KESIMPULAN

- Terjadi dekomposisi jaringan lignoselulosik yang signifikan untuk limbah TKS yang berumur 2 tahun.
- Proses dekomposisi TKS didominasi oleh spesies bakteri yang tidak dapat dikulturkan dan belum teridentifikasi.
- Bakteri dari filum proteobakteria, terutama γ -proteobakterium mendominasi komunitas populasi bakteri.
- Biodiversitas/keragaman populasi fungi selama proses dekomposisi lebih rendah daripada bakteri, namun dominasi spesies fungi tertentu pada setiap tumpukan sangat tinggi.

Abstract

Oil Palm Fruit Empty Bunches (FEB) is lignocellulose biomass, which is often used as green manure in oil palm plantation. However, it is constrained by the composting time of the FEB in the field. To overcome the problem we have studied the microbes, which involve in the composting process of FEB. We developed the isolation method using natural substrate derived from FEB. By modification of cellulose congo red agar (CCRA), in which the FEB powder is used instead of CMC, we have succeeded to show that TKSCRA (FEB congo red agar) could be used in determining the lignocellulolytic activity of isolates.

Key word: Oil palm Fruit Empty Bunches, Lignocellulose

PENDAHULUAN

Kalimantan Timur merupakan salah satu daerah pengembangan sawit di Indonesia yang terpusat pada 4 (empat) Kabupaten (Kab. Paser, Kab. Penajam Paser Utara, Kab. Kutai Barat

Abstract

Empty Fruit Bunch (EFB) of oil palm is used by Palm Oil Mill (POM) as boiler fuel or fertilizer for oil palm plantation. Fast growing of oil palm plantation area produces huge amount of EFB, which then becomes spectacle in solid waste management. Decomposition of EFB is very slow and microbial activity on EFB decomposition also caused greenhouse, in which methane is produced. To figure out the problems, a study on physico-chemical characteristic of decomposed EFB and microbial succession in the decomposition process of EFB was conducted. Microbial diversity from 3 EFB piles (6, 12, and 24 months of age) from two different POM in Indonesia were determined using PCR-DGGE of 16S and 18S rDNA for bacteria and fungi, respectively. The result showed that decomposition of EFB is dominated by non-cultured bacteria and not reported yet. Bacteria from proteobacteria dominated the bacteria community in EFB pile of 6-24 months. The diversity of fungi community is lower than bacteria, however domination of certain fungi in each EFB pile is very high.

Key words: 16S rDNA, 18S rDNA, PCR-DGGE, proteobacteria

INTRODUCTION

Empty Fruit Bunch (EFB) of oil palm is the highest solid waste produce (22-23 % from total fruit bunch) in oil palm industri (Faizzi *et al.*, 2002). The usage of EFB for boiler fuel or as green fertilizer is not efficient anymore because of the extensification program of oil palm
