of non-discriminatory service standards for persons with disabilities, both rules in statutory regulations which are government policies, as well as airline service standards issued by each airline as an air transport business entity.

Conclusion

The Indonesian Constitution provides for the recognition, guarantees and protection of the human rights of all its citizens, including persons with disabilities who are also human beings who have fundamental and human rights like other humans in general who are inherent from their birth and cannot be taken away or violated by anyone. Therefore, the Government of Indonesia as a duty bearer has the obligation and responsibility to fulfill the human rights inherent in persons with disabilities. Various government policies, especially in the field of aviation, have also accommodated and provided special rules regarding matters relating to persons with disabilities. For example, standardization of services and treatment of persons with disabilities. However, in practice it cannot be denied that there are still many violations and discrimination against people with disabilities. Existing regulations are still not very well known to all airport operators and air transport business entities (airlines), so they have not been able to apply effectively in practice. Therefore, the government should be the duty bearer who is authorized to issue regulations, fully responsible for ensuring good and accessible service quality and providing facilities for persons with disabilities. Likewise, airport and airline operators as air transport service providers should have SOPs of services that are in accordance with Government policies in order to provide maximum and equal services for persons with disabilities, as a form of protection for the rights possessed by persons with disabilities.

Preparation and Identification of Metal Ions Complexes for 4-(P-Phenyl azo sulfonic acid)-1-Naphthol Dye

Haider S. Mohammed[1], Shaimaa H. Mallah[2]

[1]Lecturer, [2]Ass. Lecturer, Department of Chemistry, College of Science, Al Muthanna University, Al Samawa City-66001, Iraq

Abstract

The organic reagent, 4-(p-phenyl azo sulfonic acid)-1-naphthol), was found to be sensitive and selective reagent for the spectrophotometric determination of trace amounts of Cobalt and Nickle. The prepared complexes and azo reagent were characterized using FT-IR and UV-Vis spectroscopic method. The complexes have a maximum absorption at (453) nm and (446) nm for both Cobalt (II) and Nickle (II(respectively, Beer›s law was obeyed in the range (0.5-2.5) ppm of Cobalt and molar absorptivity $\varepsilon = 3.24 \times 10^4$ L.mole^{-1}. cm^{-1}, as for Nickle, the range was (0.1-2) ppm and molar absorptivity $\varepsilon =) 0.96\times10^4$ (L.mol^{-1}.cm^{-1}. The accuracy and reproducibility of the determination method for various known amounts of cobalt (II) and Nickle (II(were tested . The results obtained are both precise (RSD was better than 1.6 %, 3 %) for both Cobalt (II) and Nickle (II(respectively and accurate (relative error was better than 1 %, 2 %) for both Cobalt (II) and Nickle (II(respectively.

Keyword: *Metal Ions Complexes, 4-(P-Phenyl azo sulfonic acid)-1- naphthol Dye.*

Introduction

Essential elements are of important in many biological functions. Metals can be found in enzymes and cofactors required for various processes [1]. Nickel is a constituent of the enzyme urease and considered to be essential to plants and some domestic animals [2]. The deficiency of nickel may lead to health risks such as bone deformities but excess nickel can cause lung cancer and cardiovascular[3]. Cobalt is an essential element for enzymatic functions in all mammals and it is part of vitamin B12, which is important in protein formation and DNA regulation[4]. Exposures to a high level of cobalt lead to serious public health problems and are responsible for several diseases in human such as asthma, pneumonia, and cardiomyopathy [5]. The consumption of large quantities of nickel and cobalt-containing products in industry inevitably leads to environmental pollution at all stages of production, recycling and disposal. Thus, the determination of trace levels of nickel and cobalt in biological and environmental samples is an important analytical task. The determination of nickel and cobalt in water samples of environmental interest in which it is found at very low concentrations requires the use of pre-concentration method coupled to spectroscopic method[6,7].

In the present study we wish to introduce this reagent as a selective reagent in spectrophotometric determination of micro amounts of cobalt (II) and nickel (II) in simple and sensitive method .

Apparatus: A Shimadzu double-bean UV-visible Spectrophotometer model UV-1650 (Japan) equipped with 1.00 cm quartz cells is used for the scanning study of absorption spectra of the complexes formed. FT.IR Absorption spectra were taken on (Test scan Shimadzu FT.IR 8000 series). Measurements of pH were made using an (Hanna, HI9811-5 pH – meter) equipped with a glass - saturated calomel combined electrode. Melting points of ligand and complexes were obtained with an electro thermal melting point apparatus. Conductivities

e-mail : haidersmohammad97@gmail.com

were measured for 10^{-3} M of complexes in DMSO at 25ºC using (Alpha digital conductivity model -800).

Standard solutions of copper(II) and Nickle (II): A stock solution of Co^{2+} and Ni^{2+} (100 ppm) were prepared by dissolving (0.0025g) of $CoCl_2.6H_2O$ and (0.0035 g) of $NiCl_2.2H_2O$ in 100 mL distilled water, other working standard solutions were prepared by simple dilution of the appropriate volume of the stock solution with distilled water .

4-(p-phenylazo sulfonic acid)-1-naphthol) solutions: 4-(p-phenylazo sulfonic acid)-1-naphthol) was synthesized and recrystallized according to the method mentioned in previous study [8] A stock solution (1×10^{-3}M) was prepared by dissolving 0.082 g of reagent in 250 mL of ethanol. More dilute solution of the reagent was prepared as required.

Preparation of complexes: The complex was prepared by stoichiometric amount from ligand in 100 mL of ethanol then added drop wise with stirring to a stoichiometric amount 2:1 for metal salt in 50 mL distilled water. The mixture was stirred at room temperature for 5 min. The pH of solution was adjusted to optimum pH then left for 24 hr. The solid product thus formed off, washed with distilled water, and recrystallized from ethanol.

General Procedure: In to a series of 10 mL calibrated flask, transfer increasing volumes of Co (II) and Ni(II) working solutions (10 µg mL^{-1}) to the range of the calibration curve, add 1.5 mL and 2.5 mL of $1x10^{-3}$ M of 4-(p-phenylazo sulfonic acid)-1-naphthol) solution for Co (II) and Ni(II) respectively . The pH (7.6,9.0) for Co (II) and Ni (II) was adjusted with dilute hydrochloric acid and sodium hydroxide solutions. The complexes formed were solubilized in water and diluted up to 10 mL with distilled water. Measure the absorbance at 446 nm for Co (II) and at 453 nm for Ni(II) complexes against a reagent blank .

Results and Discussion

Spectra photometric studies:

I-Absorption spectra: The absorption spectra for Co (II) and Ni (II) complexes with 4-(p-phenylazo sulfonic acid)-1-naphthol) against blank solution are shown in Fig. 2, 3. The maximum wavelengths of two complexes are 453nm and 446 nm, respectively.

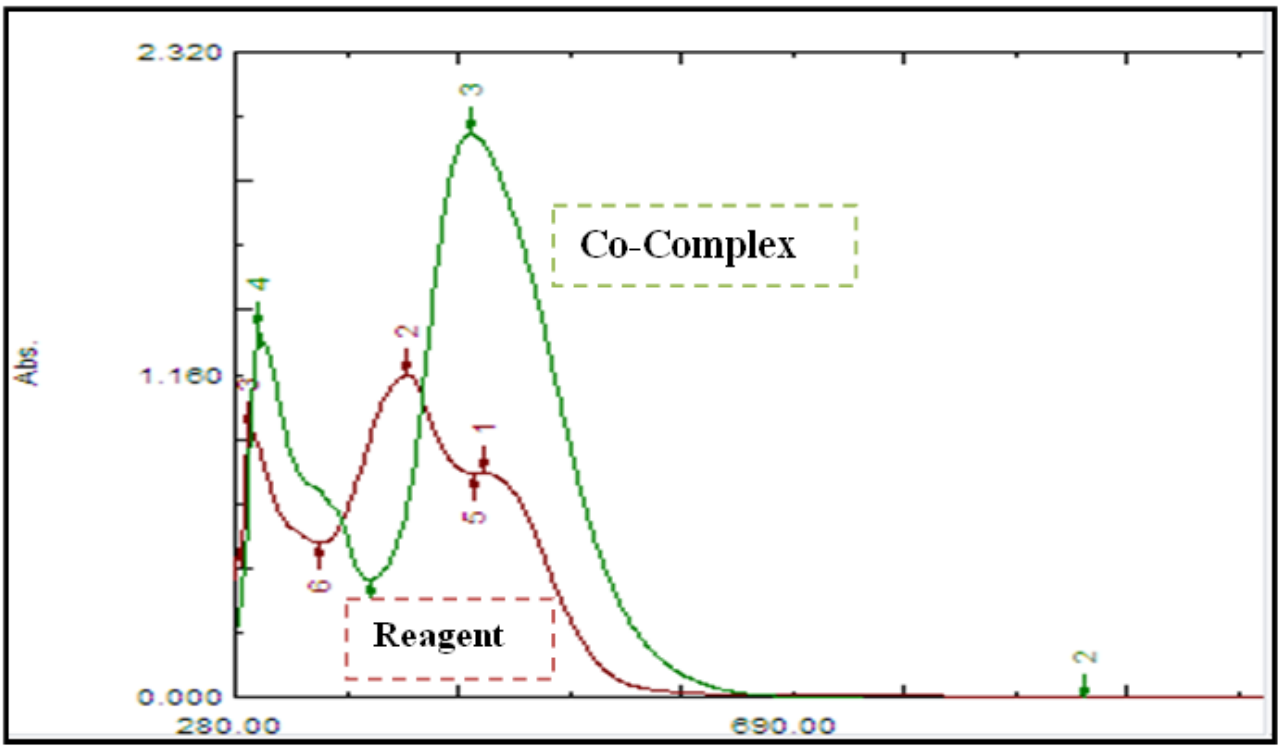

Fig. 2: Absorption spectra of [Co (II) + 4-(p-phenylazo sulfonic acid)-1-naphthol)] treated as described under procedure and against reagent solution as blank.

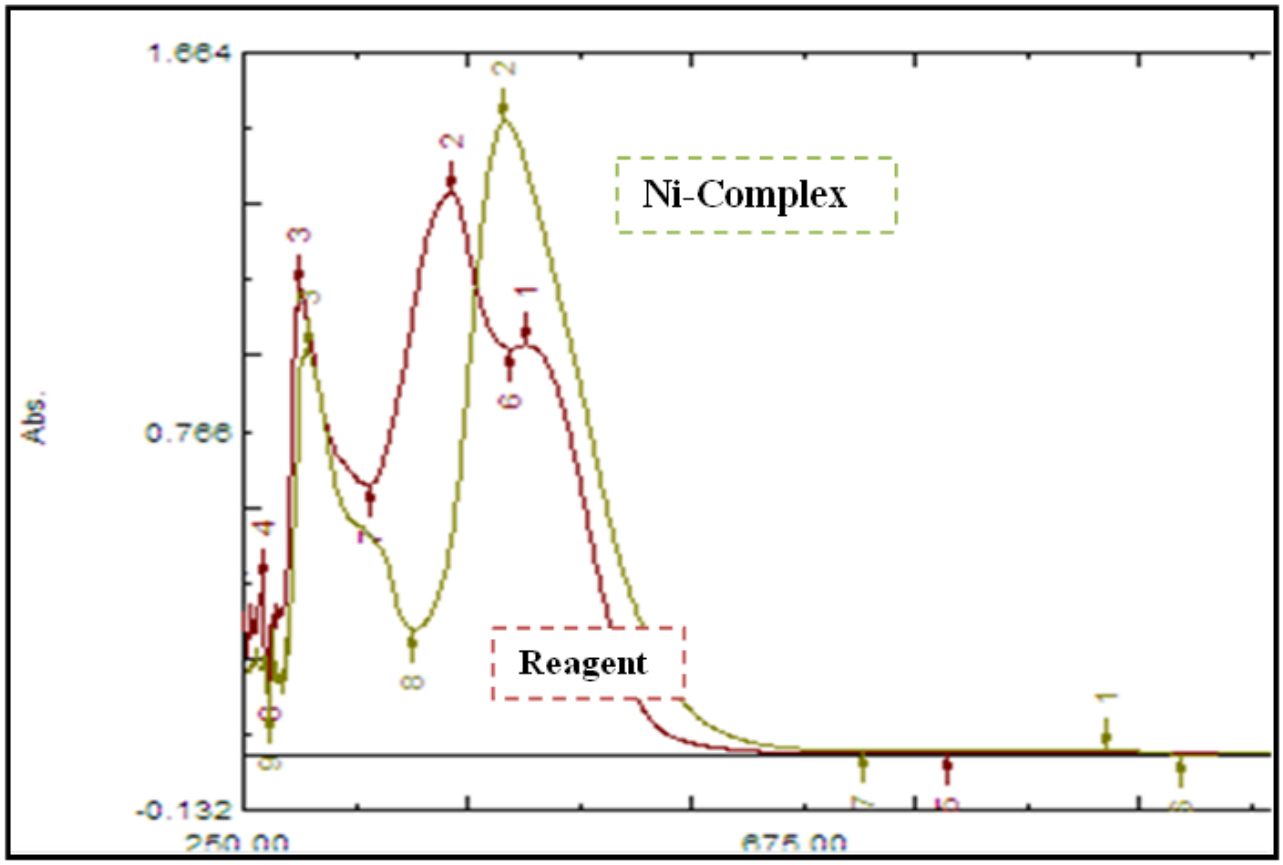

Fig. 3: Absorption spectra of [Ni (II) + 4-(p-phenylazo sulfonic acid)-1-naphthol)] treated as described under procedure and against reagent solution as blank.

II-Infrared Spectra: The FT.IR of the free ligand and its complexes with Co (II) and Ni (II) ions are given in Table.1. The IR spectrum of ligand exhibited broad band at 3437.26 cm^{-1}, has been assigned to the naphtholic OH group[9]. In the spectra of Co(II)– Complex and Ni(II)–Complex the broad weak absorption band around 3392.90 cm^{-1} and 3230.87 cm^{-1} respectively indicates the presence of water in these complexes [10].Two absorption bands are observed at 1450.52 cm^{-1} and 1384.94 cm^{-1} in the reagent spectrum,which are due to the azo group υ (N=N). These bands shifted in complexes, which suggest engagement of this group in the coordination with the metal ion [11,12]. The weak bands observed at 2968 cm^{-1} in the spectrum of reagent which are due to υ (C–H) aromatic. These bands are stable in position in both reagent and metal complexes. The appearance of new bands around (500-400) due to (M-N)[13,14].

To optimize the conditions for determination of Cobalt (II) and Nickle (II(such factors as The pH of the solution, the concentration of 4-(p-phenyl azo sulfonic acid)-1-naphthol) and composition of complexes were evaluated.

Table 1: Selected FT.IR data of reagent and it's complex with Co (II)

Compound	υ (OH)	υ (C-H) arom.	υ (N=N)	υ(M-N)
HL	3437.26 m	2968 w	1450.52 m 1384.94 s	–
[Co (L)]	3392.90 w	2968 w	1490 m 1460 s	550 w
[Ni (L)]	3230.87 w	2968 w	1500 m 1411 s	520 w

S: sharp; m: medium; w: weak

Effect of pH: The effect of pH was also studied at pH range (5 - 10) and the absorbance- pH curves for each complexes measured at certain (λmax) were plotted. Fig.(4) showed a selective pH- absorbance curves. The plateau of the curves represent the completion of the reaction and consequently represent the optimum pH.

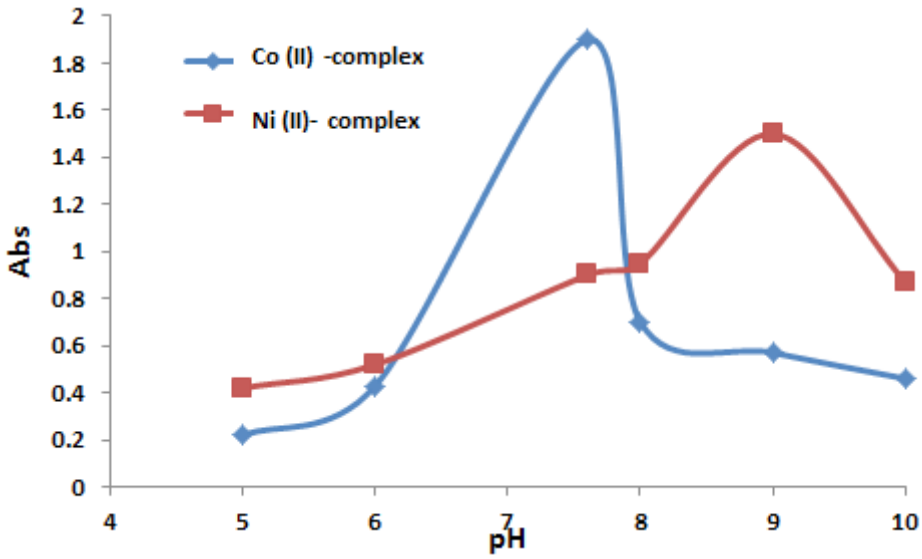

Fig. 4: Effect of PH on complex formation

Table 2: Analytical characteristics of complexes.

Characteristic	**Co (II) – complex**	**Ni (II) – complex**
Maximum Absorption peak (nm)	453	446
Beer's law validity range (ppm)	(0.5–2.5)	(0.1–2)
pH range	(6–8)	(8–10)
Sandell's sensitivity µg . cm^{-2}	0.0018	0.0062
Molar absorptivity (L. mol^{-1}. cm^{-1})	3.24×10^4	0.96×10^4
Melting point for complex	$283C^0$	$242C^0$
Relative Standard Deviation (n= 6)	1.6%	3%

Effect of reagent concentration: Keeping a constant concentration (10 µg.mL^{-1}) of Co(II) and Ni(II) solutions,the effect of reagent concentration (1.0 x 10^{-3} M) on absorbance of the complexes was studied by varying the amount of the volume of reagent (0.5-4.0) mL. The required volumes of 4-(p-phenyl azo sulfonic acid)-1-naphthol) were found to be 1.5 mL and 2.5 mL to complete the reaction of Co (II) and Ni (II) respectively. The result are shown in fig.5.

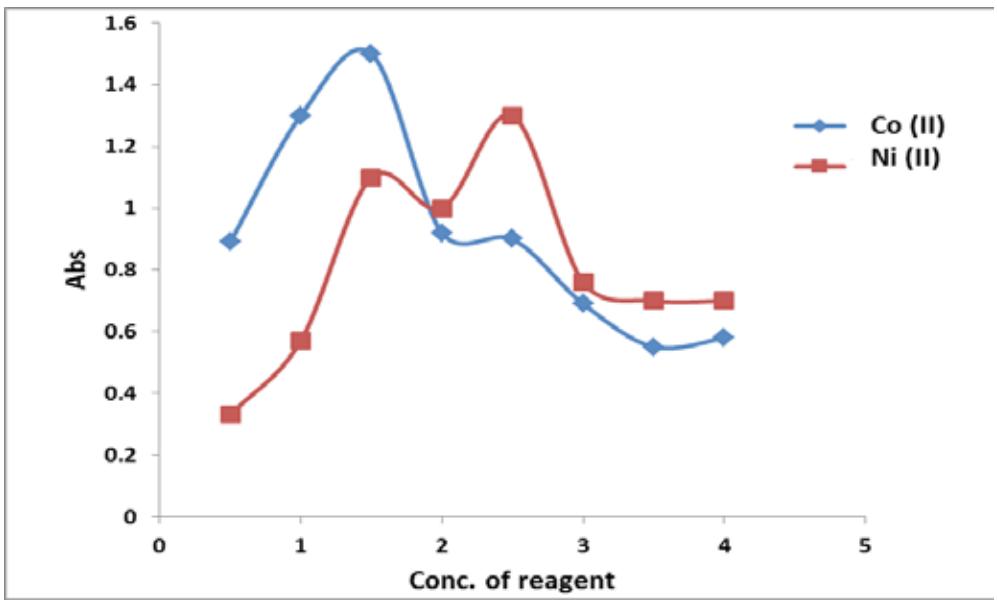

Fig. 5: Effect of reagent concentration

Calibration Graph: The calibration curves obtained show a linear relationship between absorbance and concentration held over range of 0.5-2.5 μg mL^{-1} and 0.1-2 μg mL^{-1} for cobalt and Nickle respectively. The molar absorptivity and Sandell's sensitivity are given in Table.1 .

Composition of the complexes: Job`s method of continuous variations[15] was chosen to study the ratio of metal to reagent, results illustrated in Figures 6. The method indicated that the ratio of metal ion to reagent molecules (M:L) was (1:2) at optimum pH.

Conclusion:

In this study it was shown that 4-(p-phenylazo sulfonic acid)-1-naphthol) could be used as a reagent for the Spectrophotometric determination of Cobalt (II) and Nickle (II). It offers advantages like reliability and reproducibility in addition to its simplicity**.**

The Effectiveness of 7 Counselor Contacts in Health Facility at the First Level to Increase Exclusive Breastfeeding Coverage in Tangerang

Marthia Ikhlasiah[1], Atnesia Ajeng[1], Ika Oktaviani[1]

[1]*Lecturers of University of Muhamadiyah Tangerang, Banten, Indonesia*

Abstract

Breast milk is really beneficial for baby's nerves and brain system development so it can be optimal andit can decrease infection risk. This is not directly proportional with exclusive breastfeeding coverage score in Indonesia, which reached 42% and it is still below of WHO standard one of factors which affects the succeed of giving breast milk was an availability of counselor in Health Service Facility. The objective of the research is to know how deep the beneficial of breastfeeding counseling through 7 counselor contacts based on WHO standard onto mothers and family, especially in increasing breastfeeding coverage score. The research methodology used was quasi experiment. The subject of the research was pregnant women up to the phase of breastfeeding in Health Facility at the First Level in Tangerang. The used sampling technique was purposive sampling. The amount of sample was 30 mothers. The statistical analysis used was t-test paired test. The result shows that all of the samples who got treatment of having 7 counselor contacts reached 100% of breastfeeding until it last to the end. Meanwhile, t test result of counselor contacts with baby's weight was having average differences of newly born baby's weight and in the day 1-3, it was proved with significance score 0,000. The average score of baby's weight who were newly born got 3, 16 kg and in the day of 1-3, got 3, 08kg, means decreased. However, for the t-test paired test, the baby's weight in the day of 1-3, day of 7, day of 14 and day of 40, had average differences with significance score 0,000. The average score of baby's weight in the day of 1-3, in the day of 7, in the day of 14, and in the day of 40 got increased. It can be concluded that the implementation of 7 counselor contacts of breastfeeding based on WHO standard was effective to increase exclusive breastfeeding coverage score and increase baby's weight in Health Facility at the First Level. This research is supposed to be implemented in all of Health Facilities at the First Level, so the score of exclusive breastfeeding coverage increased.

Keywords: *Counselor, Breastfeeding, Breast milk, Exclusive.*

Introduction

The amount of baby's death in Indonesia based on Survey of SDKI shows 23 deaths per live birth. The degree of society's health from the death amount was really far from the SDGS target, that was 12 per 1000 live birth. One of the efforts that can be done to decrease infant mortality rate is giving brestfeeding.[1]

Marthia Ikhlasiah
Lecturers of University of Muhamadiyah Tangerang, Banten, Indonesia
e-mail: marthiaiik@gmail.com

According to the report of Provincial Health Office, coverage distribution of exclusive breastfeeding for baby aged 0-6 months was 54.3%, meanwhile, the percentage in Banten province was still 47.9% below, means it is far from WHO standard (80%). The result of systematic view about the breastfeeding impact in short term and in long term, shows that it can decrease risk of diarrhea, chest infection, asthma, dermatitis atopic, obesity, leukemia, baby sudden death syndrome [2]

Breastfeeding is a precious gift from a mother given to her baby where it refers to process of giving breast milk to baby or to a child from mother's breast. The baby uses reflex of suction to get and to swallow breast

milk. The breastfeeding process has prolactin reflex and letdown reflex[3]. Breast milk has many fruitful things such as through 16 times of breastfeeding given to baby, tends to be rare of being hospitalized, and it has many specific nutrients which enroll in brain development such as dokosaheksaenoat and arachidonic acid for brain and retina development and choline to increase memory[4].

Some factors that annoyed breastfeeding succeed is the lack of mother's knowledge about breast milk advantageous, the lack of physic and mental of mother's preparation, the lack of family support and environment, the lack of health service facility[3]. Therefore, a mother must seek information, so she can do breastfeeding in optimal way. For the mother who wants to succeed of breastfeeding, must dig information from trusted source. Once she gets the information, then she must seek the truth of the information through books or medical staff, such as doctor, midwife, and breast milk counselor[5]

Lactation counselor is (either medic or non-medic background) someone who has followed lactation counselor training based on WHO-40 hours module. Counseling aspect which becomes main activity from a lactation counselor consists of 2 components: listening and accepting opinion or mother's point of view without judging; and help them to decide the best choice based on relevant information and also suggestions that have been given by a lactation Counselor[5]

The lactation Counselor practices all of the skills and the competences that is supposed to have, especially the skill of communication ability as what has been explained above. The lactation counselor and breastfeeding mother and also family work together to discuss and decide the best thing that will be done by the mother that suits with relevant information and also suggestions that have been given by the lactation counselor regards to the condition of that breastfeeding mother.

The research that is conducted by the researcher that entitles " The implementation of breast milk counseling for the pregnant mothers shows the result that they tend to be more patient and more confident to feed breast milk for their baby within the early 3 days of babies born. In the previous research, there is no treatment done through 7 standard counselor contacts of WHO-based and the research time does not answer the succeed of feeding breast milk exclusively within at least 40 days after having the last counselor contact.

Therefore, it needs to do a continuous research through 7 counselor contacts based on WHO standard which is started from 28 weeks of pregnancy age until 40 days of babies' born age. The research is urgent to do since it is very important of giving breastfeeding counseling in order to increase the coverage rate of exclusive breastfeeding

Materials and Method

This experimental quasi research aims at describing the cause effect relation to see the effectiveness of breastfeeding counseling through 7 counselor contacts based on WHO standard. The subject of this research were the coverage rate of exclusive breastfeeding. The object of the research was breastfeeding counseling through 7 counselor contacts. The population in the research was the pregnant mothers. The sample taken in this research used purposive sampling, whose respondents were taken based on specific purpose. This research took 30 sample of mothers.

The quantitative data collection for the breastfeeding counseling consist of: a.) The implementation of 7 counselor contacts for 28 weeks of pregnant mothers, 36 weeks of pregnant mothers, when the baby was newly born, 1-3 days of baby's newly born, parturition within seven days, parturition within fourteen days, parturition within forty days) b.)The observation of exclusive breastfeeding: Made checklist list of the succeed of exclusive breastfeeding mothers. C)the growth of baby's weight: it was done through weigh babys'weight within the contact given in parturition of BBI (contact 3 (IMD)), BB2 (Contact 4 (1-3 days period of hospitalized). BB3 (contact 5 (parturition of day 7) BB4 (contact 6 (parturition of day 14)BB5 (contact 7 (parturition of day 40). The data analysis used was T test require data coming from normal distribution and homogeny. T test used was Paired T-test.

Results

a. The descriptive result of Counsellor contact

Table 1 Counsellor contact with breast milk

7 Counsellor Contact	n	Breast Milk
Meeting I (28 weeks of pregnancy)	30	-
Meeting II (36 weeks of pregnancy)	30	-
Meeting III Newly born baby (IMD)	30	100%
Meeting IV 1-3 days of newly born baby	30	100%
Meeting V Parturition within 7 days	30	100%
Meeting VI Parturition within 14 days	30	100%
Meeting VII Parturition within 40days	30	100%

b. The descriptive result of Counselor contact with baby's weight

Table 2 Contact with baby's weight

	n	Minimum	Maximum	Mean
BB1 {Third contact (IMD)}	30	2.80	3.60	3.1567
BB2 {Fourth contact (1-3 days of being hospitalized	30	2.70	3.50	3.0767
BB3 {Fifth contact (Parturition within 7 days)}	30	2.80	3.60	3.1800
BB4 {Sixth contact (Parturition within 14 days)}	30	3.00	3.80	3.3700
BB5 {Seventh contact (Parturition within 40 days)}	30	3.20	4.00	3.5633
Valid N (list wise)	30			

1. The average score of baby's weight in the third contact was 3.16 kg and in the fourth contact, the baby's weight was 3.08. It means decreased
2. The average score of baby's weight in the fourth contact was 3.08 kg and in the seventh contact, the baby's weight was 3.18. It means increased
3. The average score of baby's weight in the seventh contact was 3.18 kg and in the fourteenth contact, the baby's weight was 3.37. It means increased
4. The average score of baby's weight in the fourteenth contact was 3.37 kg and in the fourth contact, the baby's weight was 3.56. It means increased

c. The Normality test of Counselor contact with baby's weight

Table 3 Normality Test

Statistic			**Df**	**Sig.**
BB1 {The third contact (IMD)}			30	.200*
BB2 {The fourth contact (1-3 days of baby's born being hospitalized)			30	.194
Levene Statistic		**Sig.**		
BB1-BB2	Based on Mean	.845		
	Based on Median	.850		
	Based on Median and with adjusted df	.850		
	Based on trimmed mean	.842		
BB2-BB3	Based on Mean	.798		
	Based on Median	.765		
	Based on Median and with adjusted df	.765		
	Based on trimmed mean	.800		
BB3-BB4	Based on Mean	.316		
	Based on Median	.348		
	Based on Median and with adjusted df	.348		
	Based on trimmed mean	.316		
BB4-BB5	Based on Mean	.937		
	Based on Median	.844		
	Based on Median and with adjusted df	.844		
	Based on trimmed mean	.927		
BB3 {The fifth contact (Parturition within seven days)}			30	.170
BB4 {The sixth contact (Parturition within 14 days)}			30	.151
BB5 {The seventh contact 7 (Parturition within 40 days)}			30	.051

In the normality test, the data will be normally distributed if the significance score was higher than 0.05. The normality test result shows that significance score was higher than 0.05. It means it can be assumed that it fulfils to do parametric test.

d. The homogeneity test of counselor contact with baby's weight

Homogeneity Test: The homogeneity test, if the significance score from levene statisticis higher than 0.05. Homogeneity test is to do to know whether the data coming from the same population or not. The above result shows the all of data groups have the significance score higher than 0.05. It can be said that it is homogeny. Therefore, the assumption of homogeneity was fulfilled, then parametric test can be tested. The used parametric test was paired t test.

e. Paired TTest

Table 4. Paired Samples Test

	T	Df	Sig. (2-tailed)
Pair 1 BB1 {The third contact (IMD)} – BB2 {The fourth contact (1-3 days of babies born being hospitalized)}	5.442	29	.000
Pair 2 BB2 {The fourth contact (1-3 days of babies born being hospitalized)} – BB3 {The fifth contact (Parturition within seven days)}	-13.676	29	.000
Pair 3 BB3 The fifth contact (Parturition within seven days)} – BB4{The sixth contact (Parturition within 14 days)}	-7.577	29	.000
Pair 4 BB4 {The sixth contact (Parturition within 14 days)} – BB5{The seventh contact (Parturition within 40 days)}	-29.000	29	.000

1. There is significance average differences of baby's weight in scale of day if the significance score was lower than 0.05
2. There is significance average differences of baby's weight in day 3 and day 4 which is proved with the significance score 0.000 (sig<0.005)
3. There is significance average differences of baby's weight in day 4 and 7 which is proved with the significance score 0.000 (sig<0.005)
4. There is significance average differences of baby's weight in day 7 and 14 which is proved with the significance score 0.000 (sig<0.005)
5. There is significance average differences of baby's weight in day 14 and day 40 which is proved with the significance score 0.000 (sig<0.005)

Discussion

From the data collection shows that the 7 counselor contacts have been executed with 100% coverage and the baby's weight was 100% normal > 2500gram. The baby's weight average after being born, mean was 3.100 gram, it is upper from the normal line of the lowest data 2.800 gram and the higher data when baby just being born was 3.600 gr, then the baby's weight increased from each step of counselor activity. The breast milk was given simultaneously and continuously. However, there was a decrease of baby's' weight average score in the third contact, that was 3.16 kg and in the fourth contact 3.08. This decrease was about 2.5%. This happened was not merely caused the lack nutrition of breast milk, but it happened because of the theoretically stated it was normal weight decrease. For the newly born baby, the normal decrease of weight was estimated 5-7%, then it must be a weight gain at least reach 20 gram per day. The content of breast milk has protective factor and proper nutrientthat guarantee the nutrition status of baby and also illness and death of babies were decreased. Some epidemiology research result that breast milk can protect baby from infection illness. The early introduction about foods that are low in nutrients and energy served in unhygienic can decrease children's nutrition and can have low body endurance[6].

The research about nutrition counseling and intensive lactation and husband's support about exclusive

breastfeeding until the baby's age reach 1 month conducted by Ramlan[7] Shows that there is significant difference between control group and experiment group with p= 0.000

The same research was done by Febriani[8] explained that all of respondents, 66 persons and from 35 respondents who did7 breast milk counselor contacts in UPTD Puskesmas Lingkar Barat Bengkulu were 27 persons succeed giving exclusive breastfeeding (77, 1%),the succeed of breastfeeding with p value chi square test p=0,000 (<0.05). In American Journal of Heath Promotion 2013 "The Effectiveness of multilevel promotion of exclusive breastfeeding in rural Indonesia" explained that structured health promotion can increase breastfeeding. BMC journal entitles "Developing a workplace lactation promotion model in Indonesia using Delphi Technique" explained that a wisdom of a company which provides breastfeeding counselor can increase human resource. By the existence of counselor, an employee can work properly if need of the baby's breast milk is fulfilled.

The research conducted by Mulyani[9] explained that by giving counseling of breastfeeding, it can increase the attitude of post-partum mother's breastfeeding effectively after being given the counseling in the period of prenatal, intranatal, and postnatal. The research about breastfeeding counseling toward baby's weight was also conducted by Ni Putu[10]. The result shows thatthe counseling can increase mother's knowledge about breastfeeding, so it affects mother's awareness to give exclusive breast milk and it also affects baby's weight gain. Therefore, from the result of the research, it can be said that 7 counselor contacts have run effectively, so Health facility in the First Level and Health Staff actually hold strategic role to increase coverage of exclusive breastfeeding until the baby's age reach 6 months[11-14].

Conclusion

It can be concluded that the implementation of seven counselor contacts based on WHO standard in Health facilty at the First Level, affect babys' weight gain. It also increase score of coverage of exclusive breastfeeding by seeing baby's weight gain. The implementation of this research hopefuly for all of Health Facilities at the First Level use 7 counselor contatcs, so score of coverage of exclusive breastfeeding increased based on WHO standard.

Survey of Registered Nurses Working in the Metropolitan Hospitals on Bullying Experiences at Workplace in South Korea

Kwang Ok Lee

Associate Professor, Department of Nursing, Sangmyung University, South Korea

Abstract

This study aimed to identify the bullying experiences and coping patterns experienced by clinical nurses. A total of 215 nurses who had worked at 10 hospitals in Seoul from 3 September 2019 to 20 October participated, but two of them had missing data. Ultimately, 213 subjects were included. The collected data were analyzed using the SPSS/WIN20.O program which were analyzed using the mean and standard deviation. Subjects who experienced bullying accounted for 110 out of 213 (51.6%) in which 66.3% were experienced nurses and 21.8% were new nurses. To talk to a colleague was 57.3%, to work with a feeling of hurt but remain calm was 56.4%, to forget by thinking about something else or doing something was 50%. The study on the coping response after bullying has not been revealed in previous Korean reports, and it is expected to be a useful information for preventing workplace bullying in the future and establishing an immediate and active coping system.

Keywords: *Registered Nurses, Metropolitan hospital, bullying experience.*

Introduction

Persistent bullying in the workplace can have a serious impact on physical, psychological, and social health conditions. Anxiety, depression and stress, insomnia, weight loss, low self-esteem, and psychological atrophy are the most severe reactions. Traumatic stress disorder may also occur[1].

Persistent bullying in the workplace can have a serious impact on physical, psychological, and social health conditions.

Anxiety, depression and stress, insomnia, weight loss, low self-esteem, and psychological atrophy are the most severe reactions. Traumatic stress disorder may also occur[1].

SangMyung University, South Korea
e-mail: kolee@smu.ac.kr

Workplace bullying can also lead to burnout, leading to decision-making[2]. Workplace bullying not only causes physical and mental damage to individuals; it also leads to business mistakes, reduced productivity, and turnover in the organization.

The bullying of nurses in Korea has been studied, but the study on how to cope with the situation of bullying has been seldom conducted. In addition, bullying among new nurses has been largely reported, but no bullying experiences in career nurses have been studied. Therefore, this study examined the bullying experiences of career nurses as well as the new nurses. It also confirmed the violence status as a basic information for generalizing the occupational violence reporting system and prepared guidelines for creating a safe working environment. Hence, these steps are immensely necessary.

Purpose of Research: This study aimed to investigate the bullying status, post-bullying reactions, and coping patterns experienced by clinical nurses.

First, we investigated the bullying experiences experienced by nurses. Second, we examined the

differences in bullying experienced by nurses. Third, we investigated the coping behavior according to the bullying situation experienced by the nurses.

Method

Design and Sample: This study used the descriptive research method to determine the status of bullying experienced by nurses and the reaction and coping patterns they demonstrated after being bullied.

Data Collection: This study was approved by the Institutional Review Board of Institutional Review Board (IRB C-2019-003). The research coordinator contacted the staff in each hospital to explain the purpose and procedure of the study and then sent a website address and a questionnaire. The nurses could freely choose on whether to answer in a questionnaire or through the website, and then the data were collected. A total of 215 nurses who had worked at 10 hospitals in Seoul from 3 September 2019 to 20 October participated, but two of them had missing data. Ultimately, 213 subjects were included

Instrument:

Negative Acts Questionnaire-Revised (NAQ-R): The NA1-R tool was developed by Einarsen and Raknes[3], but it was translated by Nam et al. The self-report questionnaire consists of 22 questions. It is divided into three sub-domains, namely, personal harassment, physical threat, and work harassment. A high score of 22 to 110 indicates that more negative behavior was experienced.

Coping with Bullying: This instrument, which consists of 13 questions, was created by modifying and supplementing the coping measures for violence presented by Kim and Kwon [18]. The questions can be answered with either yes or no.

Data Analysis: The collected data were analyzed using the SPSS/WIN20.O program. The subjects' general characteristics, job-related characteristics, post-violent coping behavior, and failure to report were analyzed using the mean and standard deviation.

Results

General Characteristics of Subjects: The 213 subjects were composed of 5.2% male and 94.8% female. The age of patients ranged between 25 and 53 years, with a mean of 29.7±7.22 years. The average work experience of nurses was 5.58±7.26 years in which 26.3%, 64.8%, and 7.5% were new nurses (worked for less than a year), experienced nurses, and other nurses, respectively. The medical wards were followed by internal medical wards (25.4%), surgical wards (17.8%), intensive care unit (17.4%), and outpatient (13.6%) (Table 1).

Bullying Experience Related to Characteristics: Subjects who experienced bullying accounted for 110 out of 213 (51.6%) in which 66.3% were experienced nurses and 21.8% were new nurses. Furthermore, 50% of the respondents took immediate action after the bullying experience, and 51.8% thought of leaving the job after the bullying experience (Table 2).

Table 2. Bullying experience related to characteristics (N=110)

Characteristics	Bullying	n(%)	X^2 (*p*)
Current position	New graduate RN Registered Nurse Unit manager Clinical nurse educator	24(21.8) 73(66.3) 11(0.1) 2(1.8)	3.96 (.265)
Action after report bullying	Immediately action No action	55(50.0) 55(50.0)	
Turnover intention related bullying	Yes No	57(51.8%) 53(48.2%)	

Ways of Coping: To talk to a colleague was 57.3%, to work with a feeling of hurt but remain calm was 56.4%, to forget by thinking about something else or doing something was 50%, to talk to friends or family was 46.4%, to avoid eye contact was 41.8%, and to remain inactive (attractive) was 40.9% (Table 3).

Table 3. Ways of Coping (N=110)

Variables	n(%)
Report to Administrator	16(14.5)
Talking to friends or family	51(46.4)
Talk to a colleague	63(57.3)
Creates an incident log	8(7.3)
Rport to the police	3(2.7)
Inactive (attractive)	45(40.9)
To forget while thinking about something else or doing something	55(50)
Consultant found	6(5.5)
Indirect expression of displeasure	23(20.9)
Ask someone close to you for help	21(19.1)
Avoid eye contact	46(41.8)
Trying to understand the other person	34(30.9)
To work with a feeling of hurt, but calm down	62(56.4)
Drinking alcohol	34(30.9)
I don't know what to do. I don't know what to do.	30(27.3)

Discussion

In addition, violence was reported in 75% of Australian nurses[5] and 33% of Canadian nurses[6]. Nurses have been experiencing bullying at various sites, such as emergency rooms[7], psychiatric wards[8], and communities[9].

This study found that coping with bullying involved talking to colleagues most frequently. This result is similar to that of Kang Hee Sun[9]. Therefore, the training should include guidance on how to cope with co-worker bullying.

In previous studies[10], older nurses experienced more workplace harassment, but in the current study, 26.3% of new nurses and 64.8% of experienced nurses experienced more workplace harassment. According to the nurse's career, the shorter the experience of working as a nurse, the more frequent the bully experiences[11]. Meanwhile, the findings were similar to studies reported by nurses in medical wards experiencing more workplace harassment[10,11].

In recent years, an incident has been reported that nurses' workplace bullying has resulted in death; thus, the Ministry of Health and Welfare urgently needs to discuss on the strong implementation of education and preventive measures against bullying. In addition, in the event of bullying, a systematic incident reporting system should be in place and encouraged to respond proactively.

In Korea, various activities, such as 100-day ceremonies and one-year ceremonies to adapt to new nurses, are implemented; however, support programs for career nurses are not well run. Therefore, running support programs for them is necessary.

In addition, considering that nurses who experience workplace bullying may later become perpetrators[12], preventative interventions and policies according to the ladder system of new nurses and experienced nurses are necessary to be established. The main influencing factors of workplace bullying are organizational factors instead of individual ones[11]. Moreover, the development and training of such preventive programs, the encouragement of reporting systems after bullying, instruction and guideline education, and immediate and active response programs should be actively and continuously operated.

Conclusion

Not only new nurses but also experienced nurses and unit managers were exposed to workplace bullying. Recently, nurses who died from workplace bullying encountered industrial accidents and were aware of the guidelines for preventing bullying. However, they did not have specific training for harassment prevention, reporting system, and guidelines. Preventive education and immediate action in case of bullying should be strengthened starting from the nursing college days. Furthermore, the safety guidelines should be reinforced through education and include the contents of annual nurse remuneration education to support legal and institutional safe working conditions.

The study on the coping response after bullying has not been revealed in previous Korean reports, and it is expected to be a useful information for preventing workplace bullying in the future and establishing an immediate and active coping system.

Right to Life of a Child in India: An Overview

Arunima Mishra[1], Smita Satapathy[2]

[1]Assistant Professor, Faculty of Legal Studies, Siksha 'O' Anusandhan, Bhubaneswar, Odisha, India,
[2]Ph.D. Research Scholar, Faculty of Legal Studies, Siksha 'O' Anusandhan, Bhubaneswar, Odisha, India

Abstract

It would not be an exaggeration of words if it is said that children are the future of a nation. They are the representatives of the older generation in the upcoming world. They are filled with innocence and their innocence should be nurtured so as to make it persistent and to make the society free of corruption. Their level of curiosity is very high and if it is preserved and explored then every child may become a research-oriented scientist, doctor, engineer or likewise. The most prominent international instrument through which the child right has got recognition is the Convention on Rights of Child, 1989. India being a signatory to it is complying with the standards laid down in it.

Keywords: *Child right; right to life, identity and education; convention; Pre-natal injuries.*

Introduction-

"There is no trust more sacred than the one the world holds with children. There is no duty more important than ensuring that their rights are respected, that their welfare is protected, that their lives are free from fear and want and that they can grow up in peace." –Kofi Annan

Children are the backbone of a country. If they are not brought up properly, the nation will have to pay for it. It is quite evident from the world history that as *Adolf Hitler*(1889-1945), in his childhood had grown hatred feelings against the Jews because he could not enter drawing school due to them. Those days the top places were only occupied by the Jews. With his growing age, the hatred feeling has also grown up. Millions of children have no access to education, proper sanitation, immunization, food and health care; instead they have to work for long hours under hazardous conditions and are forced to serve as soldiers in armed conflicts across the globe. And it is very devastating to admit that in many cases, they are abused by the very individuals responsible for their care.[1] Abusing the rights of the children is a much aggravated form of activity in comparison to that against adult people. Spoiling the childhood will lead towards generating anti-social elements and consequently it will spoil the society at large.

Objective:

The purpose of research on this topic is-

1. To know the correlation between the right to life under Article 21 of the Indian Constitution and provisions under the Convention on Rights of Child.
2. To understand children's right to life in India.
3. To know how the judiciary is tackling these types of cases relating to various child rights.

Various Rights of Children: There is no doubt that children are entitled to all the facets of human rights, but as they are unable to take care of themselves, are representing a very vulnerable and sensitive group they are entitled to some additional rights. According to United Nations Convention on the Rights of the Children (adopted by the United Nations General Assembly on 20th November, 1989 and came into force on 2nd September, 1990) which has been ratified by India in 1992 (Till now 196 member countries have ratified to it except USA) – all children are born with fundamental rights.If right to life of a child is considered then it is having three important facets, namely-

- Right to existence which definitely includes right to born alive,
- Right to identity which in turn ensures the liability of the state to take care of the child and its rights, and
- Right to education which enables the child to live a life like a social being with due dignity.

Juvenile Delinquency as a By-Product of Violation of Child Rights: If anyone has a look to the factors contributing to juvenile offences- they are poor school attendance, poor educational standard, violence at homes, violence in the social circle, bad peer group and their pressure, socioeconomic causes, lack of moral guidance, lack of basic amenities, adolescent instabilities and impulses, early sexual experiences, mental conflicts, child marriages and media and artificial intelligence etc. among the aforesaid factors except few psychological factors every other factor has a direct connectivity with the serious violation of child right. However it can also be said that most of the psychological factors are the outcome of violation of child rights at a very early childhood.

Important Provisions of Convention on Rights of Child: The history of children's rights dates from the 19th century. In ancient times and up to the middle Ages, though it is very devastating to admit still in some parts of the world parents even had the power of life or death over their children. For the first time in Europe, laws were passed governing child labour.[2] In 1919, the League of Nations created a committee for the protection of children. Five years later, it adopted the Geneva Declaration, first international treaty on children's rights, then after the Second World War there was rapid growth in the concern regarding child rights. In 1948 the Universal Declaration on Human Rights stipulated that the motherhood and childhood are entitled to special care and assistance. Then finally on 20th November 1989 the Convention on the Rights of the Child (CRC) was unanimously adopted by the United Nations General Assembly. In 2000 the Convention got more strength due to adoption of the two optional Protocols on the sale of children, child prostitution and child pornography, and child involvement in armed conflicts. In 2011 the third optional protocol was adopted introducing a mechanism by which children may submit complaints to the Committee on the Rights of the Child. 2014 is the year of 25th anniversary of the Convention and now it has been ratified by 193 member states of the United Nations. Only the United States and Somalia, who have both signed the treaty, have not ratified it.

Article 1 of the 1989 Convention provides the definition of a child on the basis of age. According to the provision children below the age of 18 years are entitled to the rights enumerated under the Convention, but autonomy is also given to the member countries to formulate a definite and uniform age. But still India is having no uniform law regarding this. Article 2 provides for non-discriminatory treatment to the children. Protection of the child rights are provided under Article 4. Among other important provisions are parental guidance under Article 5, respect for the views of the child (Article 12), freedom of speech and expression (Article 13) and freedom of thought, conscience and religion (Article 14) and right to education including goals of education under Article 28 and Article 29 etc. As provided under Article 42 the member countries should take the appropriate steps to make the adults and children know about the rights of the children as provided. Articles 43 to 54 deal with the implementation mechanism.

Implementation in India: To start with every child has a right to be born alive and then to the basic amenities of life those are- food, clothes and shelter and of course including right to health care including immunization. The right to born alive abandons all forms of foeticide. A child needs to be taken care of in a proper manner while inside the mother's womb. The judiciary of some countries like California (*Scott vs. Mc Pheeters*, 33 Cal App), Lousiana (*Cooper vs.Blanck*, 39 so, 2d 352), Canada (*Montereal Tramways vs.Leveille* 4 (1933)) and Columbia (*Bonbrest vs. Kotz* 65F Supp 138 (1946)) are allowing actionable claims in case of pre-natal injuries though in ***Walker* vs.*Great Northern Railway, Ireland***[(Q.B. Div) 69 (1891)] the same was denied against the defendant's Railway Company when a child was born deformed because of the railway accident of his mother. But Indian judiciary is far behind regarding these kinds of claims. India has no statute dealing with prenatal injuries unlike United Kingdom. Under the Congenital Disabilities (Civil Liabilities) Act, 1976 of England—

(a) The action is allowed if the child is born alive, but deformed;

(b) Damages for the loss of expectation of life of a victim child can be claimed if the child lives at least 48 hours after birth;

(c) Civil liability towards the child can be however restricted or excluded by a contract made with the parents;

(d) Contributory negligence of the parents can be pleaded as a defence;

(e) It is permitted to bring an action for injury to the child even against the mother if the cause of action arises due to the negligent driving of the mother.

Indian Courts when faced with the question of liability of the mother to her child in the womb for injuries caused by negligence have the following options-

(1) They hold the mother liable for negligence generally in all cases; or

(2) There is denial to impose any liability for negligence in any case; or

(3) Holding the mother liable for negligence only in motor accident cases

In the case of ***Union Carbide Corporation vs. Union of India*** (AIR 1992 SC 248) it was held by the Apex Court that if the congenital defect of a child is traceable to be caused by noxious gas leaked during the Bhopal Gas Leak Disaster then compensation would be allowed. This pronouncement by Apex court can only be served as a directive and is not exactly backed by any statute or it can be utilized authoritatively. However, legal liability can never be imposed upon a mother to take care of the foetus inutero. Judicial or legal definition of"reasonable standard of care"which a mother owes to her foetus would be very difficult to articulate as myriad of financial capacities, educational qualifications, access to health services and ethnic backgrounds of the women can be seen in the Indian society under which imposition of such liability is almost impossible.

However Sec. 140(2) of the Motor Vehicle Act, 1988 (Act No. 59 of 1988) provides for a compensation of Rs 25,000 to an accident victim who sustains permanent disability because of the accident. This liability is covered under the insurance policy against third party risk[3] subject to condition that a foetus must be covered under the definition of 3rd party. But actually who can be included within the term 3rd party is not comprehensively provided under the said Act. However the right to file a civil claim of tort is still preserved[4]. Indian Transfer of Property Act, 1882 recognises an unborn person in whose favour property can be transferred[5].

Regarding nutrition and health Indian Government and various state governments have taken various policy measures. Many schemes like Mid-day meal Scheme, Sarva Sikhya Abhiyana Scheme, Integrated Programme for Street Children, Balika Samriddhi Yojana and so on. Right of the children to development includes right to education as well as right to leisure, recreation and care. However how to ensure the entitlement, extent and enjoyment of these rights is a big question. Article 8 of the CRC 1989 provides for Preservation of identity of a child. It enshrined that children have the right to an identity. Governments should respect children's right to a name, a nationality and family ties. Indian government has passed the Aadhaar (Targeted Delivery of Financial and other Subsidies, Benefits and Services) Act (No. 18 of 2016) was passed in 2016. The compliance of the Act by Aadhar registration of children is still in question due to various contradictory judgements of the Supreme Court. The only option left is birth registration in concerned municipalities under the Registration of Births and Deaths, Act 1969 (Act No. 18 of 1969). But till now each and every birth is not registered. Particularly the children taking birth in slums, brothels and of parents in begging or any kind of nomadic profession are not having their children's births registered.[6] As this is purely a duty of parents, uneducated and illiterate parents need to be trained continuously regarding registration process as well as the significance of it.

If the right to education and goal of education provided under A. 28 and A. 29 of the 1989 Convention are considered then India has taken two important statutory steps as follows-

- Insertion of Art 21A and Art 51A(k) to the Constitution in 86th Amendment to the Indian Constitution in 2002; and
- Passing of Right to Free and Compulsory Education, Act 2009 (Act No. 35 of 2009)

Article 21A gives the right to education the status of a fundamental right and art 51A(k) castes a duty upon the parents of the children within 6 to 14 year of age to send them to school. But the beneficiaries of art 21A are minors and they are unable to enforce the same and as it is known to everyone that it is very difficult to ensure the compliance with a fundamental duty. The Right to Education Act provides for the:

- Completion of elementary education(i.e. up to standard VIII) within 6 to 14 year of age;

- Standard student-teacher ratio, infrastructural facility, teachers' working hour including schools' working hours;
- Appointment of appropriately qualified and well trained teachers; and
- Prohibition of punishment or harassment in any form, strict admission procedure by screening, imposing high fees by private schools, employment of teachers for non-academic purposes like elections, relief, census etc, engagement of full-time teachers as private tutors, etc. Many more provisions are there to ensure the nourishment of the potentials of every child.

Right to Education and the Reality: Now three kinds of course curricula are running in India specifically in the elementary level. Those are ICSE (Indian Certificate of Secondary Education), CBSE (Central Board of Secondary Education) and education provided by local or state Board. In the ICSE course pattern the papers are many and the books are very huge in volume and very much information oriented. Automatically the examination needs to be memory-based and it evaluates only the memorisation aspect of a child.[7] No thought provoking questions are ever asked. The students need to learn everything by heart. So students are so extraordinarily burdened that no room is left for their creativity and decide what is moral and what is immoral and perhaps that's why students are competing like anything in getting a seat in a good college and a good job, but fraction of a second is taken for a government servant to be corrupted.[8]

The ground reality in Indian context is that now a day people belonging to the middle and lower middle class have become more conscious regarding the education of their children, but they have become so ambitious that their children have to pay for it.[9] The significance of education as understood by their children is that good education is meant to secure good marks, then consequently to get a good job and finally to get good salary.[10] In these cases more often it is seen that the children are unable to accept their failure and develop suicidal tendencies which shows a growing escapist attitude.[11]

Findings: In order to ensure that every child will enjoy the right to education parents also need to be conscious. The duties of the government are to-

- Attach the birth registration with the census by some statutory or policy measures so that every birth can be registered and the child population can be assessed properly.
- There should be a uniform law regarding the age of the beneficiaries of child rights.
- To bring amendment in the Right to Education Act, 2009 to lessen the burden of the courses so that the child can enjoy the studies.
- The examination system is so modified by the policy measures that the proper evaluation of the child could be possible by,
    - Finding the problem or the huddle for the child; and
    - Finding the real potential of the child which can further be explored.
- Parents should not be imposing their wishes upon their children realising the fact that their children are separate individuals.

Conclusion

The children are not the responsibility of the state only. The society, the parents and every relatives, kiths and kin, the quasi parents or teachers whoever are custodian of a child for howsoever small period it may be should think that they are a part and parcel of the process of child up-bringing. So a child is everyone's responsibility.

Influences of Mothers' Parenting Attitude, Parenting Efficacy, and Stress Levels on Children's Social Skills

Kwang Ok Lee[1], Hyun Ju Chae[2]

[1]*Associate Professor, Department of Nursing, Sangmyung University, South Korea,*
[2]*Associate Professor, Department of Nursing, Jungbu University, South Korea*

Abstract

This study aimed to identify the influences of mohers' parenting attitude, parenting efficacy, and stress levels on children's social skills. A total of 117 mothers rearing 4–7-year-old children were included in this study. Data were collected using as elf-administered questionnaire from November 13 to 26, 2011. Collected data were analyzed using the IBM SPSS 20.0 program with descriptive statistics, t-test, one-way analysis of variance (scheffetestforpost-hoc), Pearson's correlation, and multiple regressions. Mothers' parenting attitude (permission) and efficacy were positively correlated, whereas mothers' stress level was negatively correlated with children's social skills. Children's social skills were influenced by mothers' parenting and marital stress levels and children's gender and birth order. In addition, mothers' occupational so influences children's social skills. These results indicated that differences in gender and birth order should be considered in providing interventions for mothers' stress management.

Keywords: *Parenting efficacy, parenting attitude, stress, children, social skill.*

Introduction

Individuals should interact with others and make social relationships when growing up[1]. Intimate relationships are the most important factors for a happy life, which require social skills to form and maintain[1]. The importance of social skills for successful lives has increased nowadays as compared to the past, which is expected to be greater as human relations become more complex and diverse[1].

Social skills can be defined as socially acceptable learned behaviors for the successful completion of social task such as peer-group entry, having a conversation, making friends, and playing games with peers[2]. These skills are intrinsic to children's psychosocial well-being[3] and related to their positive behavioral, social, and academic outcomes[4]. Young children's social skills are an important precursor in their development for school readiness and peer acceptance and considered as academic enablers because they facilitated academic achievement[4].

Children grow up as socialized adults through learning and practicing social skills by considering, conferring, and cooperating with each other in various social relations[1]. Children with good social skills are more likely to participate in cooperative play, which enhances their social skills[5] and makes them adapt well socially, whereas those lacking social skills are more likely to play alone, which promotes insufficient opportunity to learn social skills[5]. These children are more likely to experience difficulty in resolving conflicts arising from various social relationships and show socially maladaptive behavioral problems[5]. These negative experiences can affect their overall development and last until adulthood[1]. Therefore, children's social skills should be increased by identifying the influencing factors.

Children's social skills are influenced by environmental and individual factors[6]. Environmental

e-mail: hjchae@jbm.ac.kr

factors include parents or teachers, such as parenting attitude and behavior[7], mother–child attachment, stress coping mechanism, and teacher–child interaction[2]. Individual factors include temperament, sex, and emotional intelligence[8]. Among these factors, parents are considered too closely influence the development of children's social skills, especially mothers' parenting[6]. Children begin to learn social skills through relationships with their mothers, which is the primary basis of children's social relationships[9].

Therefore, the relationship between factors related to mothers' parenting and children's socials kills should be identified. Previous studies reported that mothers' parenting attitude and stress levels were related to children's social skills[6]. However, children's social skills were evaluated by teachers in most studies and by parents in some studies[1]. Teachers are more likely to observe and evaluate children objectively; however, their observations are limited within educational institutions. Mothers may lack objectivity as compared to teachers; however, they have been able to provide diverse and accurate information about their children because of their intensive observation in various situations for a long time[1]. Therefore, mothers' evaluation should also be considered in order to understand children's socials kills. In addition, mothers' stress level can also affect children's social skills because of its association with parenting behaviors. Mothers' parenting efficacy can also affect children's social skills for the same reason; however, studies on these issues are limited.

Therefore, this study aimed to investigate children's social skills evaluated by their mothers and to identify the effects of mothers' parenting attitude, parenting efficacy, and stress levels.

Materials And Method

Design and Participants: This research survey was conducted to identify influences of mothers' parenting attitude, parenting efficacy, and stress levels on children's socialskills.

Study participants consisted of 117 mothers rearing 4–7-year-old children recruited at daycare centers in Seoul, Jeonbuk, and Chungnam. Data were collected using a self-administered questionnaire from November 13 to 26, 2011.

Research Tools: Mothers' parenting attitude was measured using a modified Kim's parenting behavior scale [10]. This scale consisted of 3 categories (permission, acceptance, and restriction), and each category consisted of 6 items. Eachitem was rated on a 4-point Likert scale (1– 4), with higher score indicating higher permissive, acceptance, and restrictive behaviors. The internal consistency reliability was Cronbach's a =.76~90 in Kim's study and .82–.90 in this study.

Mothers' parenting efficacy was measured using a modified parenting efficacy scale developed by Choi and Chung[11]. This scale consisted of 20 items, and each item was rated on a 4- point Likert scale (1–4), with higher score indicating higher parenting efficacy. The internal consistency reliability was Cronbach's a =.92 in Choi and Chung's study and.91 in thisstudy.

Mothers's tress level was measured using a scale developed by researchers. This scale consisted of 3 categories (parenting, economic, and marital stress levels), and each category consisted of 4 items. Each item was rated on a 4-point Likertscale(1– 4), with higher score indicating higher stress levels. The validity of this scale was verified by three nursing professors, and the internal consistency reliability was Cronbach's a =.85—.91

Children's social skills was measured using a modified Kim's scale[12], translated from the Social Skill Rating developed by Gresham & Elliott. This scale consisted of 3 categories (assertiveness, self-control, and cooperation), and assertiveness consisted of 10 items and the others consisted of 8 items. Each item was rated on a 4-point Likertscale (1–4), with higher score indicating higher social skills. The internal consistency reliability was Cronbach's a =.82— 94 in Kim's study and .90–92 in this study.

Data Analysis: The IBM SPSS 21.0 program was used for data analyses. Descriptive statistics was used for the participants' general characteristics and study variables. T-test or one-way analysis of variance was used to determine differences in children's social skills according to general characteristics. Pearson's correlation was used to identify the relationship between research variables, and multiple regression was used to identify the influencing factors of children's social skills.

Results

General Characteristics: The general characteristics of study subjects are shown in Table 1. Majority of mothers are in their 30s (70.1%) and

graduated from auniversity (48.7%). Then umber of mothers without job was higher than those with job, and majority had a monthly income of approximately 2–3 million won (44.4%).

Majority of children aged 6 years (35.9%); then umber off em ale children (50.4%)was higher than that of male children; and most of them were firstborn (52.1%).

Table 1: General characteristics

Characteristics	Categories	n (%)

Study Variables: Table 2 shows the study variables of this study. As regards the mothers' parenting attitude, acceptance attitude has the highest (19.49 out of 24), whereas restrictive attitude has the lowest (16.63 out of 24) points. Mothers' parenting efficacy was 65.51 out of 80 points. Mothers' stress level was highest in parenting (9.55 out of 16 points) and lowest in economic stress levels (7.91 out of 16 points). Children's social skill was highest in assertiveness (27.64 out of 40 points, i.e., 69.1 out of 100 points) and lowest in cooperation (21.02 out of 32 points, i.e., 65.69 out of 100 points).

Table 2: Study variables

Parenting Attitude	Possible Range	
	Range	M±SD
Restriction	6~24	7~2416.63±3.36
Permission	6~24	8~2417.09±2.65
Acceptance	6~24	10-2419.49±2.88
Parenting efficacy	20~80	35-7865.5±7.35
Stress	12~48	15-3626.50±5.35
Parenting stress	4~16	4-15 9.55±2.24
Economic stress	4~16	4-14 7.91±2.59
Marital stress	4~16	4-16 9.03±2.51
Social skill	26-104	33-9670.18±13.44
Assertiveness	10-40	11-3827.6±5.94
Self-control	8~32	8-31 21.50±4.36
Cooperation	8~32	11-2921.02±4.07

Correlation of parenting attitude, marital stress levels (r=-.209, p=.024) were negatively correlated with children's assertiveness.

Mothers' parenting attitude (permission) (r=.229, p=.013) and parenting efficacy (r=.251, p=.006) were positively correlated with children's self-control. Mothers' parenting(r=-.350, p<.001) and marital stress levels (r=-.289, p=.002) were negatively correlated with children's self-control.

Mothers' parenting attitude (permission) (r=.269, p=.003) and parenting efficacy (r=.311, p=.001) were positively correlated, whereas mothers' parenting (r=-.395, p<.001) and economic stress levels (r=-.239, p=.009) were negatively correlated with children's cooperation.

Table 3. Correlation

Assertiveness		Self-control	Cooperation

Economic stress	-.238(.010)	-.176(.057	-.239(.009)
Marital stress	-.209(.024)	-.289(.002)	-.164(.077)

Factors influencing children's social skill

Factors influencing children's social skill

Parenting efficacy, and stress levels of mothers on their children's social skills

Correlation of parenting attitude, parenting efficacy, and stress of mothers on their children's social skill is shown in Table 3. Mothers' parenting efficacy was positively correlated with children's assertiveness (r=.198, p=.033). Mothers' parenting (r=-.347, p<.001), economic (r=-.238, p=.010), and are shown in Table 4. Children's assertiveness was influenced by children's gender and mothers' parenting stress levels, which accounted for 23.9%; self-control was influenced by children's gender and birth order and mothers' parenting and marital stress levels, which accounted for 29.3%; and cooperation was influenced by children's gender and birth order and mothers' presence of occupation and parenting stress levels, which accounted for 38.1%.

Conclusions

In this study, mothers' parenting attitude (permission) and parenting efficacy were positively correlated, whereas their stress levels were negatively correlated with children's social skills. Children's social skills were influenced by mothers' parenting and marital stress levels and children's gender and birth order, as well as mothers' occupation. These results indicated that

mothers' stress level was an important factor influencing children's social skill; therefore, interventions to reduce mothers' stress levels should be provided. In addition, general characteristics such as children's gender and birth order and mothers' presence of occupation were also factors influencing children's social skills. Therefore, these differences should be considered in providing educational interventions on parenting.

Abstract

This study aimed to identify the relationships between body image perception and body esteem and sexual assertiveness of 296 female college students of university in Chungnam province: 150 nursing and 146 non-nursing students. Data were collected using a self-administered questionnaire from November 1 to September 10, 2018. The IBM SPSS 20.0 program was used to analyze collected data, including descriptive statistics, t-test, one way ANOVA (Scheffe test for post-hoc) and Pearson's correlation. Sexual assertiveness did not differ between nursing and non-nursing students. In nursing students, the higher the appearnace esteem, the higher the sexual assertiveness; however, differences in sexual assertiveness according to body image perception were not significant. In non-nursing students, the higher the appearnace esteem, attribution esteem, and body weight esteem, the higher the sexual assertiveness, which was also higher in students who underestimate their body than those who did not. These results indicated that appearance esteem of female students were related to sexual assertiveness. Therefore, various interventions to increase the appearance esteem and promote positive perception about their body should be provieded to increase the sexual assertiveness of female college students.

Keywords: *Body image, Body esteem, Sexual Assertiveness, Female college student.*

Introduction

Sexual assertiveness is defined as the ability to exprss one's feeling related to sexual desire and refuse unwanted sexual behaviror[1]. This definition implies that everyone has the right to make decisions regarding one's own bodies and sexual experience and shoud not be forced to do any unwanted sexual activities[2]. Sexual assertiveness can be expressed in various ways, such as initiating sex, rejecting unwanted sex, and insisting on condom use[2,3]. Men or women with high sexual assetiveness can maintain sexual health by appropriately expressing sexual needs and controlling sexual impulses[4], whereas, those with low sexual assertiveness can experience sexual problems such as unwanted pregnancy or sexually transmitted infections due to their inability to refuse unwanted sexual behavior or demand preventive sexual practices[2]. Therefore, sexual assertiveness is a vital element to protect and maintain sexual health in sexual situation[5].

Despite the importance of sexual assertiveness, women have difficulties in expressing their sexual desires and needs or rejecting unwanted sexual behaviors and are more likely to respond to unwanted sexual intercourse than men[6]. However, women can potentially play an active role rather than a passive role in their sexual relationships with men[7]. Therefore, various interventions should be provided for the improvement of women's sexual assertiveness to help them play a practically active role in sexual relations. To provide interventions for improvement of women's sexual assertiveness, it is

e-mail: kolee@smu.ac.kr

necessary to identify the influencing factors of women's sexual assertiveness. In previous studies, women's sexual assertiveness is related to various factors such as age, sexual intercourse experience, gender role stereotype, self-esteem, and emotional intelligence[6, 8]. However, studies on the effects of body image on sexual assertiveness have been limited because the attention is focused on the body during a sexual encounter[2, 8].

Body image is a subjective perception or evaluation of one's own body. Previous studies regarding relationships between body image and sexual health reported that women who are ashamed of their body and anxious about their apperance tend to feel more self-consciousness during sexual behaviors and more likely experience sexual problems[9].

In additions, these studies reported that women with poor body image initiate sex less and have more unprotected sex or risky sexual behaviors[2, 10]. However, whether these women think they have the right to sexual assertiveness and they have the conviction to act on that right remains to be elucidated[2]. In other words, whether these women's sexual behaviors are related to sexual assertiveness remains unknown. Therefore, relationships between women's body image and sexual assertiveness should be identified.

In this study, the relationship between female college students' body image and sexual assertiveness was examined to provide practical and efficient intervention for enhancing sexual assertiveness of female college students. In additions, in this study body image was measured using both a single-item questionnaire and the body esteem scale. Body image is often evaluated using uni-dimensional measures, but it consists of multiple dimensions[2]. Considering these facts, in this study body image was measured using both a single-item questionnaire on body image perception and the body esteem scale, which are multidimentionally constructed.

Method

Design and Subject: This survey study was conducted to identify the relationships between body image perception and body esteem and sexual assertiveness of female college students.

Participants consisted of 296 female students of university in Chungnam province: 150 nursing studnets and 146 non-nursing students.

Data were collected using a self-administered questionnaire from November 1 to September 10, 2018. Participants were fully explained on the purpose of this study, and the questionnaire was administered only if they agreed to participate in the study.

Measurements: Body image perception was measured using a single item subjective body image perception questionnaire designed to self-evaluate whether the female students was thin, normal, obese. Body image distortion was calculated by comparing body image perception and body mass index.

Body esteem was measured using a Park's[11] body esteem scale, a translated body esteem scale developed by Mendelson, Mendelson and White[12]. This scale consisted of 23 items and three subcategories (appearance, body weight, and attribution). Each items was rated on 5-point Likert scale (1-5), with higher score indicating higher body esteem. The internal consistency reliability was Cronbach's α = .82~90 in Park's[11] study and .82 in this study.

Sexual assertiveness was measured using a sexual assertiveness scale developed by Chae[8]. The scale was designed to measure the expression of one's needs and rejection of others' needs for seven sexual behaviors. This scale consisted of 18 items and each item was rated on 5-point Likert scale (1-5), with higher score indicating the higher sexual assertiveness. The internal consistency reliability at the time of development was Cronbach's α = .87 [8] and .88 in this study.

Data Analysis: The IBM SPSS 20.0 program was used to analyze the collected data. Descriptive statistics was used for general characteristics, body image related characteristics, body esteem, and sexual assertiveness. X^2-test, t-test, and ANCOVA were used to determine differences among general and body image related characteristics and body esteem and sexual assertiveness between nursing and non-nursing students. T-test and one way ANOVA were used to test differences in sexual assertiveness according to general and body image related characteristics. Pearson's correlation was used to identify the relationships between body esteem and sexual assertiveness.

Results

General Characteristics: Participants' general characteristics are shown in Table 1. Regarding their grade, nursing students had higher grades than non-

nursing students (x^2=21.79, p<.001). The experience of relationship (x^2=8.11, p=.004) and intercourse (x^2=7.15, p=.009) were higher in non-nursing students than in nursing students. Religion and time of the first relationship were not different between them.

Body image perception and body esteem: Body image perception and body esteem are shown in Table 2. As regards the difference in body image perceptions, nursing students were less likely to perceive their body shape as normal, but were more likely to perceive them as thin or obese than non-nursing students. (x^2=7.79, p=.020). Body mass index and body image distortion were not different between them. As regards the difference in body esteem, appearance esteem was higher in nursing students than non-nursing students (t=2.98, p=.003). Attribution and body weight esteem, the other two subcategories of body esteem, were not different between them.

	Sum	68.32±10.33	66.23±9.64	1.76 (.079)

Table 3. Sexual assertiveness (N=296)

Variables	Total	Range	Nursing Students (n=150)			Non-nursing Students (n=146)			F (*P*)
			Min	Max	M±SD	Min	Max	M±SD	
Sexual assertiveness	90	18~90	34	90	66.86±9.53	35	90	67.29±10.84	0.28 (.599)

Sexual Assertiveness: Sexual assertiveness is as shown in Table 3. Tables 1 and Table 2 show variables with statistically significant differences in general characteristics, body image related characteristics, and body esteem of nursing and non-nursing students. Therefore, the difference in sexual assertiveness between them was analyzed using ANCOVA to control these variables.

After controlling these variables, sexual assertiveness was not different between nursing and non-nursing students (F=.028, *p*=.599).

Sexual assertiveness according to general characteristics and body image perception: Sexual assertiveness according to the general characteristics and body image perception is shown in Table 4. In nursing students, sexual assertiveness was not different according to general characteristics and body image perception, whereas in non-nursing students, it was higher in those who underperceive than those who overperceive or right perceive their body image (F=4.28, *p*=.016).

Correlations between body esteem and sexual assertiveness: Table 5 shows the correlations between body esteem and sexual assertiveness. In nursing students, the higher the appearnace esteem, the higher sexual assertiveness (r=.18, *p*=.026), whereas in non-nursing students, the higher the appearnace esteem (r=.22, *p*=.008), attribution esteem (r=.20, *p*=.021), and body weight esteem (r=.20, *p*=.002), the higher sexual assertiveness.

Conclusions

This study showed that sexual assertiveness did not differ between nursing students and non-nursing students. This result indicated that interventions related to sexual assertiveness for female college students should focus more on their characteristics than their major. However, studies on differences in sexual assertiveness of female college students according to their major are insufficient. Therefore, futher studies are warranted.

Relationships between body image perception and body esteem and sexual asssertiveness of female college students were analyzed according to their major. In nursing students, the higer the appearance esteem among all body esteem variables,

Study of Multiple Genotypes in the *XPD* gene for A/C Lys751Gln and Lung Cancer in Samples from Baghdad–Iraq

Maiss Adnan Al-Ward[1], Mohammed Mahdi Jawad[1]

[1]*University of Baghdad, College of Education/Ibn Al-Haitham Department of Biology/Iraq*

Abstract

The chance of treating lung cancer is very low due to late diagnosis of metastasis. Therefore, the study of lung cancer and its related genetic patterns is of great importance in early diagnosis of infected individuals. This study analyzes the replication of A/C Lys751Gln polymorphisms of the XPD gene in the Iraqi population and the risk of its association with lung cancer. The results suggest that the heterozygous genotype Lys/Gln increases the risk of lung cancer, while Lys/Lys reduces at least the risk of lung cancer, WhileGln/Glngenotype does not show any significant increase in the risk of lung cancer. These types of studies help experts in timely diagnosis and use of effective remedial procedures especially in individuals who have patients from family members, relatives and couples in the case of endogamy . We hope that the association between these forms and lung cancer will be more clearly determined with statistical analyses in different populations as well as we suggest using this technique as a diagnostic biomarker in lung cancer patients. This study aimed to assess the effect of polymorphism on genotypes in the *XPD* gene on the susceptibility of lung cancer in Iraqi patients.

Keywords: *XPD, Lung Cancer, Iraq, Polymorphism, RFLP.*

Introduction

Lung cancer is the most common type of cancer and the leading cause of cancer-related deaths worldwide. According to recent statistics, there are more than 25.4 million cases of lung cancer that caused 1.2 million deaths during the period 1990-2016 [1].

In Iraq, lung cancer ranks second among the top ten types of cancer in Iraqi society, with 8.1% of all cancers diagnosed [2]. Lung cancer is a multivariate disease with both internal and external causes, the most common cause of which is smoking, which responsible for 90% of cases in males and 65% of cases in females[3]. This does not mean that non-smokers are safe from the disease, because internal factors as well as other environmental factors play an important role in causing the disease. One of the serious problems in lung cancer is its diagnosis in the late stages (Metastasis), which makes treatment difficult, so analysis of the agents of this type of cancer is of great importance [4].Lung cancer studies have shown a high rate of DNA damage and thus reduced repair capability and increased risk of lung cancer [5]. Studies have shown a defect in the DNA repair system and thus reduced repair capacity and increased risk of lung cancer[6,7].That means that lung cancer is a multi-cause disease (external and internal factors), different variables may affect the DNA repair gene and thus cause damage to the DNA.

One of the most important nuclear repair systems is Nucleotide excision repair (NER) [8],and one of the most effective genes in DNA repair is excision repair cross complementing (ERCC2), also known as the Xerodermapigmintosum group D (*XPD*) [9]. This gene encodes one of the important repair enzymes, and it is believed that the polymorphism in this gene is important in the risk of lung cancer. Studies have confirmed that individuals who have Lys751Gln polymorphism of the *XPD* gene have low repair ability for DNA damage.

The *XPD* gene is located on the long arm of chromosome 19 (9q13.32) and has a length of approximately 15KD. The protein encoder is a member of the TF11H, a 761 amino acid protein, and contains ATP dependent 5 'to 3' helicase activity of the damaged DNA chain and temporarily reduce the correlation[10, 11]. Studies suggest that polymorphisms in the XPD gene affect the efficiency and ability to repair DNA damage[12]. In Lys751Gln, the Glnamino acid in the codon CAG (C allele)is replaced by the primary Lys amino acid in AAG (A allele) [13]. Thus, polymorphisms in this gene alter the C-terminal terminal structure, which in turn increases the risk of lung cancer by altering the function of the XPD protein[14].

In Iraq there are no previous studies on the model *XPD* Lys751Gln and its relationship to lung cancer by RFLP method, and therefore the study was conducted, and aims to verify its relationship with lung cancer.

Materials and Method

Samples: The current study included 63 Iraqi patients diagnosed with lung cancer ranging in age (30-80) years, including 49 smokers and 14 non-smokers, as well as 24 healthy people as a control group. Blood samples were collected from the visitor patientsat the Teaching Oncology Hospital in the Medical City/ Baghdad for the period from September 2018 to January 2019. After obtaining the moral permission from the hospital and the patients to conduct the study with the help of the consultant doctors, 3 ml of venous blood using by a disposable syringein sterile conditions are kept in tubes containing EDTA at a temperature of -20°C until use.

Genomic DNA Extraction: Blood samples were collected with the aim of extracting DNA using the gSYNC^{TM} DNA extraction Kit from Taiwanese company Genaid.

Genomic DNA: 5 µl of extracted DNA mixed with loading dye and loaded in the wells of 1.5% agarose gel at 75 V for an hour. The results were documented using a UV source at a wavelength of 350 nm [15].Determination of the required segment of the studied genes (target segment) accomplished by using polymerase chain reaction technique,the segment of the XPD gene was 476 bpappeared by using a pair of specific primers according to[16] (Table 1), from Bioneer (Korea) in a lyophilized form. A certain volume of nuclease-free water was added to primer tubes depending on the concentration of the primerrecommended by the leaflet accompanied and the reaction started in the PCR machine according to the program (Table 2) by mixing 5 µl of Pre-mix solution of the kit (Bionner-Korea) with 3 µl of extracted DNA, 2 µlof each primer and 13µl of Nuclease-free distilled water to make the volume up to 25microliters.

Determination of purity and concentration of DNA: DNA samples centrifuged by the centrifuge device to ensure their homogeneity. The estimation was performed using the Nanodrop device, 2 microliters of the extracted DNA placed in the space assigned to the device and the order of measurement is given and recorded ,which ranged from 1.5-1.8 ng per microliters to all samples.

Table 1: Sequence of the pair of pylons used in this study.

Reference	Product size	Sequence (5' - 3')		gene
(16)	476 bp	5'-ATCCTGTCCCTACTGGCCATTC-3'	Forward	XPD
		5'-CCACTAACGTCCAGTGAACTGC-3'	Reverse	

Table 2: Optimal conditions for PCR reaction

No. of cycles	Time	Temperature (C°)	Steps
1	5 minute	94	Initial Denaturation
3	30 second	94	Denaturation
	30 second	62	Annealing
	30 second	72	Extention
1	5 minute	72	Final Extention

Results and Discussions

Analysis of the results of polymerase chain reaction: The molecular size of the PCR product was determined in comparison to (25-2000bp) DNA Molecular weight marker from Bioneer (Korea), 5 µl of the product and 5 DNA ladder on the 2% agarosegel. The voltage was 80V for an hour, and the results of the electrophoresis using the gel imaging unit was photographed under UV light, the molecular weights were measured and the band that magnified by PCR techniqueis in 476 bplocation (Fig. 1).

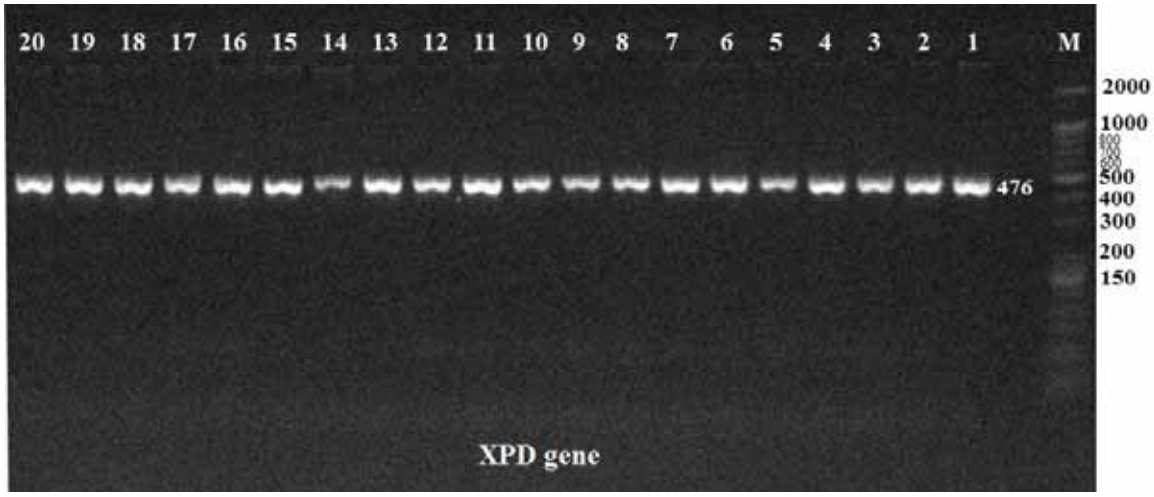

Figure 1: band resulting from amplification of a segment of the *XPD* gene for a number of studied samples (M) Molecular weight marker 25-2000bp from Bioneer/Korea, 1-20are samples studied, size of the amplified fragment is 476 bp.

Enzymatic digestion: 10 microliters of PCR product were taken to be cut by1 µl of *Pst* I restriction enzyme after adding the other additions came with the enzyme kit,the mixture incubate at 37 °C for 1 h and electrophorsed on 3% agarose gel and 80 volts for 1.5 hours.

There is one site to identify the enzyme *Pst* I in allele A, so the allele A is expected to display two bands of DNA in sizes 105, 371 bp, while three bands were expected to appear in the C allele due to the site of the additional cutting. These bands were 63, 105 and 308 bp respectively. Individuals with different alleles of zygote were expected to exhibit a combination of two different alleles (Fig. 2).

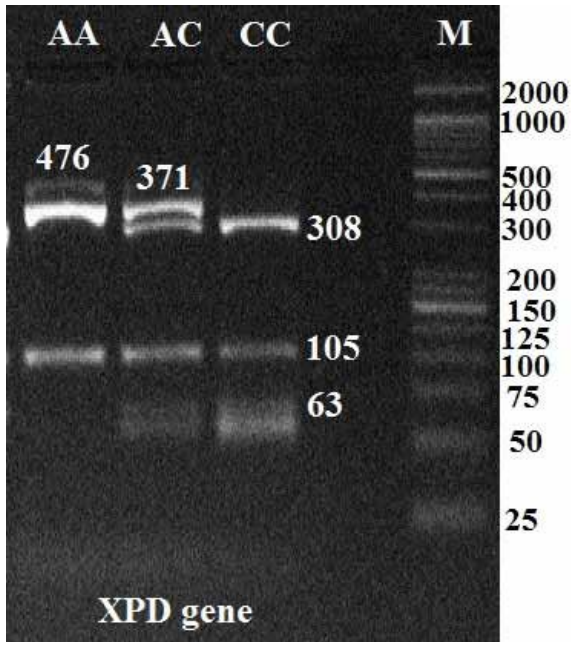

Figure 2: Electrophoresis of PCR-RFLP amplification products using the PstIto analyze Lys751Gln A/C Genotyping, M molecular weight marker 25-2000 base pairs from Bioneer/Korea, CC, AC and AA Genotypes resulting from cutting after amplification of a fragmentof the XPD gene by PCR technology.

Statistical analysis: The statistical analysis system SAS (2012) was used to analyze the various factors in the study. The Chi square law was used to find the range of equilibrium between observed and expected samples. The Hardy–Weinberg equilibrium was used in the population genetics to investigate whether the samples represented the community in real terms. [17].

Distribution of XPD (Lys751Gln) polymorphisms in samples: The genetic polymorphism of a fragment of XPD gene was observed in three hereditary structures (CC, AC, and AA) in patients, and in the absence of XPD genotypes CC in control sample. The homozygous genotype AA recorded the higher percentage in control (53.88%) against that of patients (30.16%)and that of a significant difference (P <0.01). The percentage of the heterozygous genotype AC is (63.49%),and that is higher than in control (46.15%) with a significant difference (P <0.01), while the homozygous genotype GG was recorded in patients (36.35%)and not noticed in control.

The frequency percentage of A allele was (0.62%) in patients and (0.79%) in control, while the frequency percentage of allele C in patients was (0.38%) and in control was (0.21%),and the results of observed values in patients were not consistent with expected values in Hardy-Weinbergequilibrium. In addition, the odds ratio (OR) for the genotype AA was (1.24) and the ratio of (OR) for heterozygous AC genotype was (1.80) and for the homozygous CC was (0.438) (Table3).

Table 3: Distribution and allele frequencies of XPD gene in control and lung cancer groups.

Genotype	Groups		Chi-Square (X^2)	P-Value (O.R.)
	Control No (%)	Lung cancer No (%)		
AA	14 (53.85%)	19 (30.16%)	8.28**	0.0057(1.24)
AC	10 (6.15%)	40 (63.49%)	6.19**	0.0091 (1.80)
CC	0 (0.00%)	4 (6.35%)	2.63 NS	0.072 (0.438)
Total	24	63	-	-
Allele frequency				
A	0.79	0.62	-	-
C	0.21	0.38	-	-

**(P<0.01), NS: Non-Significant

According to statistical analysis, the risk of lung cancer in individuals with polymorphism Lys751Gln (Odd Ratio = 1.80) is greater than that of Lys/Lys genotype, where Gln/Glngenotype is not associated with the risk of lung cancer.

The current study shows that there is a significant difference between patient groups and control in the distribution of AC genotype polymorphism, and C alleles frequency in the Iraqi patient group is more than the control group, so we suggest that this difference could be due to the presence of allele C along with allele A in AC, And molecular interaction between them. These results are consistent with Zhan *etal*.2010[18],who suggested that the AC genotypeof the XPD gene was associated with lung cancer risk and that the C allele in AC genotype of XPD gene was an increased risk factor for developing lung cancer in the meta-analysis studies,as well as consistent with the results of Feng*etal*. 2011[19], who suggested that the AC genotype may contribute to the susceptibility of lung cancer and the high risk of infection with the presence of C allele significantly. It is also consistent with the results of Motovali-Bashi*etal*. 2010 [16], which showed that the proportion of the AC gene was higher in patients compared to the rest of people and that the AA genotype is probably reduces the seriousness. According to a study conducted by Liang *etal*.[20], who mentioned that individuals who have a heterozygous CC genotype, show lung cancer about 2.7 times more than individuals who have an AA genotype.

Conclusion

This study indicates that most of the infections diagnosed occurred for Lys/Gln AC patients. Lys/Lys individuals is likely to reduce its risk with them.

Assessment of Risk Factors of Asthma in Health Institutions in Maysan Governorate, Iraq

Ali Abdulwahed AbdulJabbar[1], Buthaina Ateyah Rashid[2]

[1]M.Sc. Student, [2]Assist Prof., Middle Technical University College of Health& Medical Technology, Baghdad, Iraq

Abstract

Background: Asthma is a common chronic lung disease in which the airways (bronchi) become inflamed and are abnormally sensitive to certain triggers. Asthma can affect people of all races and ages, and although there is no known cure, there are many ways to control it. The symptoms of asthma include coughing, shortness of breath, wheezing and chest tightness.

Materials and Method: This is A case-control study conducted in Consultation Center for Chest and Respiratory Diseases at Al-Sadr Teaching Hospital in Maysan Governorate Data was collected over a period of five months between the 1st of November 2019 to the 1st of April 2020.

Results: The commonest risk factors that had been found causes asthma in cases was family history of asthma with OR=5.127,CI=(2.77-9.49), upper respiratory tract infection with OR=5.059,CI=(2.29-8.76), active smoker with OR=2.145,CI=(1.18-3.91)Occupational exposure to dust with OR = 4.660,CI= (2.68-8.10), skin allergy with OR =2.77,CI=(1.28-6.03).

Conclusion: Significant association was found between **(**Family history of asthma, upper respiratory tract infection, active smoking,occupational exposure to dust, chemical, fumes, and gases, allergies and the used of NSAIDs before the onset of asthma) and asthma in adults in maysan governorate.

Keywords: *Risk Factors; Asthma; chronic lung disease; Maysan.*

Introduction

Asthma is a common chronic respiratory disease and is a major public health problem worldwide, and affects people of all races and genders. Reports indicate that the number of asthma sufferers worldwide may exceed 334 million, according to a report published by the World Asthma Network in 2014[(1)].Many studies have shown that the prevalence of asthma varies between countries and within countries, and is directly proportional to different allergies, where different lifestyles are adopted and societies become civilized, and this trend is expected to continue during the next two decades[(2)]. For people who suffer from asthma, it can cause them a major disability and affect the quality of life significantly[(1)(2)]. The significant increase in the prevalence of asthma and other allergies (for example, eczema) cannot be explained over the past several decades by relying on genetic factors alone, and this leads to an increased focus on other risk factors such as environmental exposure, for example, and it is expected that cases will rise Asthma to over 400 million cases globally in 2025[(3)]. due to climate change, increased exposure to air pollution, urbanization, changing the immune response and changing lifestyle[(3)(4)]. in the UK receiving approximately 4.3 million adults treating from asthma[(5)].

Aim of Study: To assess the major risk factors of asthma in adult in health institutions in maysan governorate.

Patients and Method

A case-control study was conducted in Consultation Center for Chest and Respiratory Diseases at Al-Sadr Teaching Hospital in Maysan Governorate(one of the 18Iraqi governorate located in south of Iraq the number of persons 1million and characteristics with Marshes and oil) It is a center for the diagnosis and treatment of respiratory diseases and is located in the center of the city of Amara and provides care and treatment to respiratory patients from all its districts and aspects of Maysan Governorate. The center provide services to average 50 patients daily with respiratory diseases of them about 2-3 patients with asthma daily for 5 days in a week. The daily center activities include history taking, clinical examination, laboratory investigations, management, the follow-up to asthma patients, health education, also different respiratory cases for management, and follow up. Data was collected over a period of five months between the 1st of November 2019 to the 1st of April 2020.

Statistical Analysis: Analysis of data was carried out using the available statistical package of SPSS-25 (Statistical Packages for Social Sciences- version 25).

Finding: The results in table 1 showed the distribution of age and gender among cases and controls and there was no statistically significant difference between the two groups (p >0.05) the higher percentage of cases was in age groups (40-49) years (27.5%). the higher percentage of controls was in the age group (30-39) years (30.8%). Predominantly males (36.7%) and females (63.3%) in both cases and controls.

Table (1): Distribution of cases and controls according to age and gender.

		Asthmatic patients		Controls		P value
		No	%	No	%	
Gender	Male	44	36.7	44	36.7	
	Female	76	63.3	76	63.3	
Age (years)	<20 years	7	5.8	4	3.3	0.356
	20---29	12	10.0	21	17.5	
	30---39	30	25.0	37	30.8	
	40---49	33	27.5	27	22.5	
	50---59	20	16.7	18	15.0	
	=>60 years	18	15.0	13	10.8	

The results in (table 2) shows persons that used electrical heating system protected from asthma with low significant association OR=0.553,CI=(0.32-0.95). Persons that use oil heating system at risk (5 times) to have asthma with highly statistical significant OR =4.846,CI=(2.40-9.80). Regarding dampness on the wall, the percentage of the cases was 73.3%, and controls were 65.0%, with no statistical differences between the two groups (p-value= 0.162).). Regarding household pets, the percentage of cases was 19.2% and controls were 15.0% with no statistical significant P-Value =0.162. persons that allow pets in bed at risk 5 times to have asthma with significant association OR=5.46,CI=(1.24-24.09).

Table (2) : Distribution of cases and controls according to heating system inside the house, dampness on the wall and household pets.

Type of heating system inside the house		Asthmatic patients		Controls		P value	OR (95% CI)
		No	%	No	%		
Electrical	Yes	34	28.3	50	41.7	0.030*	0.553 (0.32-0.95)
	No	86	71.7	70	58.3		

Type of heating system inside the house		Asthmatic patients		Controls		P value	OR (95% CI)
		No	%	No	%		
Oil	Yes	108	90.0	78	65.0	0.0001*	4.846 (2.40-9.80)
	No	12	10.0	42	35.0		
Is there dampness on the wall	Yes	88	73.3	78	65.0	0.162	1.481 (0.85-2.57)
	No	32	26.7	42	35.0		
You have household pets	Yes	23	19.2	18	15.0	0.391	1.344 (0.68-2.64)
	No	97	80.8	102	85.0		
Allow pets be in bed	Yes	12	52.2	3	16.7	0.019*	5.46 (1.24-24.09)
	No	11	47.8	15	83.3		

This table shows the persons that have a family history of asthma at risk 5 times to have asthma compared with none with highly significant association OR=5.127,CI=(2.77-9.49). the high percentage of family history in cases was 18.3% in mother, and in controls was 7.5% in sister.

These results shows persons that have upper respiratory tract infection at risk five times to have asthma with highly significant association OR=5.059,CI=(2.29-8.76). this table shows persons that have an infection from 6-11 months at risk 8 times to have asthma with highly significant association OR=8.25,CI=(1.80-37.91), persons that have infections =>12 months at risk 4 times to have asthma with highly significant association OR=4.29,CI=(1.48-12.41).

Table (3) : Distribution of cases and controls according to family history and upper respiratory tract infection.

		Asthmatic patients		Controls		P value	OR (95% CI)
		No	%	No	%

The results in table 4 show persons that are an active smoker before the onset of asthma at risk 2 times to have asthma from non-smoker with significant association OR=2.145,CI=(1.18-3.91). the high percentage of cigarettes packet/day was 56.4% of cases and 72.7%of controls were in 1 packet/day, With statistically no

significant (p-value = 0.433). the high percentage of the duration of smoking of cases was 43.6% in duration (=>15 years), for controls were 40.9% in duration (10---14 years). Regarding second-hand smoke, the percentage of cases was 50.8% and controls were 49.2% with statistically no significant (p-value = 0.796).

Table (4) : Distribution of cases and controls according to smoker and second hand smoke.

		Asthmatic patients		Controls		P value	OR (95% CI)
		No	%	No	%		
Smoker before onset asthma	Yes	39	32.5	22	18.3	0.012*	2.145 (1.18-3.91)

Discussion

Regarding the age, the results in this study demonstrated that the higher percentage was in the age group between (40-49) years with no significant association (p-value =0.356). it disagrees with the study that reported by Abdulhussian, 2015 in Basrah that found most of the study samples were among age group (30-44) years with no significant association (p-value =0.730)[6]. In the current study, this results demonstrated that the higher percentage of gender in females 63.3% in compared with males 36.7%.which is in agreement with the result that done by Abdulhussian, 2015 in Basrah that found most of the study samples were among females 62.5% in compared with males 37.5%[6].

Regarding the type of heating system inside the house the results of current study shows that the higher percentage was 90.0% in cases and 65.0% in controls were oil, which it disagrees with the result of study

done by Esmaeil Idani,2019 in Iran which found that the higher percentage of cases was 98.3% , and controls were 98.4% were Gas[7] . This disagreement may be due to the type of fuel available in Iraq compared to other countries, Also, it may be due to economic and environmental matters.

In this study regarding dampness on the wall, this result demonstrate that the percentage of the cases was 73.3%, and controls were 65.0%, with no statistical differences between the two groups (p-value= 0.162). which is in agreement with the result of study done by Esmaeil Idani,2019 in Iran that found that the percentage of cases was 51.1% and controls were 49.2% with no statistical differences between the two groups (p-value= 0.433)[7].

regarding household pets, the current study demonstrate that the percentage of cases have household pets was 19.2% and controls were 15.0%, and this results shows the percentage of allowing pets in bed was 52.2% in cases and 16.7% in controls with statistical significance (p-value = 0.019).which is in agreement with the results of study done by Esmaeil Idani,2019 in Iran that found the percentage of cases have household pets was 8.5%, and controls were 7.9%, and the percentage of allowing pets in bed was 2.8% in cases and 0.9% in controls with statistical significance (p-value <0.001)[7].

The present study demonstrate that the percentage of cases have family history of asthma was 47.5% and for controls 15.0%,which is in agreement with results of study that done by Elfaki NK, 2017 in Saudi Arabia. That found that the percentage of cases have family history of asthma was 66.8%. and for controls 40.2%[8].

The current study demonstrate that the percentage of cases have upper respiratory tract infection was 71.7%, and for controls were 32.5% with highly statistically significant (OR= 5.253 , CI=3.03-9.11) . which is in agreement with the results of study that reported by Al-Mazam, A., 2001 in Saudi Arabia that found that the percentage of cases have upper respiratory tract infection was 61.8%, and for controls were 13.6% that found to be an independent risk factor for bronchial asthma (OR=10.5, CI=5.11-21.89)[9].

Regarding active smoker this study shows that the percentage of the active smoker was 32.5% among cases and 18.3 among controls ,which is in agreement with the results of study done by Elfaki, N. K., 2017 in Saudi Arabia that found the percentage of cases are active smokers was 26.6% and for controls were 22.8%[8].

Regarding second-hand smoke, this study shows that the percentage of cases was 50.8%,and for controls were 49.2%. which is in agreement with the results of study done by Elfaki, N. K., 2017 in Saudi Arabia. that found the percentage of cases was 66.3% and for controls were 56.0%[8].

Regarding BMI(Body Max Index) this study shows that the higher percentage of cases was 37.5% were overweight (25-29.9), and the lower percentage of cases was 15.8% were obese II(=>35). which is in agreement with the results of study done by Muhammed, S. M et al,2012 in Baghdad which found that the higher percentage of asthmatic patients was 45.7% were overweight (25-29.9). and the lower percentage of cases was 2.3% were obese II(=>35)[10]. But, it is disagreed with the results of study done by Rönmark, E.et al,2005 in northern Sweden that found that the higher percentage of cases was 42.1% were normal (20-24.9)[11]. This disagreement may be due to a different lifestyle in Iraq than in other countries.

Conclusions

Statistically significant was found between the type of heating system inside the house and asthma in adults. Also, between patients who had a family history of asthma and asthma in adults. So Positive association was found between upper respiratory tract infection and asthma in adults.

Abstract

Breast cancer patients need coping mechanisms to adapt to changes due to breast cancer. The constructive coping mechanism is very influential on the attitude, response, decision making towards breast cancer management, and quality of life. The study aimed to determine the determinants of coping mechanisms of breast cancer patients in Sidoarjo Regency, Indonesia. The sample size was 98 breast cancer patients. The variables analyzed included coping mechanism, age, educational, marital, work, time diagnosed, genetic, stage of cancer, therapy, social support, and spiritual need. The results found that breast cancer patients with higher education had a 51.200 times chance compared to breast cancer patients with no education to have adaptive coping mechanisms. Therapy for breast cancer patients has a positive effect on adaptive coping mechanisms. Social support has a positive influence on breast cancer patients to have an adaptive coping mechanism. The higher the social support provided, the more adaptive coping mechanism is for breast cancer patients. Tree variables have proven to be significant as determinants of coping mechanisms among breast cancer patients in the Sidoarjo Regency, namely education, therapy, and social support.

Keywords: *Breast cancer, coping mechanisms, spiritual needs, social support, education.*

Introduction

Breast cancer is a malignant tumor originating from breast cells. Breast cancer can originate from cells that produce mammary glands (lobular), glandular ducts from lobular to nipple (ducts), and supporting breast tissue that surrounds the lobular, ducts, blood vessels, and lymph vessels, but does not include breast skin[1].

Breast cancer is the highest type of cancer in women in the world. The incidence of breast cancer increased from 26 per 100,000 to 38 per 100,000 women. This prevalence is above cervical cancer with a record of 16 per 100,000 women[2]. In Indonesia, the prevalence of cancer is 1.4 per 1,000 population and is the 7th leading cause of death (5.7%) of all causes of death. The estimated incidence of breast cancer in Indonesia is 40 per 100,000 and cervical cancer 17 per 100,000 women[2]. While breast cancer incidence in East Java was ranked first in Indonesia[3].

Cancer diagnosis and management are stressors that affect all aspects of a patient's life. Changes occur in the physical, psychological, social, and spiritual of the patient[4]. Diagnosis and treatment of breast cancer is the highest stress, and causes of psychosocial disorders. Breast cancer patients face uncertainty and fear of cancer diagnosis, management, and recovery. Individuals diagnosed with breast cancer generally face a variety of invasive medical procedures with many potential negative side effects (eg pain, nausea, vomiting, lymphedema, hair loss). High-stress levels can cause long-term negative effects on psychosocial breast cancer patients[5]. Other psychological reactions that commonly occur due to a diagnosis of breast cancer are distress,

e-mail: agung.dwi.laksono-2016@fkm.unair.ac.id

shock, impaired self-concept, anxiety, depression, loss of control, helplessness, difficulty concentrating, despair, loss of zest for life. The psychological impact of breast cancer 80% causes the patient to distress, 16% feel close to death, 3% angry, and 1% can accept the condition[6]. The impact of breast cancer also results in physiological incapability, psychological disequilibrium, social relationship misbehavior, spiritual values disparity, and life of courage[7]. These changes will have an impact on the quality of life of breast cancer patients.

Breast cancer patients need coping mechanisms to adapt to changes due to breast cancer. The constructive coping mechanism is very influential on the attitude, response, decision making towards breast cancer management, and quality of life[8]. Identifying the factors that influence coping mechanisms is important. Some factors that influence coping mechanisms are age, sex, perception of disease, personality, and social and cultural conditions, spiritual needs, social support, and demographic factor[8,9]. Previous research found that the constructive coping mechanism is very influential on the quality of life of breast cancer patients. Identifying factors that influence the coping mechanism for breast cancer patients can provide specific interventions to overcome psychosocial problems that occur in breast cancer patients[10]. Based on the background description, the study aimed to determine the determinants of coping mechanisms of breast cancer patients at SidoarjoRegency, Indonesia.

Materials and Method

This study was an observational analytic study with a cross-sectional design. The study population was all patients who had been diagnosed with breast cancer by a doctor in Sidoarjo Regency. The number of samples was 98 patients with a diagnosis of breast cancer. The dependent variable is the coping mechanism, which consists of adaptive and maladaptive coping mechanisms. The independent variables are age group, educational level, marital status, work status, time diagnosed, the genetic, stadium of cancer, therapy, social support, and spiritual need. The final stage was analyzed multivariate with binary logistic regression.

Coping mechanisms are cognitive and behavioral changes that are constant to overcome certain internal or external demands that are tiring or exceed individual sources[11]. The coping mechanism can be described as handling related to problems and situations[12]. An adaptive coping mechanism is a coping mechanism that supports the function of integration, growth, learning and achieving goals. Adaptive coping mechanisms include talking to others about the problem being faced to find alternative solutions, trying to find more information about the problem being faced, praying, doing physical exercises to reduce the tension of the problem, making various alternative actions to reduce the situation, and feel confident that all will return to stable, take lessons from past events or experiences. Maladaptive coping mechanisms are coping mechanisms that inhibit the function of integration, solve growth, reduce autonomy, and tend to control the environment. Maladaptive behavior includes aggressive behavior and withdrawal. physically and psychologically individuals consciously leave the environment that is the source of stressors such as individuals fleeing from sources of stress[13].

Social support is any form of effort provided by others, close relatives, breast cancer patient peer groups in adapting to their illness, which includes emotional, judgment, information, instrumental. Emotional support is any effort given by family and closest people to breast cancer patients through feelings of care, attention, affection, and love, so that breast cancer patients feel comfortable. Appraisal support is any form of support carried out by family and loved ones through positive expressions, positive support for breast cancer patients. Information support is support from health workers and families to breast cancer patients through the provision of information about the disease so that patients understand the disease and its condition. Instrumental support is the support given by the family in the form of material to breast cancer patients.

Spiritual needs in sufferers of chronic diseases include relationships, peace, meaning/purpose, and transcendence, which can be related to the psychosocial, emotional, existential, and religious needs that underlie them. Spiritual needs are the need for trust, the need to express personal trust, the need to maintain the spiritual practice, and trust in God. Questionnaire to measure the spiritual needs of patients, using the Spiritual Needs Questionnaire[14].

Results and Discussion

Table 1 displays descriptive statistics of breast cancer patients in SidoarjoRegency, Indonesia. Based on the age group, the two types of coping mechanisms are dominated by patients in the 46-55 age group. Based

on education level, breast cancer patients who are maladaptive in the coping mechanism are dominated by patients who have primary education, while breast cancer patients who are adaptive in the coping mechanism are dominated by patients who have higher education, secondary education. Based on marital status, the two types of coping mechanisms are dominated by married patients. Based on work status, both types of coping mechanisms are dominated by patients having work.

Based on time diagnosed, breast cancer patients who are maladaptive in the coping mechanism are dominated by patients diagnosed for less than 1 year, while adaptive breast cancer patients in the coping mechanism are dominated by patients who are diagnosed for more than 1 year. Based on genetic variables, both types of coping mechanisms are dominated by patients who have breast cancer lineage. Based on therapy, breast cancer patients who are maladaptive in the coping mechanism are dominated by patients who have not done therapy, while breast cancer patients who are adaptive in the coping mechanism are dominated by patients who have finished doing therapy.

Based on social support, breast cancer patients who are maladaptive in the coping mechanism are dominated by patients who have low social support, while breast cancer patients who are adaptive in the coping mechanism are dominated by patients who have social support medium. Based on spiritual needs, breast cancer patients who are maladaptive in the coping mechanism are dominated by patients who have spiritual needs medium category, while breast cancer patients who are adaptive in the coping mechanism are dominated by patients who have spiritual needs high category.

Table 2 shows the results of the binary logistic regression of coping mechanisms among breast cancer patients. Based on the level of education, it appears that breast cancer patients with higher education have 51.200 times chance compared to breast cancer patients with no education to have an adaptive coping mechanism (OR 51.200; 95% CI 1.575-1664.335). The results of this analysis inform us that the level of education has a positive influence on coping mechanisms that are adaptive for breast cancer patients.

Note: *p<0.05; **p<0.01; ***p<0.001.

The better level of education makes breast cancer patients more receptive to the conditions that are undergoing higher education are more likely to be able to adapt to breast cancer, this is possible because access to sources of information is easier to do. These results are consistent with research conducted in Iran showing that higher education is more likely to be able to adapt to breast cancer, this is possible because access to information sources is easier to do. This finding is in line with several previous studies in Norway proving that educational level was the most important contributor to social support, Educational was positively related to instrumental-oriented coping[15].Previous studies have suggested that education are often found to have a positive impact on various programs in the health sector[16–19].

The breast cancer patient who is undergoing therapy has a 12.467 times chance compared to breast cancer patients who have not undergone therapy to have an adaptive coping mechanism (OR 12.467; 95% CI 1.429-108.736). Breast cancer patients who have finished therapy have a 14.958 times chance compared to breast cancer patients who have not yet undergone therapy to have an adaptive coping mechanism (OR 14.958; 95% CI 2.213-101.105). The results of this analysis inform that therapy for breast cancer patients has a positive influence on adaptive coping mechanisms.

Therapy provides a calming effect for breast cancer patients. Breast cancer patients who have not been and are undergoing chemotherapy experience anxiety, depression, nausea, vomiting tend to ooze in their disorder. Breast cancer patients who have finished undergoing chemotherapy using coping mechanisms are more effective. The coping approach is mainly used by patients who see their disease as a challenge. Behavioral and cognitive aspects of coping decrease with the level of difficulty experienced by individuals[9].

Breast cancer patients who received medium category social support had a 7.561 chance compared to breast cancer patients who received low category social support to have an adaptive coping mechanism (OR 7.561; 95% CI 1.469-38.916). Breast cancer patients who received high category social support had 225.419 times the chance of breast cancer patients who received category low social support to have an adaptive coping mechanism (OR 225.419; 95% CI 14.154-3589.974). The results of this analysis inform that social support has a positive influence on breast cancer patients to have adaptive coping mechanisms. The higher the social support provided, the more adaptive the coping mechanism is for breast cancer patients' adaptive coping mechanism breast cancer patients.

This finding reinforces the findings of previous studies that took the same theme. Other studies show social support for breast cancer patients not only directly increases emotional well-being, but also indirectly influences emotional well-being by influencing coping strategies[10]. Research in Norway also shows that social support is considered an undeniable resource when dealing with difficult life situations. Social support was positively related to instrumental-oriented coping and emotion-focused coping[15].

Conclusions

Based on the results of the analysis found that 3 variables prove to be significant as determinants of coping mechanism among breast cancer patients in

Sidoarjo Regency, Indonesia. The three determinants are education level, therapy, and social support.

Application of Care Bundle Approach for Preventing Device Associated Infections: A Training Program for Pediatric and Neonatal Nurses

Amal M. Ibrahim[1], Safy S. Al-Rafay[2], Hyam R. Tantawi[2]

[1]Specialist Infection Control, Ain Shams University Specialized Hospital, Cairo, Egypt,
[2]Professor of Pediatric Nursing, Faculty of Nursing, Ain Shams University, Cairo, Egypt

Abstract

Background: Care bundle implementation as a small set of evidence-based interventions together was used in this study for giving better outcomes for defined nurses; caring for pediatric and neonatal patients are faced with increased risks of the device-associated infections and life-threatening conditions during exposure to many invasive devices in intensive care units.

Objective: To assess the influence of the application of care bundle approach training program on pediatric and neonatal nurses for preventing device-associated infection.

Methodology: A quasi-experimental study was used. This study was conducted in pediatric and neonatal intensive care units at Ain Shams University Specialized Hospital (ASUSH) in Cairo.A convenient sample of 70 nurses were involved for data collection by two method; **First:** An interviewing questionnaire divided into two parts: Part 1. Nurses demographic data, Part 2. Assessment of nurses' knowledge. **Second:** Observation checklist for assessing nursing performance regarding the bundle of care.

Results: Less than one quarters (21.40%) of the studied nurses had satisfied knowledge preprogram intervention, compared with more than 85.70% of them has a satisfied post-program intervention regarding the level of total knowledge about the bundle of care;Also, 15.70%of the studied nurses had competent total performance regarding the bundle of care pre-program intervention compared with nearly 72.9%of them had a competent performance post-program intervention.

Conclusion: Application of training program reported remarkable improvement in pediatric and neonatal intensive care nurses' knowledge and performance toward the care bundle approach for preventing device-associated infection.

Keywords: *Pediatric and neonatal intensive care, bundle of care, Nurses performance.*

Introduction

The pediatric and neonatal patients are faced with increased risks of the Device Associated Infections (DAIs) and life-threatening conditions because of the low immunity to many pathogens, and exposure to many invasive devices, parenteral nutrition, prolonged hospitalization ,and persistent processes in Intensive Care Unit (ICU) are among the risk factors associated with Hospital Acquired Infection (HAI)[1].Compliance of pediatric nurses in pediatric and neonatal ICUs with the Standard Precautions (SPs) and the bundle of care an efficient means to prevent and control (DAIs)[2]. The main types of HAIs are DAIs, including the following: Ventilator-Associated Pneumonia (VAP), Central Line-Associated Bloodstream Infection (CLABSI), and Catheter-Associated Urinary Tract Infection (CAUTI)[3].

e-mail: amal.ibrahim10@yahoo.com

Invasive devices in pediatric ICUs (PICUs) are the utmost common threat factors for HAI and applying the bundle strategy is recommended for the avoidance of invasive device- related infections. Prevention Control (PC) bundles have been implemented includes three to five key Infection Prevention Control (IPC) elements based on evidence or coming from well-accepted guidelines[4]. So, ICUs guidelines will review important considerations for infection prevention specifically for VAP, CLABSI, and CAUTI.

Bundles of care are practicable, are easy to implement and adhere to, and are effective in reducing the HAI rates constitutively across the world including developed and developing countries. Following evidence-based bundles that are tailor-made to suit the performance[5].

Pediatric and neonatal nurses in ICUs are in the best position to apply evidence- based guidelines into the performance as they are at the pediatric patient's bedside 24 hours daily providing nursing care and therefore performs a vital role in the prevention of HAIs. Nevertheless, pediatric nurses need to have an awareness of the problem as well as knowledge on current research evidence to adhere to such practices lack of knowledge[6].

In Egypt, Device Associated Infections (DAIs) was 24.5% per 1,000 ICU-days. (VAP) rate was 15.8/1,000 ventilator days, (CLABSI) rate was 6.8/1,000 central line days, and (CAUTI) rate was 6.3/1,000 urinary catheter days in different developing countries[7]. These infections are potentially preventable and can be reduced through implementing care bundles. Bundles are sets of evidence- based interventions, which are designed to improve pediatric patient's health and prevent complications from (DAIs)[8].Bundles of care are commonly practical tools in ICUs consist of three to a maximum of six evidence-based 'elements,' for patients in the health care setting. The elements should be practical together to all pediatric and neonatal patients. The power of bundling is to confirm that all elements function together in every pediatric patient to advance pediatric patient health outcomes[9].

Aim of the Study: This study aimed to assess the influence of the application of care bundle approach training program on pediatric and neonatal nurses for preventing device- associated infection

Methodology

Design of Study: A quasi-experimental design was used to achieve the aim of this study. The study was conducted in pediatric and neonatal ICUs (PICU and NICU) at Ain Shams University Specialized Hospital (ASUSH) in Cairo, Egypt. The PICU unit consists of four units (unit zero, one, two, and three). Unit zero consists from two beds for hemodialysis patients, unit one consists of four beds for post-operative cardiac surgery, unit two consists from four beds, and unit three divided by glass partition into two parts and each part consists of five beds, the total beds in the two units is 20 beds.The NICU consists of one unit divided by glass partition into two parts, and closed room equipped by one incubator for isolation cases, the total incubators inthe unit are fifteen incubators one of them is portable. Additionally, both units (PICU and NICU) are equipped with separate ventilator and monitor for each incubator or bed.

Sampling: A convenient sample of all available nurses (70 nurses) from the above-mentioned settings regardless their educational levels,or years of experience, over a period of 6 months. Forty- five nurses from the PICU and 35 nurses were from the NICU.

Tools for data collection: After reviewing of the recent related literatures was adapted from**De Neef *et al.* (2019), Holzmann (2019), Mack *et al.* (2017), The Egyptian Ministry of Health and Population (2016)[10,11,12,13].** and it include two tools were used for data collection as follows:

First tool: An interviewing questionnaire: It was designed by the researchers. This tool was written in Arabic language and divided into two parts.

Part 1: Nurses' characteristics such as: Age, gender, qualification, years of experience, and training of bundle of care for preventing DAIs.

Part 2: Nurses knowledge assessment about DAIs bundle of care pre/post -test:

This part was completed by nurses before and after the program implementation, it was comprised of (51) questions distributed on:

Knowledge about HAI: (6) questions concerned with: Definition of HAI, types of microbes, causes of HAI, modes of infection, the effect of premature patient on HAI, and component of the chain of infection.

Knowledge about SPs: (13 questions) related to: Definition of SPs, measures of SPs, hand hygiene

(types of hand hygiene, types of hand hygiene in case of diarrhea, indication of hand hygiene, required time), and PPE (types in hospital and insertion of a urinary catheter).

Knowledge about bundles of care:

(A): Knowledge about bundle of care to prevent (VAP) (13 questions) related to: Definition of VAP, angle of the elevated head of bed, oral care, the purpose of elevating the head of bed, changing of air vent humidifier, filling of a humidifier, importance of preventing of deep thrombosis in the legs, indication of uses of peptic ulcer drugs, changing of ventilator circuits, emptying suction bottle, using of much sedative drugs and using of saline solution for the suction.

(B): Knowledge about bundle of care to prevent (CLABSI) (8 questions) related to: Definition of CLABSI time of changing transparent dressing and disinfectant of skin prior insertion for less and more than 1000 grams, changing the line system, changing sterile gauze, disinfect the access port and changing the line system in case of changing the solution.

(C): Knowledge about bundle of care to prevent (CAUTI) (11 questions) related to: Component of CAUTI bundle, definition of (CAUTI), symptoms of urinary tract infection, indication of secured urinary catheter, method of urinal disinfectant, caring of pubic area, placing of the urinary bag, relation of rate of urinary tract infection and urinary catheter, irrigation of urinary catheter in case of obstruction and importance of antibiotic ointment.

Scoring System: Nurses' knowledge assessment was scored according to the key answer as follows: A correct answer scored as one and an incorrect answer scored zero. These scores were converted into a percentage score. Scores of all questions (50 points) were summed up and accordingly the total scoring was categorized into:

Unsatisfactory knowledge (<75%).

Satisfactory knowledge (≥ 75%).

Second Tool: Observation checklists pre/post-program intervention:

This tool was used with permission from the director of each pediatric and neonatal ICUs for assessing nursing performance regarding the bundle of care according to standers of checklists. Observational checklists covered the following 5 procedures:

1. Ventilator Associated Pneumonia (VAP) (6) items.
2. Central Line Associated Blood Stream Infection (CLABSI) (6) items.
3. Catheter Associated Urinary Tract Infection (CAUTI) (6) items.
4. Hand hygiene (10) items.
5. Personal protective equipment.

Scoring System: Each step of a procedure was scored according to the weighing of this step that makes a total score (33 items equal 100%). If any item was done correctly, getting one score while zero score was allotted to the wrong or not done step.

The total scoring system of nurses' performance was classified into:

"Competent" was considered for ≥ 80% and above.

"Incompetent" were considered for < 80%.

Results

A total of 70 nurses(Forty- five nurses from the PICU and 35 nurses were from the NICU) were enrolled at this study.

Part (1): Demographic characteristics of the studied nurses: The mean age and SD of the studied nursing staff age was 30.19±6.34, and the majority of them (91.4%) were females. It was found that 35.7% of them were a technical institute, and 38.6% have ≥10 years of experience. Also, less than one third of them (32.9%) attended a training program on the bundle of care.

Part II: Knowledge of the studied nurses about bundle of care.

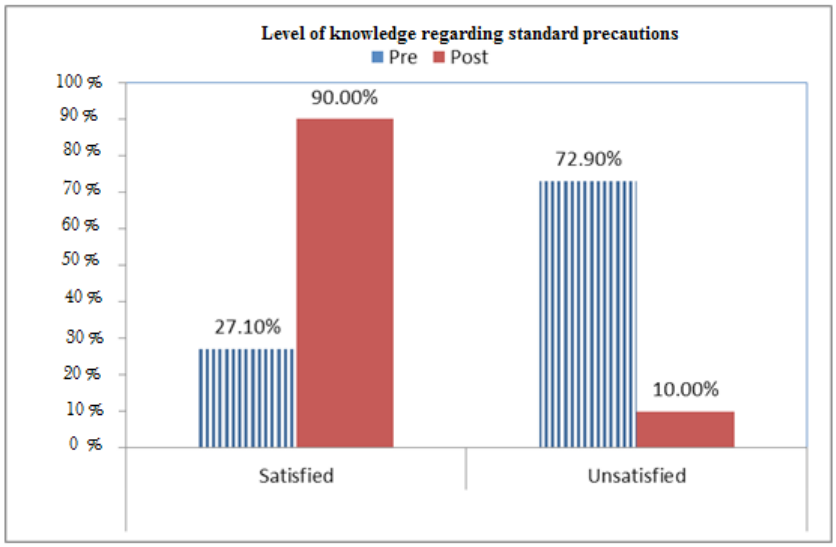

Figure (1): Distribution of the studied nurses according to their knowledge regarding Standard Precautions (SPs) (N=70).

Less than one third of the studied nurse (27.10%) had satisfied knowledge regarding SPs preprogram intervention when compared with the majority (90%) of them had satisfactory knowledge post program intervention. This reflects a statistically significant difference between pre and post application of SPs (p-value <0.001).

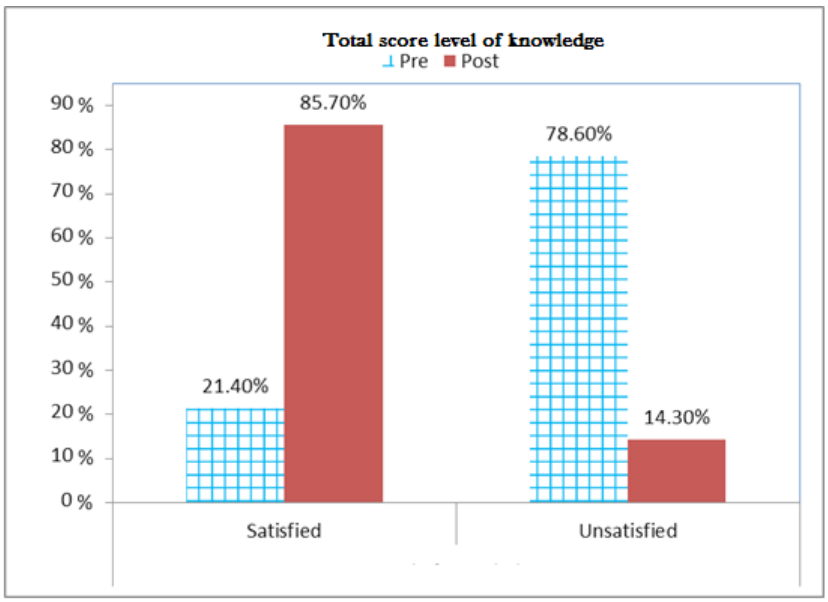

Figure (2): Distribution of the studied nurses' according to their level of knowledge about bundle of care pre post program intervention (N=70).

Less than one quarters (21.40%) of the studied nurses had satisfied knowledge preprogram intervention, compared with more than three fourths (85.70%) of them has a satisfied post program intervention regarding the level of total knowledge about the bundle of care. Also, there was a statistically significant difference between pre and post regarding level of total knowledge about bundle of care (p-value <0.001).

Part III: Practice of the studied nurses about bundle of care.

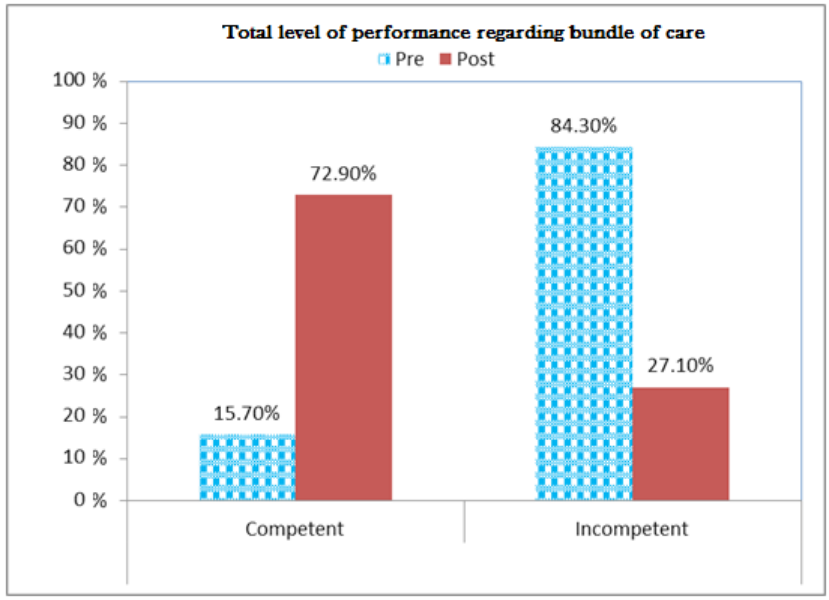

Figure (3): Distribution of the studied nurses according to their total performance regarding bundle of care Pre/post program intervention (N=70).

One quarter (15.70%) of the studied nurses had competent total level of performance regarding bundle of care preprogram intervention compared with nearly three quarters (72.9%) of them had a competent performance post program intervention, there was a statistically significant difference between pre and post -program intervention regarding nurses levels of performance (p-value <0.001).

Part IV: Relation between the studied variables: The studied nurses' total level of knowledge and their demographic data, namely educational level, years of experience, and training courses were statistically significant with p-value (p<0.05).

There were statistically significant relations between the studied nurse's total level of performance about the bundle of care and their demographic data namely educational level, years of experience, and training courses, with p-value (p<0.05).

Table (1): Relation between nurses' level of knowledge and level of performance pre/ post program (N=70)

	Level of performance	Level of Knowledge				Total		Chi-square test	
		Satisfied		Unsatisfied				χ^2	p-value
		No.	%	No.	%	No.	%		
Pre intervention	Competent	11	73.3%	0	0.0%	11	15.7%	47.853	<0.001**
	Incompetent	4	26.7%	55	100.0%	59	84.3%		
	Total	**15**	**100.0%**	**55**	**100.0%**	**70**	**100.0%**		
Post intervention	Competent	51	85.0%	0	0.0%	51	72.9%	31.316	<0.001**
	Incompetent	9	15.0%	10	100.0%	19	27.1%		
	Total	**60**	**100.0%**	**10**	**100.0%**	**70**	**100.0%**		

**p-value <0.001 HS

The studied nurses' level of knowledge pre and post level of performance were highly statistically significant (p<0.001).

Table (2): Correlation between the total score of knowledge and total score of performance pre / post program intervention (N=70).

Total score of performance	Total score of Knowledge	
	Rs	p-value
Pre	0.481	<0.001**
Post	0.625	<0.001**

**p-value <0.001 HS

There is a positive correlation and significant relation between total score of knowledge and their total score of performance regarding bundle of care pre-program and post-program intervention with (p-value<0.001).

Discussion

Pediatric intensive care unit patients develop life-threatening (HAIs) more frequently than other old patients due to their acute illness and invasive device procedures. So, device-associated infections remain a major issue of pediatric patient health safety and outcomes[14]. A care bundle is defined as a group of evidence-based interventions related to a specific condition when applied together significantly improves pediatric patient outcomes. And prevent DAIs in pediatric and neonatal intensive care units[15].

The finding of study nurses was in the age group ≥ 35 years and more with the mean age and SD of the studied nursing age was 30.19, SD ±6.34. These findings were not supported by **Eskander *et al.*(2013)[16]**. Also, our study revealed that more than one-third of them were technical institute. These findings are not supported by **Mohammed (2016)[17].** This may be due to the presence of a technical nursing institute among the hospital and the most of nursing working in the hospital graduated from it. Additionally, our study revealed that more than one-third of them have ≥10 years' experience. These findings are not supported by **Abolwafa *et al.*(2013)[18]** due to most of the studied nursing age more than 35 years and working in ICU since graduation. Regarding the training program, less than one -third of them attended a training program on the bundle of care. This goes in the same line with **Ebied (2011)[19]**.

Concerning gender, the current study demonstrated the dominance of females than males which in agreement with **Atalla *et al.*(2016)[20]**, this result may be due to female were the majority of nursing staff in this hospital and also no male nurses were working in the NICU.

Regarding nurses total knowledge about SPs, the current study revealed that less than one- third of the studied nurse had satisfied knowledge regarding SPs preprogram intervention when compared with the majority of them had satisfactory knowledge post-program intervention statistically significant difference between pre and post regarding level of knowledge on the application of SPs (p-value <0.001).This results in the same line with **Mahmoud *et al.* (2020)[21]**. Indeed, our study showed less than one- quarters of the studied nurses had satisfied knowledge preprogram intervention, improved to more than three- fourths of them post -program intervention This finding is consistent with **Sodhi, (2013)[22]**. Which agreed with our opinion that suggests that the knowledge of the studied nurses increased due to effective program and the availability of handbooks.

According to the total level of performance of the studied nurses, the present study showed that the education program was successful inupdating and enhancing their total performance regarding bundle of care to prevent DAI in PICU and NICU. In addition, this study showed that one quarter of the studied nurses had a competent total level of performance regarding bundle of care preprogram intervention compared to nearly three quarters of them post- program intervention. Also, there was a statistically significant difference between pre- and post- program intervention regarding level of performance (p-value <0.001). This finding was supported by **Ceballos *et al.*(2013)[23]**.

The present study showed that there were significant relations between the studied nurse's total level of knowledge and their demographic data, namely educational level, years of experience, and training courses, with p-value (p<0.05) which was in the same line with **Chen *et al.* (2011)** and **Prasanna (2015)[24,25],** on the other hand it is contradicted with **Mukakamanzi (2017)[26],** who found no significant relation between nurses' knowledge or performance and training on infection control. Also, a significant relation between (qualification) level of education and nurses' level of performance was proven in agreement with a study conducted by **Esposito *et al.*(2017)[27].**As regards nurses' knowledge and their level of performance regarding bundle of care, there were highly statistically significant relations (p<0.001). This result in accordance with a study conducted by **El Sayed Ghonemy et al.(2018)[28]**. The researcher opinion suggests that, as the pediatric nurses' knowledge rises up, their performance increase.

Finally,In Egypt; there is a shortage of nursing staff and professionals. So, knowledgeable nurses are considerably important and required to make perfect performance in pediatric and neonatal care and diminish the hazards of HAI[29,30]. Indeed, Nurses must perform all appropriate preventative evidence-based practice interventions as presented in multiple bundles of care guidelines in order to do these roles, nurses must be well educated on the preventative strategies and be able to translate that knowledge into performance.

Conclusion

Based on the results of the present study, there is a positive correlation and significant relation between the total score of knowledge and their total score performance regarding bundle of care pre and post program intervention. In conclusion, the educational training program reported remarkable improvement in pediatric and neonatal nurse's knowledge and performance toward a bundle of care.

Effects of Modified-Continuous Ambulatory Peritoneal Dialysis (CAPD) Patient's Handling Process on Nurse's Knowledge, Perceived Benefits and Performance in CAPD Care

Prichavijy Promjak[1], Samlee Plianbangchan[2], Ratana Somrongthong[3], Wongsa Laohasiriwong[4]

[1]Registered Nurse, Nan hospital, Ministry of Public Health, Thailand, [2]Distinguished scholar, College of Public Health Sciences, Chulalongkorn University, Thailand, [3]Associate Professor, College of Public Health Sciences, Chulalongkorn University, Thailand, [4]Associate Professor, Faculty of Public Health, Khon Kaen University, Thailand

Abstract

Continuous Ambulatory Peritoneal Dialysis (CAPD) is one of kidney replacement therapy with advantage of home therapy and much cheaper than hemodialysis. Nevertheless, CAPD patients need integrated health care by primary care health facilities to maintain CAPD effectiveness of which has never been assessed and improved. Therefore, this study aims to assess the effect of modified CAPD patient's handling process among nurses at the primary care level. This quasi-experimental study, 47 nurses in sub-district health promoting hospitals (HPHs) of Nan general hospital renal node which completed the standard protocol were assigned to an experimental group, which received the modified-continuous ambulatory peritoneal dialysis (CAPD) patient's handling process intervention. The intervention covered both a case management (CM) and a CAPD web-based program. The comparative groups were 45 nurses in sub-district health promoting hospitals of Pua Crown Prince Hospital renal node. The main outcomes were improvement in knowledge, perceived benefits and CAPD patients care performances of which assessed by t-test, and ANCOVA. There were significant higher scores of knowledge, perceived benefits and performances of nurses in the experimental group applying the "Modified CAPD patient's handling process" than those of the comparative group. Therefore, this intervention should be implemented in other primary care facilities to improve qualities of care for CAPD patients.

Introduction

End-stage renal disease (ESRD) is a chronic illness which is the most crisis and most expensive stage of chronic kidney disease (CKD). ESRD requires renal replacement therapies including hemodialysis (HD), peritoneal dialysis (PD) and kidney transplantation (KT) treatment modalities[1]. The renal replacement therapies (RRT) are expensive therapy, accounting for 1–2 percent of healthcare spending especially in high-income countries with the rising incidence and prevalence of end-stage renal disease (ESRD) modalities treatment[2]. Dialysis modality consisting of HD and PD is one of the most expensive available therapies for ESRD treatment. Hence, the cost of health care is borne by healthcare funder, individual patient and/or their family, making chronic illness a cause as well as a consequence of poverty by household's health expenditure[3] especially among patients with chronic conditions because the health care delivered in a hospital is the costliest aspect of this therapy. Hence, the argument for this approach extends beyond immediately financial benefits to the desire to promote patients' empowerment and autonomy. In most chronic diseases, a component of self-care is essential to use the cost-effectiveness of therapy and the best clinical outcomes[4]. At present with the advantage of home therapy for PD which is less costly than hemodialysis, many governments are encouraging the provision of PD treatment in the community and promoting home dialysis[5]. For frail, elderly patients, the cost of thrice-weekly transport to and from a dialysis facility can be

the most expensive component of their care. Also, the delivery of dialysis in the home environment can create a more favorable 'traveling time' versus 'treatment time' or patient's quality of life trade-off[6,7]. Several research method including a literature review on the CAPD patients on the societal perspective, life-long costs of PD and quality of life reveal that: on societal perspective, PD had a higher cost-effective and cost-utility than HD for all age groups of Thai ESRD patients and treatments provided to younger age groups of ESRD patients with better outcomes and higher cost-effective and cost-utility than those offered to the elderly patients. Therefore, PD is more cost-effective for the Thai government to invest in the economic point of view, societal perspectives such as human rights, equity in health, and humanity concern[8].

Nan province located in the North of Thailand has the main challenges of chronic NCDs especially CKD which was the 4th cause of death of 38.09 per 100,000 population, which was higher than average cause of death with chronic renal disease of the North (average of 27.83 per 100,000 population). In addition, Nan has an increasing trend of ESRD with increased cases of HD and PD from 398 cases in 2010 to 1,488 cases in 2015. Peritoneal dialysis modality in Nan province after the first case in 2009 was increased to 653 cases in 2016 under two renal nodes of dialysis provision in Nan province including Nan general hospital renal node and Pua Crown Prince hospital renal node. The potential advantage of peritoneal dialysis is the home therapy which promotes patient autonomy with less traveling costs for patients than with in-center hemodialysis. However, patients with end-stage renal failure (ESRF) face lifelong physical, psychological and social problems related to their illnesses and treatments. This chronic and irreversible failure of kidney function poses a challenge to nurses and practitioners of related disciplines in the healthcare system at all levels. Dialysis is the major treatment modality to sustain the lives of patients waiting for kidney transplantation. Although the treatment can prolong life expectancy, it impacts the patient's physical, psychological, and social well-being and may impose a considerable burden on patients and families especially the continuous ambulatory peritoneal dialysis (CAPD) which required advance and holistic care by multi-disciplinary teams at all levels for integrated care with various approaches, including patient empowerment, education and counseling sessions, and involvement of family members. CAPD nodes in tertiary and secondary care hospitals have been suggested for improving treatment adherence and outcomes by manager of patient care in community. The previous study was not covered the case management of CAPD care by nurses in the primary care units. In addition, there were few studies that evaluated the effect of case management in CAPD care in renal node hospital only.

The purpose of this study was to examine the effects of modified-continuous ambulatory peritoneal dialysis (CAPD) patient's handling process implement in primary care level by community nurse case management and web-based program that was increased the knowledge, perceived benefits and performance on CAPD care of nurses in a primary care unit (sub-district health promoting hospital) and improved patient care in the long run.

Materials and Method

The quasi-experimental research aimed to implement and assess the effectiveness of the modified-continuous ambulatory peritoneal dialysis (CAPD) patient's handling process in the primary care unit (sub-district health promoting hospital). This CAPD patient's handling process program was based on case management (CM) and integrated with CAPD web-based program. There were two study renal nodes in Nan province including the Nan general hospital renal node and the Pua Crown Prince hospital renal node. They were allocated as an experimental and comparison groups. Additionally, all the sub-district health promoting hospitals were recruited as research setting with the inclusion criteria of 1) providing care for CAPD patients in the community, 2) access to internet. Consequently, nurses in those sub-district health promoting hospitals were recruited as the participants of this research. 47 nurses of 8 sub-district health promoting hospitals of Nan general hospital who met inclusion criteria were sequentially allocated to the experimental group, whereas 45 nurses in 7 sub-district health promoting hospitals of the Pua Crown Prince hospital renal node who met the inclusion criteria were allocated to the comparison group.

This study conducted for18 months. There were three steps including: the first step was the model development based on context of the patients and health facilities, GAP analysis, and systems analysis on CAPD care in the primary care unit. This phase was aimed to develop a new program on CAPD patient's handling process based on case management (CM) with integrated web-based

program. The second step was the formulation and did pretest of both experimental and control groups. The implementation of the modified-continuous ambulatory peritoneal dialysis (CAPD) patient's handling process was applied among nurses in 8 sub-district health promoting hospital of Nan general hospital renal node. The third step was to assess the effectiveness of the implemented program of (CAPD) patient's handling process among nurses in the intervention group and compared with the control group which were nurses in 7 sub-district health promoting hospital in the Pua Crown Prince renal node. The research main outcomes were knowledge, perceived benefits and the performance on CAPD care of nurses at the primary care level.

Intervention: A comprehensive intervention protocol was developed by the researcher and reviewed by nephrologists and experienced renal nurses in Nan general hospital renal node, with further revisions according to their advice. These Modified-CAPD patient's handling process intervention protocol was design covering patient's assessment, nursing care planning, communication, advocacy and health education, health resource management, and service facilitation by the collaboration of multidisciplinary team by Care-map and Clinical Practice Guideline (CPG), and added-up with Web-based program for patient's information and monitoring of CAPD care among hospital renal node and sub-district health promoting hospitals.

The patients in the experimental group received the CAPD standard care and our comprehensive CAPD cares. The clinical practice guideline of CAPD care was the research protocol for nurses in primary care unit as well as a comprehensive assessment of the patient's physical, social, cognitive and emotional needs based on the clinical practice guideline. An individualized education program was conducted by the case manager nurse covering exercise regimen, medication, fluid and diet adherence behaviors, technical procedures for home peritoneal dialysis and prevention of infection. The case manager nurses received a 12-hour training program which included a theoretical input, case training, and web-based program. The nurse set scheduled for home visits and used their professional judgment to define the frequency, intensity, and focus of contacts to meet patient's and caregiver's needs and did follow up the patients for care and assess the patient's progress. If a CAPD patient was at risk of unstable conditions, a referral to the main renal node will be done for proper assessment, investigation, and medical treatment. If needed lastly, referral to the emergency department for urgent treatment was the next step.

The web-based program which links information of CAPD patient was introduced for patient's care plan among main hospital renal node, community hospital, and primary care unit for CAPD care. This web-based program provided a physical assessment of medical information which linked between main renal node and primary care unit procedure treatment, effective care and monitoring. Both comparison and experimental groups, patients received the same routine care during hospitalization. This modified-continuous ambulatory peritoneal dialysis (CAPD) patient's handling process in the primary care unit intervention were an advanced health care technology program combined with diminishing resources for an increased demand for qualified nurse case managers in primary care level who can manage complex cases for the best interests of the CAPD patients that could save time, money, improved quality of life and treatment outcomes of the patients.

Data collection and measurement tools: Measurement tools of CAPD care among nurses were questionnaires to assess knowledge, perceived benefits of CAPD care. The questionnaire consisted of two parts. The first part was the participant demographic and socioeconomic information including age, gender, and education level. The second part was knowledge and perceived benefits of CAPD. The performance of CAPD care was assessed by a check list questionnaire which assess the medical record and health service program in each sub-district health promoting hospital.

All of assessment tools were developed by the researcher. The analysis of Item-objective congruence index (IOC) was conducted for content validity of the questionnaire and was revised based on the expert's recommendation. The reliability was tested among 30 participants who had similar characteristics with the study population at the primary care level. The Cronbach alpha coefficient of the questionnaire was 0.86 scores.

Data Analysis: The Chi-square test was used to compare the differences in demographic data (Category variable) between experimental and comparison groups. The t-test was utilized to compare the difference of the sum of knowledge score, perception, and performance of CAPD care. In addition, the ANCOVA was used to assess the effectiveness of the CAPD handling process program covering baseline and post-intervention

period while the statistically significant ($p < .05$) were considered significant.

Ethical Consideration: This research was approved by the Chulalongkorn University's Ethics Review Board. The certificate of approval number was COA. No.096.1/59 Additionally, office of Nan Provincial Public Health also has permission for this study in Nan province and also all study participants were signed informed consent forms before data collection and implementation of the intervention. The information in these studies were analyzed, synthesized and presented for academics only.

Results

A total of 92 nurses were included in the analysis, 47 among the experiment and 45 among the comparison group. Among these participants, 94.57% were female. Their ages ranged from 25 to 56 years, with a mean of 43.34 years (S.D. 7.03) in experimental group whereas it was 40.71 years (S.D. 7.08) in the comparison group. Almost all of them finished bachelor's degree in nursing (95.74% among experimental and 95.56% among comparison groups. Only 4.26% in experiment and 4.44% in comparison groups graduated a master's degree in nursing. The personal characteristics of experimental and comparison groups including sex, age, marital status, education, official status, received community nursing training, and experience of work in community were comparable ($p>0.05$).

Knowledge of CAPD care Assessment: The knowledge assessment covered PD exchange, steps for PD exchange, activity of CAPD patient, drugs use and health education for self-care of CAPD patient, home visit care and knowledge on drug use such as erythropoietin injection for anemia treatment from iron deficiency in chronic renal disease patients. The level of knowledge on CAPD care of the experimental and comparison groups at baseline, the highest proportion of both groups was at average level (34.04% among experiment and 35.56% among comparison groups). However, after intervention, the level of on knowledge CAPD care in the experimental group were much more improved than the comparison group. All of the nurses in the experimental group had high level of knowledge whereas only 46.67 % of the comparison group had high level of knowledge, followed by 40.00 % with average level and 13.33 % had low level of knowledge (Table 2).

Table 2 Level of knowledge on CAPD of experimental and comparison groups at baseline and after intervention

Level of knowledge assessment on CAPD care	Baseline				After intervention			
	Experimental Group 47 participants		Comparison Group 45 participants		Experimental Group 47 participants		Comparison Group 45 participants	
	Number	(%)	Number	(%)	Number	(%)	Number	(%)
Low (<60 scores)	10	21.25	5	11.11	0	0.00	6	13.33
Average (60-79 scores)	21	44.68	24	53.33	0	0.00	18	40.00
High (≥ 80 scores)	16	34.04	16	35.56	47	100.00	21	46.67

Perceived Benefits of CAPD care: Baseline information of perceived benefits of CAPD care illustrated no significant difference between nurses in experimental and comparison groups. The highest proportion of perceived benefits of CAPD care at baseline was at fair level (40.43 % among experiment and 33.33% among comparison groups) followed by good perception on benefits (29.79 % and 28.89 among experimental and comparison groups) and similar proportion had poor perceived benefits (29.79% in experiment and 37.78% in Control groups). However, after intervention, the perceived benefits of CAPD care in the experimental group was much higher, of which all the nurses in this group had good level of perceived benefits when compared with 55.56% of good level, and 44.44% of fair level in the control group respectively (Table 3).

Table 3 Level of perceived benefits of CAPD care between experimental and comparison groups at baseline and after intervention

Level of Perceived benefits of CAPD care	Baseline				After intervention			
	Experimental Group 47 participants		Comparison Group 45 participants		Experimental Group 47 participants		Comparison Group 45 participants	
	Number	(%)	Number	(%)	Number	(%)	Number	(%)
Poor (<60 scores)	14	29.79	17	37.78	0	0	0	0
Fair (60-79 scores)	19	40.43	15	33.33	0	0	20	44.44
Good (≥80 scores)	14	29.79	13	28.89	47	100.00	25	55.56

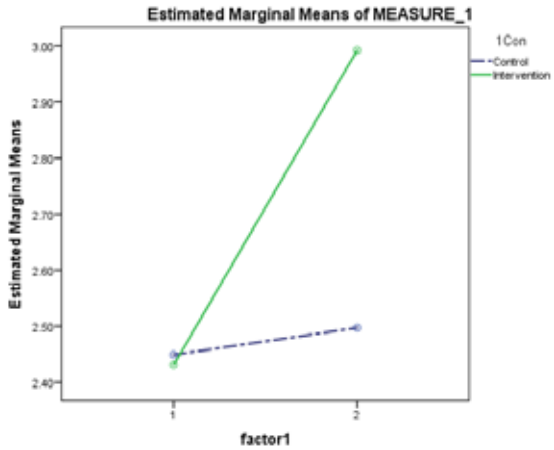
Effect of the program on knowledge, perceived benefits of CAPD care and performance on CAPD care: At baseline the level of knowledge on CAPD among comparison group was not significantly higher than that of the experimental group, whereas the perceived benefit score and performance of CAPD care among the experimental was non significantly higher that the comparison's group. The model using ANCOVA with controlling for covariate variables including age of nurses, training in nursing and duration of working experience in sub-district health promoting hospital between the experimental and comparison groups at baseline and post intervention (4 months after applied intervention program). There was a statistically significant difference between the intervention and control groups (p-value<.05). Both knowledge and perceived benefits of CAPD care were significantly higher in the experimental than that of the control groups at similar magnitudes with the mean difference of 4.41 (3.73-5.09 scores) on knowledge and 3.77 (3.21-4.44 scores) on perceived benefits of CAPD care. There was more improvement on CAPD care performance among the experimental group when compared with the controls with the mean difference of 17.12 (14.51-19.73 scores) (Table 4).

Table 4 Mean difference adjusted for baseline measurements, sex age, educational status, training in nursing, duration of working experience as a nurse and duration of working experience in sub-district health promoting hospital for experimental and comparison groups using the analysis of covariance (ANCOVA) on Knowledge, Perceived benefits and Performance of CAPD care.

Variable	Duration	Experimental Group		Comparison Group		Mean difference	Adj. Mean difference	95% CI	P-value
		Mean	S.D.	Mean	S.D.				
Knowledge of CAPD care	Baseline	14.06	2.83	14.44	2.55	-0.38	NA	NA	NA
	After	19.10	1.04	14.91	2.73	4.19	4.41	3.73 - 5.09	<0.001
Perception of CAPD care	Baseline	25.31	2.68	25.04	1.97	0.27	NA	NA	NA
	After	34.02	1.07	30.13	1.54	3.88	3.77	3.21 - 4.33	<0.001
Performance of CAPD care	Baseline	80.10	16.87	78.28	17.69	1.81	NA	NA	NA
	After	111.17	2.79	94.31	7.88	16.85	17.12	14.51-19.73	<0.001

Despite increasing the knowledge of CAPD care in all intervention and the control group but strongly increasing in the intervention group. Nevertheless, the performance of CAPD care was increasing in the intervention group only (Figure 1).

Knowledge of CAPD care



Performance of CAPD care

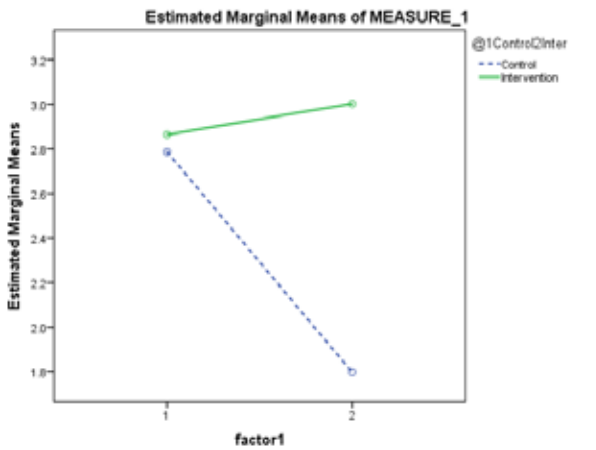


Figure 1 Change over times on Knowledge and Performance of CAPD care scores between the intervention and control group

Discussion

This study developed and implemented as well as determined the effectiveness of the CAPD handling process program on knowledge, perceived benefits and performances of CAPD care among nurses in order to strengthen the performance of CAPD care in primary care level. The research results indicated statistically significantly increase in knowledge of nurse in sub-district health promoting hospital. Considering the baseline knowledge on CAPD care of community nurses, the intervention and the control groups were not significant difference. It may be because all nurses acquired knowledge on CAPD care on annual training from hospital renal node. The experimental group had a little lower knowledge level more than the comparison group at baseline. However, after intervention, all of nurses in the experimental group had hid high level knowledge on CAPD care whereas less than half of those in the control group had high level. It may be because the intervention group received additional trainings as well as applied eHealth by web-based application[9] for nurses in primary care level which linked information from nephrologist and CAPD nurses in hospital renal node. This finding is similar with the study of web-based learning in practice settings among nurses in United Kingdom[10] that increased their knowledge of patient care. In addition, the nurses also reported an increase in their ability to transfer their knowledge to practice through improved emotional and psychological support of patients and their relatives. The participants in the experimental group also worked in an integrated health care procedure with specialist in hospital renal node by setting the CAPD care systems in sub-district health promoting hospitals.

The assessment on perceived benefits of CAPD care among nurses in sub-district health promoting hospitals illustrated a significant increase in perceived benefits of CAPD care in the intervention group. This might help improving their performance on CAPD care. In 2017, the Ministry of Public Health launched the policy on service plan to increase quality of care in critical diseases especially the service plan for CKD of which improvement of standard of CKD care among excellence center well as primary care level are essential. Most importantly, the performance of CAPD care was much improved in the experimental group after intervention which was similar with a study among case manager nurses conducted by Tao X, Chow SK, Wong FK[11] reported the improvement of care performance for hemodialysis patients in community as well as the

practice guideline for community nurse with increased competency for patient care in community as well[12].

Conclusion

The "Modified CAPD patient's handling process" intervention which included both the program of case manager nurse and web-based program of eHealth was effective in improving the nurse's knowledge and perceived benefits of CAPD care as well nurse's CAPD care performances among nurses who worked in primary care level. However, it is recommended to implement the Modified CAPD patient's handling process in other setting with the aim of improvement to be fit with wider context. This study developed a CAPD patient's handling process as an additional existing standard CAPD care with case management of community nurse for CAPD care as well as a CAPD web-based program which is the online operation. This technology might be restricted to primary care unit with poor resource internet.

Abstract

The rapid development of information and communication technology has brought changes to the mechanism for storing electronic medical records (EMR). EMR is very important to protect and provide comfort and convenience for health services. However, it is very susceptible to be abused by hackers. This study aims to harmonize amongst relevant laws on EMR and to identify the legal protection of EMR from abuse by hackers. This research uses a normative research method to harmonize legal norms and regulations related to EMR that already exist in Indonesia. Legal protection of EMR in Indonesia has not been implemented proportionally even though the regulation on EMR has been stipulated clearly in the Minister of Health Regulation No. 269/ 2008 concerning Medical Records and various relevant Laws on it. There are no derivative laws related to EMR as mandated by the Minister of Health Regulation No. 269/2008 which becomes an obstacle to the effective implementation of EMR. The existence of an EMR is Also very susceptible to be abused by hackers. So, cyber security is needed for health workers, both individually and institutionally to protect EMR. In conclusion, EMR has been regulated in Indonesian Laws, but it has not been governed into derivative laws to be implemented a proportionally. Therefore, harmonization those laws will narrow the gaps amongst them. Further norms and regulations regarding EMR are needed to create cybersecurity which is potential to be hacked.

Keywords: *Legal Protection; Electronic Medical Records; Hackers.*

Introduction

The development of information technology today gives a colour to the world of health. The use of electronic medical records (EMR) is one form of these developments. EMR is a form of innovation in responding to the challenges of the times in the health sector. Medical records in the past are identical to paper administrative documents containing the patient's identity, history and actions given by a doctor to a patient. With EMR, health workers can obtain patient medical history data more easily, regardless of distance and time, the application of EMR has even been adopted in hospitals in various countries since 1999[1].

In 2003, RAND Health Information Technology (HIT) began conducting research related to the role and importance of EMR in improving health services and informing the government to maximize the benefits of EMR and increase its use. The results of this study indicate the benefit of implementation of EMR and its network can save more than 81 million dollars per year, which can increase productivity and efficiency in health care[2].However, it remains to be aware that the use of systems based on electronics and the internet is very vulnerable to be abused and hacked by irresponsible parties.

EMR consists of notes and documents including the patient's identity, examination results, medications that have been given, and other actions and services that have been provided to patients[3].The presence of multiple personal identities stored in the EMR is very susceptible to the misuse of data by parties who are not responsible. This can be taken place because the EMR repository can be accessed by the third parties – called hacker – and the tool to access it is computer and internet as a media. Therefore, some actions shall be done to protect on patient data, including regulation approach.

In general, regulations related to EMR has been governed in the Minister of Health Regulation

Number 269 of 2008 concerning on Medical Records (PermenkesMedical Records). In this regulation, it is explained that EMR documents, which is the data are qualified as personal data of a person need to be maintained and kept confidential to avoid data misuses. The content of a patient's medical record, basically, contains juridical consequences in the form of the patient's personal identity. It must, then, be kept confidential[3]. All information in medical records is confidential, therefore, its use must be with the patient's consent, except[3]for the purposes of education and research which are implemented for the benefit of the state

EMR is the use of information technology tools for collecting, storing, processing and accessing data stored in patient medical records in hospitals in a database management system that collects various sources of medical data[4].Some modern hospitals have even combined EMR with the Hospital Management Information System (SIMRS) application which is the main application that not only contains EMR but also has added features such as administration, billing, nursing documentation, reporting and a score card dashboard.

If you look more deeply, the use of technology, namely computers and the internet, allows cybercrime to occur against patient EMR. Therefore, it is considered important to protect the EMR of patients, where this protection aims to safeguard personal data and broadly protect national health system data from abuse and cybercrime by those who want to hack. In general, the implementation of EMR has been categorized as an electronic document as stipulated in the Law Number 11 of 2008 as amended by the Law Number 19 of 2016 concerning Information and Electronic Transaction. It means that EMR as a norm and law has been accommodated in this Law, although it has not been specifically explained regarding EMR[5].

Misuse of EMR is a legal issue to be discussed by among legal practitioners in this modern era, including in Indonesia. Some debates coming from many parties that EMR does not have a clear legal standing, especially with regard to guaranteeing against elements of privacy, confidentiality and information security in general[4].The result of this controversy raises a distrust of the EMR system. As it is known that a person's data, especially medical history data, is very private and will be a danger if it is accessed by irresponsible parties. Of course, this will be very detrimental to the victim, particular in this case of the patient's data has leaked to the party who should be prohibited from accessing the information.

Therefore, the focus of this paper is to analyse various regulations related to the implementation of EMR. Starting from general regulations such as the Law Number 29 of 2004 concerning Medical Practice (Law on Medical Practice) and the Law Number 11 of 2008 as amended by the Law Number 19 of 2016 concerning Information and Electronic Transaction, to specific regulation as if the Permenkes Medical Records. Those laws then shall be harmonized in order to carry out the important reasons why EMR is pivotal in medical practice and why it shall be protected. Indeed, the last point to be underlined in this paper is the identification of various cyber-rime vulnerabilities that will occur from misuse in the EMR.

Materials and Method

This study is a normative study to analyze various EMR regulation, which is well adapted to the analysis of relevant norms and principles. Those regulation are reference sources coming from legal materials called laws and the principles of law, and a scientific journal. All those legal materials will be analyzed qualitatively to deal with the EMR legal issues. The various materials obtained are then analyzed qualitatively to lay down EMR in the right position as an advanced development of medical records, before technology gets involved in the area of medical records.

Result and Discussion

Harmonization of Medical Records Law:

Obligation to Make Medical Records: Medical records refer to the Law Number 29 of 2004 concerning Medical Practice. Article 46 paragraph (1) of the Law Number 29 of 2004 states that an obligation for doctors and dentists to have medical records of the patients in carrying out their medical practice. In the explanatory of the Article 46 paragraph (1) further explains the definition of "medical record" as a file containing notes and documents about the patient's identity, examination, treatment, actions and other services that have been provided to patients. Medical records should be equipped with the affix name, time, and signature of the person who provides services or actions.

Furthermore, Article 47 of the Law Number 29 of 2004 explains that[6]: Medical record documents as

referred to in Article 46 belong to a doctor, dentist, or health service facility, while the contents of the medical record are the property of the patient. Due to the contents of the medical record is belong to the patient, it is the duty of the doctor or dentist and the head of health service facilities to keep and maintain its confidentiality.

As it is known, medical records have a very important role and become an indicator of good and responsible medical practice, which shows the good performance and discipline of health workers. The medical record contains various data in the form of patient identity and all actions taken (from the beginning) to patients in the context of providing health services. The recording must be listed chronologically, systematically and accurately, so that it can provide a description of a person's disease information, investigative actions carried out on him/her, information on management plans, observational records, clinical and treatment results, approval or rejection, and summary of discharge[7].

Regarding to EMR, it is specifically regulated in the Minister of Health Regulation (Permenkes) Number 269 of 2008 concerning Medical Records (Permenkes Medical Records). Even though in the explanatory of article 46 paragraph 3 of the Medical Practice Law has provided space for the implementation of EMR, the clear position of EMR basically is stipulated in the Permenkes on Medical Records. This Permenkes states that if the medical records created in electronic form, the signature of the doctor or dentist or other health professionals can be replaced by using a personal identification number. This is very important because Article 2 of the Permenkes provides a legality basis for the implementation of medical records which must be written, complete and clear or electronically[3].It means that the contents of the medical record should be in written form and is belong to the patient which consisting of notes and documents regarding the patient's identity, examination, treatment, actions and other services that have been provided to the patient[3].According to the Permenkes, the contents of medical records can be categorized as categories for out-patients, in-patients, emergency services, disaster situations and for the services of a specialist doctor or specialist dentist. The medical records have minimally contents such as personal identity, complaints of illness, and health measures are necessary[3].

Nowadays, the implementation of EMR has been able to be synergised to a hospital information system (SIRS) electronically. The SIRS may be contained various applications such as: (a) Application of Mobile and Web; (b) Server Applications; (c) Receptionist Application; (d) Telemedicine applications; (e) Update Medical Registration; (f) Application in the Medical Registration Room; (g) Application of Hospital Information Systems; (h) Application for Recording Doctor's Salary; (i) Result of Pathology Laboratory Test; and (j) Application of Radiology Test Results. With data storage based on Cloud Computing, this can make it easier for hospitals to store large data[8].

According to WimmieHandiwidjojo, the use of EMR has enabled information technology equipment for the collection, storage, processing, and accessing data stored in the EMR of patients in hospitals within a database management system that collects various sources of medical data, since 2009. Even some modern hospitals have combined EMR with the Hospital Management Information System (SIMRS) application which is the main application that not only contains EMR but has added features such as administration, *billing*, nursing documentation, reporting and a score card dashboard[9].

EMR as an Electronic Document: The existence of EMR is a development of technological advances in the health sector which is also part of the mandate of the Indonesian Medical Code of Ethics. Article 21 of the Code of Ethics explains that it requires doctors to keep developments in medical or health science and technology. According to IkaMeilia, every doctor should be willing and able to document patient management carried out in the EMR in accordance with applicable regulations[1]. As an implication of the development of electronic technology, the provisions in EMR are closely related to electronic documents stipulated in the Law Number 11 of 2008 as amended by the Law Number 19 of 2016 concerning Information and Electronic Transaction.

Article a point 4 of the Law Number 11 of 2008 as amended by the Law Number 19 of 2016 concerning Information and Electronic Transaction (the Information and Electronic Transaction Law) stipulates that electronic documents are defined as "any electronic information that is created, forwarded, sent, received, or stored in analogue, digital, electromagnetic, optical, or the like, which can be seen, displayed, and / or heard through a computer or electronic system, including but not limited to writing, sound, images, maps, designs, photographs or the like, letters, signs, numbers, access codes, symbols or perforations that have meaning or meaning or can be

understood by those who are able to understand them." Referring to the document electronic as stipulated in the Article 1 of the law Number 11 of 2008, EMR can be categorized as an electronic document. The legal implication of this is that the regulations related to EMR have an intersection stipulated in the Information and Electronic Transaction Law. So that all legal actions related to the abuse of this EMR can be subjected to sanctions of the Information and Electronic Transaction Law.

The crucial point from the harmonisation of the EMR as stipulated above, it cannot be denied, then, the protection of medical records is very necessary to neglect EMR misuse from unauthorized parties and for the sake of legal evidence[10]. However unfortunately, after 12 years since this legal basis was established, there are no derivative regulations of the Permenkes to become the legal basis for the enforcement of EMR in Indonesia as stated in Article 2 paragraph (2) the Permenkes on Medical Records. Even though this is very important to strengthen the legality of EMR implementation[7].

Abuse Vulnerability of EMR: EMR collect various medical history data, patient care or medication and it is very personal to the patient. The existence of various personal identities stored in EMR is very vulnerable to misuse of data by irresponsible parties. Medical record documents, both conventional and electronic, are confidential documents belonging to patients, so they must be protected as best as possible. In this case, the family or other parties who want to know this medical record need to get the consent of the patient or the patient's attorney. So that privacy of patient is very much guarded. (Rokhim 2020) EMR can be stored in an electronic device such as a computer or other electronic data storage device, including the Cloud.

EMR has at least two forms of security against the privacy of medical records, namely authentication and authorization. Authentication is a form of ensuring that the party authorized to enter and use the system. It can be in the form of a password, access card or more sophisticated with biometrics such as fingerprints. Meanwhile, in terms of authorization, only certain parties have the authority to access EMR. It means that not every officer in the health facility is allowed to use the existing EMR network system. Each user also has different access authority restrictions. This can increase EMR's privacy security[1].

In general, the misuse of EMR data can be categorized as cyber-crime. It is classified into two forms, namely; (a) crimes via computer media, Flash-disk- or various other hard storage devices; and (b) crime via hacking by the EMR Cloud based system. To guarantee the legal protection of patient data, therefore, it is very important to understand these two things to prevent and take legal measures that can be taken to protect EMR from misuse by the irresponsible party.

Some scholars use the terms "computer misuse", "computer abuse", "computer fraud", "computer-related crime", "computer-assisted crime", or "computer crime". However, scholars at that time generally accepted the use of the term "computer crime". It was because it was considered more extensive and commonly used in international relations. The British Law Commission defines "computer fraud" as computer manipulation in any way done in bad faith to obtain money, goods or other benefits or intended to cause harm to other parties (Suhariyanto 2012)[11].

In this case, those who can obtain EMR data are those who can legally access the data, such as health workers and patients themselves in accordance with applicable regulations. One such case was at Howard University Hospital, Washington in which data security is not properly guaranteed causes data leakage. In this case, a staff member at the hospital has access to patient data, name, address and patient medical record number and sells the information to insurers. Another case is a worker managed to steal a laptop and download 34,000 patient data on his personal laptop in a hospital. EMR data is not encrypted. It means that anyone can guess the data password and can access patient data. Based on this, according to Meilia, it becomes a challenge in the medical world to improve the safety of patient EMR data[1].In this context, the EMR abused can be categorized as Computer Crime because it uses a computer device as a tool to conduct crime. In this case a computer is a tool to commit a crime to gain certain advantages that harm other parties.

Storage system based EMR Cloud computing is one of development technology. In this context, to store EMR no longer requires a separate server because it has been supported by the virtual server. This cloud-based storage method can save infrastructure costs and can easily share data with various health care facilities. However, on the other hand, EMR data storage based on the Cloud is very vulnerable to the risk of hacking[11]. As

it is known, a hacker can hack a network system so that it is possible to access data from a network system that has been hacked. This applies to any network system that is open and accessible to anyone. If EMR data exists in an internet network such as those based on the cloud, then there is a great potential that these data can be hacked.

In the typology of cybercrime, hackers against cloud-based EMR systems can be categorized as occurring, namely: (a) offenses against the confidentiality, integrity and availability of computer data and systems, such as illegal access (hacking / cracking), illegal data acquisition (data espionage), Illegal interception, data interference, system interference[12]. To reduce this risk, it is necessary to have a cybersecurity system that is qualified and evaluated and tested regularly network security[10].

Regarding to abused EMR via hacking, in Article 30 paragraph (1), paragraph (2) and Paragraph (3) jo. Article 46 paragraph (1), paragraph (2) and paragraph (3) of Law No. 11 of 2008 concerning Electronic Information and Transactions as amended by Law No. 19 of 2016 concerning Amendments to Law No. 11 of 2008 concerning Information and Electronic Transactions have regulated legal sanctions on hackers, or people who deliberately access other people's computers or certain electronic systems unlawfully, with various criminal sanctions and fines that can be prosecuted to hackers. Referring to those articles on the Information and Electronic Transaction Law, which is then linked to EMR, it is an electronic information and / or electronic document and anyone who misuses a patient's EMR data can be subject to the article. However, this is a step when the criminal act has occurred. Even though there should be preventive steps beIn EMR practice, debate on legal standing of EMR is still taking place. Some regulation such as the Medical Practice Law and/or the Permenkes on Medical Records do not derive to lower regulation to show EMR position to be more practical. Article 2 paragraph (2) Permenkes on Medical Records states that EMR as an alternative to recording medical records will be regulated in a separate regulation, but until today the regulation has not yet existed. Even though EMR system has been used by several hospitals in Indonesia such as Dr.Soetomo Hospital[13] Surabaya and RS Paru Jember[14]

The absence of a clear legal standing in EMR security system is indicative of a lack of trust in the security of patient data. On July 20, 2018, for example, hackers pretend to be patients visited the clinic database and clinic of SingHealth, the largest health operator in Singapore. The hackers then illegally accessed and downloaded data on 1 May 2015-4 July 2018. The medical information data of 1.5 million Singaporeans including data belonging to Prime Minister Lee Hsien Loong was hacked into[15].

Conclusion

Harmonization of law is required related to the protection of EMR data, which has a legal basis as stipulated in the Medical Practice Law, and specifically in the Permenkes on Medical Records. As an electronic document, EMR's position is also directly regulated in the Information and Electronic Transaction Law. In addition, special regulations are needed related to EMR itself which is the mandate of the Permenkes on Medical Records. The aim of derivative regulationto strengthen the legal standing of the EMR and to neglect abuse of EMR done by the irresponsible parties either via computer crime or via hacking.

Conflict of Interest: The Authors declare that there is no conflict of Interest.

Call for Papers / Article Submission

Medico-Legal Update invites articles, case reports, newspaper clippings, report medico legal activities to update the knowledge of readers in scientific disciplines such as Forensic Medicine, Forensic Sciences, Environmental Hazards, Toxicology, odontology, Anatomy and law etc.

The following guidelines should be noted:

- The article must be submitted by e-mail only. Hard copy not needed. Send article as attachment in e-mail.
- The article should be accompanied by a declaration from all authors that it is an original work and has not been sent to any other journal for publication.
- As a policy matter, journal encourages articles regarding new concepts and new information.
- Article should have a Title
- Names of authors
- Your Affiliation (designations with college address)
- Abstract
- Key words
- Introduction or back ground
- Material and Methods
- Findings
- Conclusion
- Discussion
- Acknowledgements
- Interest of conflict
- References in Vancouver style.
- Please quote references in text by superscripting
- Word limit 2500-3000 words, MSWORD Format, single file

All articles should be sent to: **medicolegalupdate@gmail.com**

About The Journal

Print-ISSN:0971-720X, Electronic - ISSN:0974-1283, Frequency: Quarterly (4 issues in a year)

Medico Legal Update is a journal which brings latest knowledge regarding changing medico legal scenario to its readers. The journal caters to specialties of Forensic Medicine, Forensic Science, D. N. A. fingerprinting, Toxicology, Environmental hazards, Sexual Medicine etc. The journal has been assigned international standard serial number (ISSN) 0971-720X. The journal is registered with Registrar of Newspapers for India vide registration numbers 63757/96 under Press and Registration of Books act, 1867. The journal is also covered by EMBASE (Excerpta Medica Database) from 1997 and by INDEX COPERNICUS, POLAND.

Medico-Legal Update is a quarterly peer reviewed journal. The journal has also been assigned E- ISSN 0974-1283 (Electronic version). The first issue of the journal was published in 1996.
